as to size, carried to curing-houses, and by some placed on shelves to dry or cure out. The bulbs must be stirred or have their position changed every few days to prevent mold and rot. This stirring wears or breaks off the roots and tops of a good percentage of the bulbs, making a less slightly bulb, though not injuring its flowering property. The better and more modern way is to gather them by the roots in bunches of about ten, tie them together with a small cord and hang them upon frames, walls, and overhead of house and allow them to cure without disturbing them during the process of drying. While this would seem a rather expensive way, it really costs but a few cents a thousand, being done by small negro children at nominal wages. In recent years, artificial heat of 80° to 100° by means of furnace and flues similar to those used in tobacco-barns has been introduced, to hasten curing. Four to eight weeks are required properly to cure the bulbs for shipping, so that the first shipments begin to move about December 1 to 10. Before shipment the bulbs are again sorted in order to get out any undersized bulbs that may have been overlooked; they are also counted and packed in paper-lined barrels, holding from 700 to 1,300, the number varying with size of bulbs and size of barrels. About 200 barrels, or 150,000 to 175,000 bulbs, constitute a carload. The bulk of the exports go through New York dealers. A few are exported direct.

The variety mostly grown is Dwarf Pearl. This sends up a flowering stem about 15 inches long, the blossom being double. The Tall Double is similar except that the flowering stem is longer, about 24 inches or over. The White or Orange Flower has a long stem, with the blossom single or resembling the blossom of an orange tree. The Albino, a freak from the Pearl, is a dwarf single or orange-flowered variety, but its tendency in other latitudes is to go back to the double type, and consequently is likely to disappoint the grower who expects a single blossom. The foliage of all the above is a rich green. The variegated-leaved variety has a beautiful stripe of golden or silver hue on the outer edge of the foliage. The blossom is single and the habit is dwarf. The tuberose is treated as an annual and has to be replaced each season.

A "number one" bulb (referring to size) is not less than 4 inches in circumference and measures up to 6 inches and over. "Mammoth" bulbs are 6 to 8 inches in circumference; only a very small part of the crop will attain such measurement. A "number two" bulb is less than 4 inches and over 3 inches in circumference, and while in the South these will bloom as well as the larger bulbs they are not much sought by the northern dealers. The tuberose is a rather slow grower; hence in the North, where the frosts are much earlier than in the South, it is likely to get caught before its spike of bloom matures. To succeed in getting flowers in the North they should be started in pots under glass or in rooms free of frost in April and transplanted to open ground in early June. The soil should be deeply pulverized. Choose a sandy loam if possible, and fertilize with manure containing a good percentage of potash. Keep the earth about the plant thoroughly stirred and do not let the plant suffer for moisture.

H. E. NEWBURY.
W. R. NEWBURY.†

POLIOTHÝRSIS (Greek, *polios*, white or grayish white and *thyrsos*; referring to the grayish white color of the inflorescence). *Flacourtiaceæ*. A deciduous tree allied to *Idesia* and differing chiefly in the valvate sepals, the 3 styles and in the capsular fr. Fls. monoecious, apetalous, with ovate to lanceolate valvate sepals; staminate fls. with many free short stamens and a minute rudimentary ovary; pistillate fls. with a superior ovary, 3 reflexed styles 2-parted at the apex: fr. a caps. dehiscent into 3-4 valves; seeds many, winged. Similar in habit to *Idesia*, but lvs. longer,

purplish when unfolding; it is apparently of the same hardness, as it has proved hardy in favorable localities at the Arnold Arboretum. Its cult. and prop. is the same as *Idesia*. The only species is *P. sinénsis*, Oliver. Slender tree, to 40 ft.: young branchlets pubescent: lvs. long-petioled, ovate to ovate-oblong, acuminate, 5-nerved at the base, dentate, pubescent below or nearly glabrous, 3-7 in. long: fls. in loose terminal panicles 4-8 in. long, greenish white, $\frac{1}{4}$ - $\frac{1}{2}$ in. across; sepals ovate to lanceolate, whitish tomentose outside: caps. $\frac{3}{4}$ in. long, ovate-oblong. Cent. China. July. H.I. 19:1885.

ALFRED REEDER.

POLLEN, POLLINATION. Pollen is the fecundating material contained in the anther, usually in the form of many very small grains. In many orchids it is in the form of masses of cohering parts or grains, termed pollinia. Pollen represents the male or fertilizing phase of reproduction in seed plants. Forms of pollen are shown in Figs. 3094-3097.

All gymnosperms (conifers, and the like) and angiosperms (true flowering or ovary-bearing plants) normally reproduce by means of seeds. For the fertilization of the ovule, in order that seed may result, the intervention of the pollen is necessary. The "dust of the flower" is therefore of far more interest to the horticulturist than this old popular name would imply. Studies in hybridization and self-sterility have long made evident the practical importance of a knowledge of pollen. Every plant provides for the production of this material, and usually in definite pollen-bearing parts termed stamens. The stamens are organs of the flower, and as essential as the carpels. The pollen is produced in definite sacs or compartments of the anther, comprising the tip of the stamens; and when the pollen is ripe, or mature, the fine grains are set free in quantity by the rupture of the inclosing sacs. The abundance of pollen produced may suggest wasteful management of the plant's resources, but a liberal supply of this substance is necessary. Although it requires but a single one of the small grains to fertilize a single ovule and produce a seed, pollen-grains are produced often a thousandfold more abundantly than ovules. The best offspring are usually produced when cross-fertilization occurs, and in the transfer of pollen from plant to plant it

is only a small part which can reach its destination. There are many chances and such great losses that abundance of pollen is a necessary provision.

3095. Pollen-grains of *Browallia*. (Magnified)

3096. Oddly marked pollen-grain of *Schaueria flavicomma*. (Magnified)

In general, flowers are pollinated by the wind and by insects; that is, pollen is transported by these two agencies. Flowers principally dependent upon the wind for pollination are termed anemophilous, while those visited by insects are designated entomophilous. These distinguishing terms may also be applied to the pollen itself. Anemophilous pollen is of a more or less spherical form, readily yielding to the wind, and correlated with this is a dry and inadherent outer surface. Such is the case, for example, in the various families to which the oak, willow, grasses, and pine belong, all of which plants are devoid of any stock of brilliant color or rich odors that might attract bug, moth, butterfly, or bee.

The pollen of the pine has even developed bladders, so as to be borne more lightly upon the wind. On the other hand, those plants largely dependent upon the visits of insects for pollination may have the pollen-grains provided with some kind of spines, ridges, furrows, or viscid coatings that they may the more readily adhere to hairy limbs or other surfaces of the insect which may come in contact with them. Here, then, is to be found a reason for the beauty and specialization of external wall. In entomophilous pollen the elliptical form of grain predominates, but the general shape is extremely various; and the plants producing such pollen are usually provided with beauty of flower, fragrance, or other insect attraction.

In order that the pollen which has been transported to the stigma may be effective, it must be healthy. Experiments have shown that weak and poorly nourished orchard trees often produce ineffective pollen. The nature of the season may also have much influence upon its character, continued rains causing great losses by preventing the maturity of this product as well as by mechanical injury and by precluding the winged carriers. Most plants have some special provision for the protection of the pollen against rain; that is, either by the closing of the flower under moist conditions, or by the location of the anthers in a sheltered tube, under projecting hairs, lobes, or other corolla appendages.

The individual particles of pollen are in the form of delicate grains only readily visible in some quantity, as in powdery masses. At the time when they are set free, the grains are generally entirely distinct from one another, to be blown about by an accidental wind or carried by visiting insects. In some cases, however, the grains are bound together loosely or by means of delicate glutinous threads (Rhododendron); they may be closely united in fours (heath family); or the whole tissue of an anther or its divisions may remain intact

3097. Pollen-grains of *Abutilon striatum* (above). Bedding geranium (*Pelargonium hortorum*, on right). *Chrysanthemum* (on lower left). (All magnified)

as pollinia (some orchids, milkweed, and others). A particular species of plant will produce pollen quite constant in form and attire; but an aggregation of cultivated varieties originated from a single species may show considerable variation in this regard. Nevertheless, form, size, color, surface markings, texture of wall, and translucency of contents are not fixed qualities even for related genera or species. See Figs. 3094–3097 for different forms of pollen.

When the healthy pollen of one plant falls upon the ripe stigma of a plant of the same species, the grains germinate in the sugary excretion of the stigma by the protrusion of a tube which penetrates the style and effects fertilization as described under *Fertilization* (Vol. III, page 1221). Furthermore, it is well known that while the flowers of many plants may be readily fertilized by their own pollen, the offspring are stronger when pollen from another plant or another variety has had access to the flower. Sometimes pollen from a foreign variety is absolutely essential to the best fruit-formation. This is particularly true of certain varieties of the pear. A poor quality of fruit can be prevented only by growing together different varieties. Again, although a plant may readily pollinate itself, yet the pollen from another plant or variety may be prepotent over its own. That is to say, if the plant be pollinated by its own pollen along with that of a foreign

variety, that of the foreign variety will usually effect fertilization. This can be explained only on physiological grounds, and at present merely from a theoretical point of view. Any pollen penetrates and effects fertilization because it is attracted, first by substances in the style, and later by the egg-cell itself. When a foreign variety is prepotent it is so because it is more readily attracted, due, we may say, to a greater difference of potential between the two elements, the two elements from the same plant being more in equilibrium and less markedly attractive. As regards pollen from a foreign species, it seems to be the rule that hybridization does not occur so readily, and we must then assume that the differences have become so great as to cause repulsion.

The detailed development of pollen is highly interesting and instructive on morphological grounds, but in this place a very brief account of the formation of the grains will suffice. The developmental phases in *Bignonia* (*Pyrostegia venusta*) will serve as an example. A cross-section of the young flower-bud will show that in the anther-sac regions, semicircular layers of large well-nourished cells (called archesporial cells) are differentiated. These cells divide and the layer increases in extent, yet in this case it is always only one cell in thickness. When these cells have finally attained considerable size and provided themselves with a thick wall, they divide more or less simultaneously; and then each of these daughter-cells divides again by a division following quickly upon the first. Each cell has then formed four new cells within its original walls. The new cells remain thus united in fours until each is provided with a stout wall of its own, and then they separate. Each cell is then an immature pollen-grain, and technically a spore, that is, exactly homologous with the microspores of the vascular cryptogams. As a rule, before these pollen-grains are set free, another change occurs denoting maturity. This consists in the division of the nucleus of the spore in such a way that two cells of unequal size result (in some conifers several small cells are formed). On germination the large cell, which now incloses the smaller, protrudes the tube which penetrates the style; whereas the nucleus of the small cell divides into two, and one of these fuses with the egg-cell in the ovule, thus fertilizing it.

B. M. DUGGAR.

Pollination.

In botanical usage, pollination is the transfer of pollen from the anther to the stigma. In horticultural usage, particularly with reference to orchard fruits, the term is often applied in a general way to designate all the influences concerned in the setting of fruit. For the benefit of those who are uninformed in botany it may be said that pollination is concerned primarily with the "essential organs" of the flower,—the stamens and pistils. The stamens bear the pollen in their anthers, and they die after the pollen is shed. The pistils bear the ovary or seed-case, the style, and the stigma. The pollen falls upon the stigma. In some plants these organs are separated in different flowers or even on different plants. (Fig. 3098.)

Aside from those cases in which the stamens and pistils are so intimately associated that the pollen falls directly upon the stigma, flowers are pollinated mainly in two ways: by wind and by insects. The grasses, sedges, and pines are examples of wind-pollinated plants. The flowers of wind-pollinated plants are usually inconspicuous and without nectar or fragrance. They produce a great abundance of light dry pollen, which is wafted away by the slightest breeze and is often carried many miles by a strong wind. The pistils of these plants are long and feathery, and thus are well adapted to catch flying pollen.

The flowers of insect-pollinated plants, on the other hand, are usually showy, and have nectar or fragrance,

or both. The pollen is more or less moist or sticky, so that it is not easily blown away. Insects are probably attracted by the showy colors and by the perfume, both of which bespeak the presence of nectar. As the insect reaches down for the nectar, which is near the bottom of the flower, some parts of its body are almost sure to become dusted with pollen. When the insect visits another flower some of this pollen may be brushed upon the stigma and a fresh supply received. This pollen likewise may be carried to another flower, and so on. Thus cross-pollination, or the transfer of pollen from the anthers of one flower to the pistil of another, is accomplished.

Many flowers, notably the orchids, have special modifications of structure apparently developed for the purpose of securing cross-pollination by insects and preventing self-pollination. The bodies of some insects, also, have corresponding adaptations which insure the cross-pollination of certain flowers which they are in the habit of visiting most frequently. This correlation between flowers and their insect visitors has been the subject of extended observation. "Fertilization of Flowers," by Herman Müller, contains a bibliography of the subject up to 1886. For the distinction between fertilization and pollination, see the article *Fertilization*, page 1221.

The value of crossing to plants was first clearly proved by Charles Darwin in 1859. From the observations of Kolreuter, Sprengel, Knight, and his own exhaustive experiments, Darwin showed that continued self-fertilization is likely to result in inferior offspring; while cross-fertilization, within certain limits, gives greater vigor to the offspring. Cross-fertilization between different flowers on the same plant usually has no appreciable advantage. The probable reason for this is that the plant resulting from the union of unlike parents, as in cross-fertilization between flowers on different plants, is more variable than one resulting from self-fertilization or crossing between different flowers on the same plant, and hence has a better chance of fitting into new conditions.

Plants are endlessly modified to secure cross-fertilization and avoid self-fertilization. The principal means by which this end is gained are: (1) Special contrivances in the structure of the flower which favor cross-pollination. (2) A difference in the time at which the pollen matures and the stigmas become receptive in the same flower (dichogamy). This condition is very noticeable in some varieties of orchard fruits. The prematurity of the pistil is more common than the prematurity of the stamens. (3) Self-sterility, which is the inability of a flower to set fruit with its own pollen. Self-sterility is not usually due to a deficiency of pollen or to defective pistils. The pollen-grains often germinate on the stigma, but fertilization does not take place. The embryological reasons for this are not clearly understood. The ultimate cause of self-sterility in the grape

3098. Structure of the flower, to illustrate pollination.

1. Top.—The structure of a plum blossom: *sc*, sepals; *p*, petals; *sta*, stamens; *a*, ovary; *s*, style; *st*, stigma. The pistil is composed of the ovary, style, and stigma. It contains the female part. The stamens are tipped with anthers in which the pollen, or male part, is borne. The ovary, *a*, ripens into the fruit.

2. Fuchsia, showing ovary at *a*, 3 stamens (one is removed) and the projecting style.

3. Buttercup, showing many small pistils in the center and stamens surrounding them.

4. Bottom.—Phlox, showing the 3-parted stigma, and the stamens included in the tube.

has been studied by Dorsey. Cytological studies of the pollen of self-sterile varieties showed distinct degenerative processes in the generative nucleus, or arrested development previous to mitosis in the microspore nucleus. Dorsey concludes that self-sterility in the grape is not due to hybridity alone, as suggested by Beach, since there are both fertile and sterile hybrid varieties; but is due also to deep-seated influences operating to produce declinism and dioeciousness, the native species of grapes being mostly dioecious. Dorsey finds the nuclei of the pollen of many self-sterile varieties of native plums to be degenerated and disorganized. Degeneration of the pollen cannot be the main cause of self-sterility, however, since two self-sterile varieties may be mutually fruitful when planted together. About sixty species of plants are known to be more or less self-sterile. (4) The separation of the sexes in different flowers or on different individuals. It is thought by some that there is a gradual evolution among some kinds of plants toward unisexuality, and that adaptations for insect-pollination, dichogamy, and self-sterility are steps in this process.

Self-sterility has an important economic aspect in the culture of certain fruits. It is common in varieties of pears, apples, plums, and grapes; it is uncommon or unknown in cherries, peaches, raspberries, currants, gooseberries, and strawberries. Whenever isolated trees or large blocks of a variety blossom full year after year, but drop most of the fruit before it is half-grown, the variety may be self-sterile, provided the failure cannot be attributed to excessive vegetative vigor, marked lack of vigor, disease (especially scab, brown-rot, and fire blight), insect attack, unfavorable weather during the blossoming season, or other untoward circumstance. Self-sterile varieties are detected experimentally by inclosing the unopened blossoms in thin paper sacks, and dusting the pistils, when receptive, with the pollen produced by these blossoms; or by emasculating them and hand-crossing with pollen of the same variety. If very few fruits are produced from a large number of these selfed blossoms, but the variety fruits abundantly when crossed with other sorts, it is self-sterile. A few varieties of fruits are more or less self-fruitful, as distinct from self-sterile; they bear good fruit with their own pollen, but the fruits are seedless, as in the banana. Ewert found that many apples in Germany have this parthenocarpic development; that is, they grow without fertilization. It is not common in North American varieties of fruits.

Self-sterility is not a constant factor in any variety. It appears to be almost as easily influenced by the conditions under which the plant is grown as is the shape or color of the fruit. A variety is frequently self-sterile in one locality and self-fertile in another. Waite found several varieties of Japanese plums self-sterile, but concluded, "With plums, as

with other fruits, self-sterility is purely relative; under favorable conditions these varieties are able to set fruit without cross-pollination." Powell proved that in different parts of the Delaware-Maryland peninsula the Kieffer pear is self-sterile, partially self-fertile, or completely self-fertile. The Ben Davis apple is self-sterile in Vermont, according to Waugh, but self-fertile in Kansas, in the experiments of Greene. Bartlett pear is self-sterile in most of the Atlantic States, but usually self-fertile on the Pacific Coast. Beach found that varieties of grapes which are weakly self-fertile vary in this respect in different localities, and even in different parts of the same vineyard, being entirely self-fertile in one place and completely self-sterile in another. It is quite evident that the degree of adaptation of a variety to its environment of soil and climate has much to do with its ability to fruit abundantly with its own pollen.

It is not possible, therefore, to give a list of varieties that are self-sterile, and another list of those that are self-fertile, that would have more than local application. There are certain sorts, however, that are less dependable in this respect than others. Out of eighty-seven varieties of apples tested in Oregon by Lewis, fifty-nine were self-sterile, fifteen self-fertile, and thirteen partially self-fertile. Powell found practically all the commercial varieties of apples in Delaware self-sterile, except several summer sorts. Some of the prominent commercial varieties that are usually more or less uncertain are: Arkansas (Mammoth Black Twig), Gravenstein, Grimes, Jonathan, King (of Tompkins), Limbertwig, Paragon, Northern Spy, Ortley, Rome, Spitzenburg (Esopus), Twenty Ounce, Winesap. Among those generally quite dependable are Ben Davis, Baldwin, Oldenburg, Rhode Island Greening, Yellow Transparent, Yellow Newtown.

Anjou, Bartlett, Claireau, Clapp, Howell, Kieffer, Lawrence, Nelis, and Sheldon pears are frequently uncertain, while Angouleme (Duchess), Bosc, Flemish, and Seckel are usually self-fertile. Practically all the varieties of Japanese and native plums are self-sterile, the single exception, according to Waugh, being Robinson. Wild Goose and Miner are notoriously infertile. Hooper and Backhouse report that the European varieties are largely self-sterile in England, but in America the defection is confined chiefly to Coe, French Prune, and Italian Prune. The experiments of Close, Whitten, and Howard, indicate that all the leading varieties of peaches are self-fertile, and are not benefited by cross-pollination. In Germany, however, Ewart finds peaches "sparingly self-sterile." No cherries are known to be self-sterile, although Napoleon, Belle de Choisy, and Reine Hortense have that reputation among commercial growers.

Of one hundred and forty-five varieties of grapes tested by Beach, thirty-one were self-fertile, forty-one self-sterile, and seventy-three uncertain. Brighton, Herbert, Lindley, Merrimac, Salem, Wilder, and other hybrid varieties are decidedly unfruitful with their own pollen; while Concord, Delaware, Diamond, Niagara, Winchell, and Worden are among those strongly self-fertile. Reimer found the Scuppernon and other varieties of the Muscadine grape so defective in pollen that they are fruitful only when planted near male vines of the Muscadine. No varieties of the quince, raspberry, currant, gooseberry, or strawberry have been found self-sterile, but many varieties of strawberries lack well-developed stamens and so must be planted near perfect-flowered sorts.

A self-sterile variety often may be made fruitful by planting near it another variety to supply pollen; or by top-grafting part of the tree with cions of another sort. No benefit is derived from other trees of the same variety, even if brought from a distance, since all are but divisions of the same original seedling. In the selection of a pollinizer, several points must be con-

sidered: (1) The two sorts must blossom approximately at the same time in order that cross-pollination may be possible. The transfer of pollen from one variety to another is performed mainly by insects. Waugh and Backhouse have shown that practically none of the pollen of the plum and other stone-fruits is carried by wind, it being moist and sticky. The same is true of pears, but apple pollen is somewhat drier and is wind-blown to a slight extent. The honey-bee is the most important pollen-carrier. Hooper estimates that in England 80 per cent of the cross-pollination is done by the hive bee, 15 per cent by various wild bees, especially the bumblebee, and 5 per cent by miscellaneous insects. In tree-fruits it is necessary to select varieties that come into bearing at about the same age, otherwise one might be without cross-pollination for the first two or three years. Several state experiment stations have published lists of varieties blossoming at the same time, for the guidance of the planter. See New York (Geneva) Bulletin No. 407. (2) There should be an affinity between the two varieties, so that the self-sterile sort may find the pollen of the other acceptable. This can be determined only by hand-crossing. Beach found that the pollen of self-sterile varieties of grapes is practically incapable of fertilizing other varieties; but this does not hold for tree-fruits since two self-sterile varieties planted together usually are mutually fruitful. Powell found no affinity between Paragon and Stayman apples; Kerr none between Wild Goose and Whitaker plums, and there are a number of other instances. Undoubtedly some varieties are more acceptable as pollinizers of a self-sterile variety than others. Spitzenburg apples produced by Lewis from Jonathan pollen averaged 144 grams in weight; from Baldwin pollen, 157 grams. In general, however, varieties of the same species that blossom simultaneously cross-fertilize readily, and there is no appreciable and constant difference in the fruit. (3) In commercial orchards the pollinizer should be a standard variety, valuable for market. (4) It should produce a large amount of pollen. Winesap produces little pollen; it would be unsatisfactory as a pollinizer for other sorts; Grimes, Ben Davis, and Rome are abundant pollen-bearers.

Cross-pollinated fruits may be larger and heavier than self-pollinated fruits, but there is rarely any other influence. The shape, color, flavor, and keeping quality remain the same, regardless of the variety selected as a pollinizer. Kieffer pears pollinated with Seckel look and taste no different from Kieffer pears pollinated with Le Conte. Many supposed instances of the immediate influence of pollen have been recorded, but in most cases proof is lacking that the changes were not due to bud-variation. It cannot be doubted that this influence is exerted occasionally, but certainly much less frequently than is commonly supposed.

In small orchards there is no need of mixing the varieties with special reference to cross-pollination. In orchards covering more than 10 acres, it is desirable to intersperse the varieties at regular intervals. It is more convenient in spraying, harvesting, and other orchard operations to plant the pollinizer in a solid row instead of mixing it in the rows with the self-sterile sort. If the pollinizer is not very valuable, one row in ten may be sufficient; but usually one in four to six is safer. If the pollinizer is a valuable variety, the two should be alternated in blocks of four to six rows each. It is not necessary to plant more than one variety as a pollinizer.

Orchard pollination, however, is a broader problem than the mere detection of varieties that are inclined to be unfruitful when planted alone, and discovering which are the best pollinizers for each of them. Experiments in crossing and observations in orchards indicate that nearly all varieties, whether self-sterile or self-fertile, will produce more or better fruit with foreign pollen than with their own. Powell found that some self-fertile trees of Kieffer in Delaware bore a light crop

with their own pollen, 4 per cent of the self-pollinated blossoms producing fruit; but bore a much heavier crop when pollinated with Duchess, Lawrence, and other varieties, 76 per cent of the crossed blossoms producing fruit. Yellow Newtown is distinctly self-fertile in Oregon, yet Lewis noted a decided improvement in the fruit when Jonathan and Grimes pollen was used upon it. He concluded, "All varieties of pome-fruits, at least of apples and pears, even though they may be termed self-fertile, are benefited by having other varieties planted with them as pollenizers." The benefit will usually more than offset the slight inconvenience in orchard management occasioned by this mixed planting. The chief economic problem for the experimenter, therefore, is to determine what commercial varieties may be planted together for best results; and the rational course for the fruit-grower is to practise mixed planting on the basis of these experiments.

Those who wish to study the subject of fruit-pollination in greater detail should consult the following publications: Vermont Experiment Station Reports, 1896-1900; Delaware Experiment Station Reports, 1900-1902; Oregon Experiment Station Bulletin No. 104, Circular No. 20, Research Bulletin No. 1; New York (Geneva) Experiment Station Reports, 1892-1895; Bulletins Nos. 153, 157, 169, 223; Wisconsin Experiment Station Reports, 1894-1896; New York (Cornell) Experiment Station Bulletin No. 181; North Carolina State Experiment Station Bulletins Nos. 201, 209; United States Department of Agriculture, Division of Vegetable Pathology, Bulletin No. 5; Minnesota Experiment Station Bulletin No. 144; Missouri Experiment Station Bulletin No. 117; Virginia Experiment Station Report 1909-1910.

S. W. FLETCHER.

PÓLLIA (named after van der Poll). *Commelinaceæ*. Perennial herbs: sts. ascending from a creeping base or often erect, sometimes stout: lvs. very large: infl. terminal panicles either lax thyrsoid, or short and dense; sepals 3, persistent; petals 3, small, obovate, white or pale rose; stamens 6 or 3 and 3 staminodes; ovary 3-celled, 2- to many-seeded: fr. a globose or ellipsoid indehiscent caps.—About 18 species in Afr., India, Malaya, E. Asia, the Philippines, and Austral. *P. condensata*, C. B. Clarke. Nearly glabrous: sts. 2-6 ft. long, thick: lvs. 12 x 3 in., lanceolate-obovate, acuminate at either end: panicle 20-40-fl., dense; stamens 3, fertile. Trop. Afr. Var. *variegata*, Hort., differs from the type in having the long dark green, oblong-lanceolate lvs. variegated with yellowish white. Trop. Afr. R.B. 34:407.—Grown for ornament.

POLYANTHUS. In common speech Polyanthus means the florists' flower supposed to be derived chiefly from *Primula elatior* or its allies. The "Polyanthus Narcissus" of trade catalogues is one of the forms of *Narcissus Tazetta*, an old synonym of which was *Narcissus Polyanthos*. Polyanthus may also mean the tuberose, Polianthes, which see. There is no genus known as Polyanthus.

POLYBÔTRYA (Greek, *many* and *grapes*; referring to the massed sporangia). *Polypodiaceæ*. A small group of tropical ferns somewhat related to Dryopteris, but characterized by having the sporangia massed and covering the entire under side of the fertile lvs. as in *Acrostichum*, to which the species have been referred: lvs. 1-4 times pinnate, the fertile lvs. reduced so in tissue that they consist of little more than lf.-skeletons, affording space for the production of the sporangia.

osmundacea, HBK. Rootstock wide, climbing, with long, linear scales: sterile lvs. 2-3 ft. long, the lower pinnæ 8-10 in. long, with numerous slightly stalked segms., veins free; fertile lvs. tripinnate, with the lower pinnæ 1-2 ft. long, 4-8 in. wide, with narrow, cylindric

segms. $\frac{1}{4}$ - $\frac{3}{4}$ in. long. W. Indies to Brazil.—Probably the handsomest of the climbing kinds. Another cult. species sometimes included in this genus is designated here *Olfersia cervina* (*Acrostichum cervinum*), which see.

R. C. BENEDICT.

POLYCALÝMMA: *Myriocephalus*.

POLYCÝCNIS (Greek, *many* and *swan*, probably referring to the lip and column which together bear some resemblance to a swan). *Orchidaceæ*. Epiphytic herbs with very short vaginate 1-lvd. sts., scarcely thickened to a fleshy pseudobulb: lf. broad, plicate-veined, contracted to the petiole: scapes erect from the rhizome, few-sheathed; fls. rather large, pedicelled; sepals subequal, free, spreading, narrow; petals similar to the sepals or at the base narrower and substipitate, labellum affixed to the base of the column, spreading, sometimes 2-aucled at the base, column elongated, slender: fr. a caps.—About 7 species in Trop. Amer. *P. Charlesworthii*, Hort. Infl. long and arching, bearing about 50 fls. which are 1 in. across; sepals broad, yellowish, closely mottled with pale red-brown, the upper abruptly turned back; petals linear, twisted, yellow, slightly marked with red at the base; lip long, narrow, brownish with whitish hairs. British Guiana. Intro. abroad and offered for sale there. The following species may have been cult.: *P. barbata*, Reichb. f. (*Cynoches barbatum*, Lindl.); *P. gratiösa*, Endres & Reichb. f.; *P. lepida*, Lind. & Reichb. f.; *P. muscifera*, Reichb. f. (*Cynoches musciferum*, Lindl. & Paxt.); and *P. vittata*, Reichb. f. (*Houlettia vittata*, Lindl.). Warmhouse plants.

F. TRACY HUBBARD.

POLÝGALA (Greek, *much milk*; from the old idea that some species increased the flow of milk). *Polygalaceæ*. MILKWORT. Annual or perennial herbs, subshrubs, shrubs or very seldom trees, sometimes planted in the open or some kinds raised under glass for the bloom.

Leaves alternate or rarely opposite or verticillate, with or without stipules: infl. racemes or spikes, terminal, lateral, or forked, rarely axillary; fls. showy or

3099. *Polygala paucifolia*. ($\times \frac{3}{4}$)

small, colors various; calyx with very dissimilar sepals, the lateral (inner) pair larger; petals rarely 5, usually reduced to 3; stamens 8; ovary 2-celled: fr. a compressed 2-celled wing-margined or wingless caps.—About 550 species scattered through the temperate and subtropical regions of the world and a few species in the tropics.

Polygalas from a cultural standpoint may be grouped as hardy and tender species and the latter are sometimes cultivated under glass, frequently outdoors in the South, as in southern California. There are about

forty North American species but only a few of them have been offered by dealers in native plants. The hardy species should be grown in rather light soil, but they require some moisture and are best adapted to partially shaded positions. They may be raised from seed sown in the fall or early spring. The more commonly cultivated species are the exotic ones, especially the shrubby Cape kinds which grow from 2 to 4 feet or more high, bearing subterminal racemes of large flowers.

A. Plants hardy.

B. Fls. showy, $\frac{1}{2}$ – $\frac{3}{4}$ in. long.

C. Keel beautifully fringed.

1. *paucifolia*, Willd. FLOWERING WINTERGREEN. GAYWINGS. FRINGED MILKWORT. FRINGED POLYGALA. Fig. 3099. Trailer, 3–6 in. high: upper lvs. clustered, ovate, $1\frac{1}{2}$ in. long; lower lvs. distant, small, and becoming mere bracts at the base: fls. bright rosy purple, varying to white, 1–4 in the axils of the upper lvs. or appearing terminal. May, June. New Brunswick, and Ga. Prefers moist woods and sphagnum bogs. B.M. 2852 (petals white). B.B. 2:361. Var. *alba* was once offered by a Mass. dealer in hardy plants, where it grows wild. One sometimes finds violet-flid. forms. The species bears cleistogamous fls.

cc. Keel merely 4-lobed.

2. *Chamaebuxus*, Linn. BOX-LEAVED MILKWORT. Evergreen trailer: upper lvs. lanceolate or elliptical, mucronate; lower lvs. smaller, obovate: peduncles axillary and terminal, about 2-flid.; fls. as many as 10 on a stalk, typically yellow, more or less reddish toward the end of the keel; stamens united only at the base. April–June. Eu., low heaths and woods to highest Alps. L.B. C. 6:593. B.M. 316 (wings white; petals white at base, yellow or red at tip). Var. *grandiflora*, Gaudin (var. *purpurea*, Neill.), has purple wings, set off by yellow petals. Gn. 13:36; 30: 148 (charming: wings rosy pink).

BB. Fls. not showy.

c. Infl. a spike; fls. not pedicelled.

3. *Séne*, Linn. SENECA SNAKE-ROOT. MOUNTAIN FLAX. Fig. 3100. Height 1 ft. or less: lvs. 1–2 in. long: fls. white or greenish, $1\frac{1}{2}$ lines long; crest small, few-lobed. May, June. Rocky woods, New Brunswick, to Rockies, south to N. C. to Mo. B.B. 2:360. L.B.C. 14:1380. B.M. 1051. —Bears no underground fls. Root used in medicine.

3100. *Polygala Senega*. ($\times \frac{1}{4}$)

cc. Infl. a raceme; fls. pedicelled.

4. *polygama*, Walt. Height 1 ft. or less: lvs. 1 in. or less long: fls. purple or rose, rarely nearly white, 2–3 lines long; crest relatively large, lacinate. June, July. Dry soil, Nova Scotia to Lake of the Woods, S. Fla. to Texas. B.B. 2:360.—Bears numerous underground fls.

AA. Plants tender.

B. Habit shrubby, erect, 2–3 ft. high or more.

C. Lvs. opposite.

5. *oppositifolia*, Linn. Probably the only species in the genus with opposite lvs.; an abnormal feature in the whole family. Tall slender shrub: racemes few-flid.; fls. large, purplish. S. Afr. B.M. 492. B.R. 636.—Harvey gives 8 botanical varieties, of which probably the commonest in cult. is var. *cordata*, Harv. (*P. cordifolia*, Thunb., not Presl. *P. oppositifolia* var. *major*, Lindl. *P. oppositifolia cordifolia*, Voss). Glabrous or downy: lvs. broadly cordate, acute or acuminate: fls. bright purple-red or purple-violet. B.M. 2438. B.R. 1146. L.B.C. 12:1189. Var. *latifolia*, Ker (*P. grandis*, Hort.). Lvs. heart-shaped, acute, smooth: fls. large, beautiful purple-violet, bearded.

cc. Lvs. alternate.

d. Lateral petals 2-cut.

6. *myrtifolia*, Linn. Readily told from *P. virgata*, its infl. being a few-flid., leafy raceme, while that of *P. virgata* is many-flid. and leafless. Densely branched shrub, 3–8 ft. high, with large, showy fls. near the ends of the branches: lvs. flat, variable in shape, but not subulate: lateral petals 2-lobed, the posterior lobe ear-shaped, reflexed. S. Afr. Var. *grandiflora*, Hook. (*P. grandiflora*, Hort., and L.B.C. 13:1227, not Walt. *P. longiflora*, Dietr.). Fls. over 1 in. long. B.M. 3616. B.R. 669. G.W. 10, p. 629.

7. *Dalmaisia*, Hort. (*P. myrtifolia* var. *Dalmaisia*, Hort.), also often wrongly offered in the trade as *P. dalmacina* and *P. dalmatiana*. It resembles *P. myrtifolia* var. *grandiflora* very closely: lvs. rather tending to be alternate, sessile, rather glaucous as in *P. myrtifolia*: fls. in terminal racemes, rather large, purple or rosy magenta with the base of the keel whitened or almost white. R.H. 1844:193. Gt. 5:161. R.B. 25: 145. G.W. 8, p. 316.—*P. Dalmaisia* is said to be a hybrid *P. myrtifolia* var. *grandiflora* (*P. grandiflora*) crossed by *P. oppositifolia* var. *cordata* (*P. cordifolia*). The pictures show some slight verification of this, but many authorities treat the plant as a variety of *P. myrtifolia*; this species and its varieties are very commonly cult. in Calif., particularly the one known in gardens as *P. dalmacina* or *P. dalmatiana*; this flowers all the time and is very popular. The popularity of *P. Dalmaisia* in Calif. is an example of the persistence of a good thing in gardens, though almost unknown to botanists. The spelling *dalmatiana* shows that some gardeners have thought the name a geographical one. The plant was named after M. Dalmais, a French gardener, who raised it from seed in 1839. As known in the trade, *P. Dalmaisia* is a free-blooming plant with rosy or purplish fls. It goes under three or four names. It makes a good pot-plant, but is somewhat bare of foliage. It blooms from the ends of the ripened growth. It can be had in flower almost any time. The odd color and shape of the fls., and its free blooming, make it very attractive. It roots only fairly well from cuttings. Usually it propagates better by layering. Put in rich loam with well-rotted manure. It will stand considerable frost.

DD. Lateral petals not 2-cut.

8. *virgata*, Thunb. Glabrous shrub, 2–5 or even 15 ft. high, with rod-like branches terminating in many-flid., leafless racemes of purple or flesh-colored fls.: anterior sepals distinct; wings obtuse. S. Afr.—The

typical form is advertised in S. Calif., but in Eu. probably the only form cult. is var. *speciosa*, Harv. (*P. speciosa*, Sims). Glabrous: lower lvs. obovate or cuneate, upper more linear, all obtuse: raceme long and lax: bracts soon deciduous. S. Afr. B.M. 1780. L.B.C. 7:621. B.R. 150. B. 1:43.

9. *apopétala*, T. S. Brandeg. Frutescent, 2-3 ft. high: branches slender, pubescent: lvs. lanceolate, entire, obtuse, alternate, remote, short-petioled, nearly glabrous: fls. large, pink, on slender pedicels $\frac{1}{2}$ in. or more long; sepals 4, the upper and lower small, equal, cymbiform, margins ciliate, the lateral very large, nearly orbicular; petals 5, separate, upper strap-shaped, two-thirds as long as keel, lateral pointed, less than one-half as long, embraced with the 8 stamens by the large cymbiform keel, which is opened on the upper and lower edge and not cristate, or appendaged: seeds 2, large, ovoid, pubescent. Low. Calif. B.M. 8065.—In S. Calif. *P. apopetala* is said to grow up to 15 ft. or more in height and to be valuable economically as its young branches contain a very strong fiber and the pea-sized brown seeds which are plentifully produced yield as much as 38 per cent of excellent oil. The root has the same properties in a higher percentage as are contained in *P. Senega*.

BB. *Habit dwarf, 1 ft. or less high.*

10. *amatymbica*, Eckl. & Zeyn. (*P. acuminata*, E. Mey. & Hort.?, not Willd.). Densely tufted, erect, 3-6 in. high: lvs. lanceolate-acuminate, pungently mucronate: racemes lateral, few-fl'd., spreading or reflexed; fls. small, wings green, keel and petals flesh-color to purple; keel with a many-parted crest. S. Afr.—*P. acuminata* of the trade is probably not *P. acuminata*, Willd., which is *Badiera acuminata*. *Badiera* differs from *Polygala* in having 2 of the sepals only a little larger than the others, instead of much larger.

Two other species have been recently intro. into cult.: *P. brachypoda*, Tod., whose native country is not known, has erect growth, green very straight branches, long and very narrow lvs., and numerous reddish purple fls. Intro. into Calif.—*P. Vayredæ*, Costa. A small plant 4 in. high, hardy or half-hardy in England, growing only a few inches high, with linear, evergreen lvs. and reddish purple fls. with a yellow keel. Spain. Closely resembles *P. Chamæbuxus*, but has narrower lvs.

WILHELM MILLER.

F. TRACY HUBBARD.†

POLYGONATUM (Greek, *many knee*; alluding to the numerous joints of the rootstock). *Liliacæ*. SOLOMON'S SEAL. Perennial herbs, with simple stems from creeping knotted rootstocks, sometimes planted.

Stems naked below, above bearing nearly sessile or half-clasping nerved lvs. and axillary nodding greenish fls.: perianth cylindrical, 6-lobed at the summit; stamens 6; ovary 3-celled with 2-6 ovules in each cell: berry globular, black or blue.—About 60 species, widely distributed in the temperate regions of the northern hemisphere. The genus is distinguished from its nearest allies by the cylindrical perianth-tube with short lobes and small undivided style. *Polygonatum*s are graceful in their habit, the unbranched arching sts. bearing pendulous, tubular fls. 1-10 in the axils. The name Solomon's seal is connected with the horizontal rootstocks which are scarred by the death of the annual stems, each scar being likened to a seal (see *Smilacina*).

*Polygonatum*s are best suited for partially or wholly shaded positions, although they do well in the open in a well-prepared border. They like a deep rich soil not subject to drought. Easily propagated by division. They are among the best subjects for wild gardening. *P. multiflorum* is used abroad considerably for forcing and for house plants. Our native species are presumably equally desirable for all purposes. The Solomon's seal of English literature is *P. multiflorum*, which is probably the commonest species native to Europe. There are several Himalayan and Japanese species. The common Solomon's seal of our nurseries is the European, *P. multiflorum*, the American kinds being listed only by

specialists in native plants. The others here described are offered by Dutch bulb-growers. For extended articles on the forcing of *P. multiflorum*, see Gn. 26, p. 236 (or V. 7:337); 30, p. 49, and F.R. 3:594.

A. *Lvs. all whorled.*

verticillatum, All. St. 2-3 ft. high: lvs. in whorls of 4-8, linear, 3-6 in. long: fls. in 2's or 3's. Eu., Himalayas.—*P. macrophyllum*, Link, is perhaps a distinct variety with more robust habit and larger lvs.

AA. *Lvs. alternate.*

B. *Perianth 2-3 lines thick.*

officinale, All. Height 1-1½ ft.: fls. 1 or 2 in the axils: lvs. oblong, 2-3 in. long, firmer than those of *P. multiflorum*: perianth-segms. greenish. Eu., Siberia.—*P. ambiguum*, Link, is offered as a distinct form abroad.

latifolium, Desf. (*P. Thünbergii*, C. Morr.). Height 2-4 ft.: fls. 1-5 in the axils: lvs. oblong, 3-6 in. long: perianth-segm. greenish. Eu., Asia.—Intermediate in habit between *P. officinale* and *P. multiflorum*, but with earlier fls.

BB. *Perianth 1½-2 lines thick.*

C. *Plant glabrous.*

multiflorum, All. Height 2-3 ft.: lvs. oblong, 3-6 in. long: perianth-tube white; segms. greenish; filaments densely pilose. Eu., N. Asia, Himalayas. Gn. 26, p. 236; 30, p. 49; 69, p. 172. V. 7:337. Var. *flôre-rôseo*, Hort., has rosy fls.—There are said to be varieties with double fls. and variegated foliage. The type seems to be more graceful than the varieties. This is the common Solomon's seal of Eu., where it is also called lady's seal and David's harp.

commutatum, Dietr. (*P. giganteum*, Dietr.). Taller and more robust than *P. biflorum*, 1-8 ft. high: lvs. 1½-6 in. long, 3-4 in. wide: fls. 1-8 in the axils; filaments somewhat flattened, smooth, not roughened.

May-July. Moist woods, N. H. to Man., S. Ga., La. to New Mex. and Utah.

cc. *Plant with lvs. pubescent beneath.*

biflorum, Ell. Fig. 3101. Height 8 in. to 3 ft.: lvs. 2-4 in. long, $\frac{1}{2}$ -2 in. wide: fls. often 2 in axils, sometimes 1-4. April-July. Woods, New Bruns. to Mich., south to Fla. Mn. 8:49.

P. intermedium as offered in the European trade is presumably *P. intermedium*, Dum., which is commonly considered nothing more than a form of *P. multiflorum*, All.—*P. macranthum* of foreign trade-lists is botanically unknown. The plant offered in the American trade as *P. majus* is not known botanically, but it is said to grow 3 ft. high and bear pendent creamy fls. in May and June.

WILHELM MILLER.

F. TRACY HUBBARD.†

POLYGONELLA (diminutive of Polygonum). *Polygonaceæ*. About 7 species of American plants closely allied to Polygonum and of no horticultural standing, although one or two names may appear in the trade. *P. polygama* was offered in Mass. in 1881, but it is probably not hardy N. The genus differs from Polygonum in having only the inner sepals erect and the calyx enlarged in fr., while in Polygonum all the sepals are erect and the calyx is not enlarged in fr.

polygama, Gray (*P. parvifolia*, Michx.). Diffuse shrub: lvs. wedge-shaped, vertical, those on sterile shoots imbricated: racemes $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long, very numerous, in an oblong or corymbose panicle; fls. white, yellowish or rose-color; filaments all alike; stigmas nearly sessile. Aug., Sept. Dry sandy soil, Fla. to N. C.

americana, Small (*P. ericoides*, Engelm. & Gray. *Gonopyrum americanum*, Fisch. & Mey.). Perennial, frutescent: lvs. linear, persisting: racemes dense, divergent; calyx white or pink; pedicels divergent, jointed below the middle: achene elliptic-oblong, chestnut-brown. Dry soil, Mo. to Texas, east to Ga. and Ala.

POLYGONUM (Greek for *many-jointed*). Including *Persicaria*, *Bistorta*, *Tovara*. *Polygonaceæ*. JOINTWEED. KNOTWEED. SMARTWEED. Erect or twining plants, grown for ornament, the flowers and foliage often attractive.

Mostly herbs, annual or perennial, with small fls. on jointed pedicels in racemes, spikes or heads (sometimes solitary): lvs. alternate, simple, jointed to an ocrea or sheath which clasps or surrounds the st. and may at length split and become indistinct: fls. apetalous; calyx gamosepalous, 4-6-parted; stamens 3-9, sometimes exserted; ovary 1-loculed, with 2-3-parted style or stigma (latter capitate), ripening into a triangular or lenticular achene.—The species are perhaps 200 (if the genus is held to include *Persicaria*), of very wide distribution from arctic to tropical countries, and they are of widely different habit, from small annuals, slender twiners, to subshrubs, and ranging in habitat from dry open lands to deep woods and watery swamps. The calyx is corolla-like, often large enough and with sufficient color to render the infl. showy. Polygonum is closely allied to Rumex, the docks; and also to Fagopyrum, the buckwheats. Rumex differs in uniformly having a 6-parted calyx, some of the lobes often bearing

3102. Common doorweed or knotweed.—*Polygonum aviculare*. (×1; the details enlarged.)

a grain-like tubercle on the back, the stigmas tufted. Fagopyrum differs in having an achene surpassing the calyx and in details of the embryo. Most polygonums are weedy plants, and only a very small proportion are of merit for cult. One of the commonest species is the doorweed (Fig. 3102), *Polygonum aviculare*. It is a

3103. *Polygonum baldschuanicum*. (Spray × $\frac{1}{6}$)

decumbent wiry small-lvd. annual or perennial, growing along walks and in other hard dry soil, where it makes a sod-like mat. The axillary fls. are very small, seldom seen by others than botanists. Other polygonums are the common smartweeds of swales and damp grounds. For monograph of native and intro. species, see Small, "Monograph of the North American species of the genus Polygonum," in Mem. Dept. Bot. Columbia College, 1895.

Most of the cultivated polygonums are hardy border plants, requiring no special skill or care. They are propagated by seed and division, chiefly the latter. The rhizomatous species, as those of the East Asian region, produce readily divisible plants. Some of the cultivated kinds are annual, as *P. orientale*, and this species is the only one that is known as a familiar flower-garden plant, although it is now little grown and the seed is difficult to secure in the trade. *P. sachalinense* is a robust coarse plant of some value where screening foliage is desired and to occupy intractable ground; it was once extravagantly advertised as a forage plant. *P. baldschuanicum* is an attractive and worthy climber, hardy in the northern states. *P. Sieboldii* is one of the best of the species for the back or bold border and is useful for forming single clumps when strong herbaceous foliage effects are desired. The other species are employed mostly in wild gardening or for similar effects. The amphibious kinds make interesting subjects for bog-gardens. The pink or red often curved spikes of the *Persicaria* group are sometimes very ornamental. The

Asian set, from elevations in the Himalayan region and eastward to China and Japan, comprises very interesting plants for rock-gardens and herbaries. The polygonums provide good autumn-blooming plants.

A. Habit twining.

1. *cilinode*, Michx. Slender somewhat downy climber, mostly perennial: lvs. cordate-ovate to ovate-lanceolate, more or less angular or halberd-shaped at base: st. bearing a ring of retrorse bristles at the base of each sheath (whence the specific name): fls. white, in loose-paniced racemes from the upper axils. Nova Scotia south and west. R.H. 1913, p. 149.—Sold as a cover-plant for rocks and as a denizen of shrub-masses.

2. *baldschuanicum*, Regel. Fig. 3103. Tall perennial climber becoming woody at the base: lvs. cordate-oval or hastate, acuminate, slender-petioled: fls. small but very numerous, in terminal erect or drooping panicles, mostly rose-colored; fruiting calyx small, 3-sided, at first whitish and then becoming rose-colored: achene shining black. Bokhara. B.M. 7544. R.H. 1900, p. 35. Gt. 52, p. 381. G.C. III. 21:17; 41:399. Gn. 55, p. 454; 70, p. 274; 71, p. 19; 79, p. 41. G.M. 50:310. G. 35:657. G.W. 4, p. 253; 15, p. 626. Gng. 5:181.—A very vigorous and decorative hardy plant, climbing 20 ft. high, and, under favorable conditions, producing a profusion of pinkish, or sometimes whitish bloom; hardy N., and worthy greater attention. It was first described by Regel in 1884; bears the name of the town or place Baldschuan.

3. *Aubertii*, Henry. Resembles *P. baldschuanicum*, but said to be inferior to it: climbing to 25 ft. and more, becoming woody at base: lvs. ovate-lanceolate, cordate, obtuse or very short-pointed, reddish bronze or pale green and when young red at the apex: fls. small, whitish, rose-colored or green, in slender axillary panicles 6–8 in. long. W. China, Thibet, discovered by P. Georges Aubert, missionary. R.H. 1907, pp. 82, 83.—Said to grow with great rapidity, and to cover a large space; blooms in spring and again in autumn.

AA. Habit erect, or at least not climbing.

B. Plants annual, of erect habit, to be treated as flower-garden subjects.

4. *orientale*, Linn. (*Persicaria orientalis*, Spach). PRINCE'S FEATHER. Fig. 3104. Tall-growing annual, much branched above, hairy: lvs. large, ovate or cordate-ovate or broad-oblong, acuminate; sheaths short, ciliate and sometimes bordered at the summit: fls. bright pink, in close, cylindrical spikes that are arranged in open panicles, the stamens 7 and the achene lenticular. India. B.M. 213. J.H. III. 51:305. G.W. 6, p. 148.—An attractive old-fashioned plant growing as high as the fence. It is most easy of cult.; in fact, it usually self-sows in old gardens. In some places it has run wild. There are horticultural varieties, as var. *variegatum*, Hort., with foliage marked with yellowish white, and var. *pumilum*, Hort., with compact habit and the stature half that of the type.

5. *Persicaria*, Linn. LADY'S THUMB. One of the annual smartweeds, but sold by seedsmen as a suit-

able plant for backgrounds: glabrous or nearly so, erect or somewhat diffuse, 1–2 ft. tall: lvs. lanceolate to linear-lanceolate, slightly ciliate, usually with a triangular or crescent-shaped spot near the middle of the blade (whence the name lady's thumb); sheaths short, hairy on the margin: fls. in short spikes, pink or greenish purple, the stamens 6 and the achene lenticular or triquetrous. Eu.—Naturalized everywhere about dwellings.

6. *arenarium*, Waldst. & Kit. (*P. elegans*, Ten.). Dwarf annual species with slender wiry branches and long internodes: lvs. small, linear-lanceolate, 1-nerved, bearing great numbers of little whitish fls. along the st., the terminal clusters leafless. S. Eu.—Offered in Calif. for rockeries and bouquets.

BB. Plants perennial, of various habit, usually with strong rootstocks, sometimes shrubby.

C. Species native: smartweed-like plants, sometimes offered for naturalizing in bog-gardens.

7. *amphibium*, Linn. (*Persicaria amphibia*, S. F. Gray). Much spreading and creeping, rooting at the joints, at first more or less pubescent but becoming glabrous with age: lvs. rather thickish and large, oblong, elliptic or lance-elliptic, mostly obtuse or very nearly so; sheaths short, usually not fringed or bordered at the summit: fls. light rose-colored, in a short, dense, terminal spike, the stamens 5 and exserted, and the achene lenticular. In water or bogs, across the continent, and useful for planting in similar places.—When growing in water, the floating lvs. become long-petioled. Var. *Hartwrightii*, Bissell (*P. Hartwrightii*, Gray). Differs from the last in having many narrow-lanceolate lvs., bordered and fringed sheaths, and hispid sts., but the distinguishing mark is the foliaceous border on the sheath. Muddy places, across the continent.

CC. Species exotic, used mostly for borders, and appearing regularly in the trade, largely Himalayan and E. Asian.

D. Whole plant white-woolly.

8. *lanigerum*, R. Br. Sts. thick, creeping at the base, but the tops erect and standing 2–5 ft. high, much branched: lvs. narrow-lanceolate and more or less

recurved, acuminate, covered with down of the color of old silver; sheaths short, not ciliate: fls. small, red or copper-colored (varying to white), in racemes on slender forking peduncles, the stamens 6, and the achene flat and shining black. Tropics and subtropics of Old World and, according to Hooker, of Amer. R.H. 1891, p. 567. Gn. 62, p. 345; 70, p. 167. G.W. 2, p. 419; 13, p. 390.—Perennial and not hardy in the N., but seeds sown early will produce excellent lawn specimens, which are interesting because of the gray foliage and leafy habit.

DD. *Whole plant green or grayish, not white-woolly.*

E. *Fls. greenish or whitish, in very slender and long interrupted flexuose or curving wand-like spikes.*

9. *filifórmé*, Thunb. Perennial, mostly somewhat hispid, 2–5 ft., with hollow branches: lvs. petioled, pubescent, ovate or oval, short-acuminate: fls. very small, whitish (or rose-colored?), remotely placed in

3105. *Polygonum Sieboldii* (*P. cuspidatum*).
($\times \frac{1}{2}$)

spikes 5–8 in. or more long. Japan.—By some authors thought to be con-specific with the widespread *P. virginianum*, but lvs. less acuminate, bracts shorter-ciliate, fls. and frs. much smaller. Var. *variegátum*, Hort., has lvs. marbled with yellow and pale green: an attractive plant, forming good clumps $1\frac{1}{2}$ ft. high and persisting when well established. R.H. 1912, p. 259.

EE. *Fls. pink or red (sometimes varying to white), in erect usually simple stout spikes: plants grown for their fls.*

10. *Bistórta*, Linn. (*Bistórta officinális*, Raf.). BISTORT. SNAKEWEED. Perennial, with a thick more or less spreading rootstock: st. simple, slender but strict, 1–2 ft.: lvs. mostly radical, oblong-ovate and obtuse, undulate, glaucous beneath; st.-lvs. nearly sessile, broad at base; stipules $\frac{1}{2}$ –3 in. long: fls. white or pink, in a single dense cylindrical or oblong spike an inch or two

long; stamens exserted; styles 3. N. Eu. and N. Asia.—The astringent rootstock was once used medicinally, and has provided food in famine times. Var. *superbum*, Hort., is offered abroad, with conical heads of bright pink long-lasting fls.

11. *plexicaúle*, Don (*P. oxyphyllum*, Wall. *P. multiflorum*, Hort.). MOUNTAIN FLEECE. Strong-growing tufted green-stemmed perennial with slender fl.-sts. 2–3 ft. tall, from a woody branching rootstock: lvs. cordate-ovate to cordate-lanceolate, short-petioled or clasping, the margin wavy and crenulate, long-acuminate; sheaths 1–2 in. long and split or lacerate: fls. rose-red or white, rather large (sometimes $\frac{1}{4}$ in. diam.) in strict long-peduncled spikes 2–6 in. long, the stamens 8 and exserted, the achene trigonous. Himalaya, from 6,000–13,000 ft. altitude. B.R. 25:46. B.M. 6500.—An excellent border perennial, blooming in mid-summer. Some, at least, of the plants that have been cult. as mountain fleece are a native polygonum (*P. Muhlenbergii*), which grows nearly throughout N. Amer., including Mex. Var. *speciosum*, Hook. f. (*P. speciosum*, Wall.), has larger deep purplish red or claret-colored fls.

12. *affine*, Don (*P. Brundisii*, Wall.). Tufted glabrous perennial, with flowering sts. $1\frac{1}{2}$ ft. or less high, from a woody prostrate rootstock: lvs. mostly radical, oblanceolate to spatulate to lance-oblong; sheaths rather long, brown, split or entire: fls. bright rose-red, in dense, erect, terminal obtuse spikes 2–3 in. long, the stamens 8, the achene trigonous. Himalaya, at elevations of 9,000–14,000 ft. B.M. 6472.—An excellent little plant for cool places, blooming in autumn.

13. *vaccinifolium*, Wall. Tufted glabrous perennial with trailing and creeping branches, 1 ft. or less tall, and stout twisted rootstocks: fl.-branches leafy: lvs. small ($\frac{1}{2}$ – $\frac{2}{3}$ in. long), short-stalked, orbicular or elliptic, acute or acuminate, entire, somewhat glaucous beneath; stipules to $\frac{1}{2}$ in. long, brown, lacinate: fls. rose-red, $\frac{1}{4}$ in. diam., in subsessile racemes 2–3 in. long. Himalaya region, 9,000–14,000 and more ft. altitude. B.M. 4622. Gn. 39, p. 543; 43, p. 501; 45, p. 159. G.W. 9, p. 377. J.F. 2:117.

14. *Posumbu*, Hamilt. Dwarf compact perennial, with long-creeping st. which is ascendent or decumbent and simple or branched: lvs. dark green and shining, 1–3 in. long, stalked, broad-lanceolate and narrow-acuminate, glabrous or somewhat hairy, ciliate; stipules with stiff hairs longer than the sheath: fls. small, rose-colored, in many erect filiform racemes or spikes that are sometimes several inches long. Himalaya and to China and Japan.

EEE. *Fls. white to purplish, in paniced or corymbose heads.*

15. *chinénse*, Linn. (*P. cymosum*, Roxbg. *P. polycephalum*, Wall. *P. corymbosum*, Willd.). Shrubby perennial of diffuse or erect habit, 5 ft. high, from glabrous to glandular-pubescent, the many sts. angled and grooved: lvs. 3–5 in. long, stalked, variable in shape, from linear-oblong to deltoid, ovate or even broader, entire or crenulate, the petiole usually 2-eared at base; stipules long and oblique at top: fls. white, rose-color or purplish, borne in many little heads that are paniced or corymbose with usually glandular-hairy peduncles; perianth 5-cleft; stamens 8. Himalaya region and Ceylon to China, Japan, and the Philippines.

EEEE. *Fls. white or greenish, in axillary clustered racemes or panicles or cymes: plants grown often for their general foliage effects and bold habit, mostly tall and sometimes woody. (More or less diœcious or polygamous.)*

F. *Lvs. mostly on the lanceolate order, sometimes ovate, usually taper-based.*

16. *polystachyum*, Wall. Shrubby, glabrous, or pubescent perennial, 3–6 ft., the branches grooved: lvs.

petioled or nearly sessile, oblong-lanceolate, narrow-acuminate, usually contracted and more or less cordate or truncate at base; fls. white or pink, $\frac{1}{4}$ in. diam., in large thyrs-like spreading terminal panicles with branches erect or decurved and very slender pedicels; 2 outer sepals much smaller than the inner. Himalaya, 7,000–14,000 ft. altitude; Afghanistan. G.C. III. 53, suppl. May 17. G.M. 52:929. M.D.G. 1896:373, 385.—An excellent plant for late autumn bloom, in moist places.

17. *lichiangense*, W. W. Smith. Closely allied to *P. polystachyum*, but branches and stipules setose, lvs. setose above and densely cinereo-tomentose beneath: erect, with a woody base, 2–4 ft., the branches striate: lvs. very short-petioled, 2–5 in. long, lanceolate or oblong-lanceolate, caudate-acuminate, the margin more or less undulate; stipules about 1 in. long; fls. creamy white, in thyrsoide-paniculate clusters at nearly every node, the pedicels slender and about 1 line long. Lichiang Range, China, 10,000–11,000 ft. altitude.—A recent intro., with fl.-sprays said to resemble those of *P. baldschuanicum*.

18. *campanulatum*, Hook f. Pubescent or tomentose perennial, the sts. creeping or stoloniferous at base, forking above, 2–3 ft.: lvs. stalked, 3–6 in. long, elliptic, lanceolate or ovate, acuminate, the base narrow or rounded, more or less pubescent above and below; stipules large, mostly deciduous: fls. pale pink or red in autumn, in divaricately branched nodding or drooping terminal clusters; perianth campanulate, $\frac{1}{2}$ in. long or somewhat larger; stamens 8, with very long filaments. Himalayan region. G.C. III. 52:489.—Variable.

FF. Lvs. much wider, on the oval or broad-oval order, usually (or at least the lower ones) very broad-based.

19. *Sieboldii*, De Vriese (*P. cuspidatum*, Sieb. & Zucc., not Willd. *P. Zuccarinii*, Small). Fig. 3105. Strong stout handsome bushy somewhat woody perennial (stalks dying to the ground in winter), growing 4–8 ft. high, the sts. gracefully curving outward: lvs. short-oval to orbicular-ovate, truncate or slightly cordate at base, abruptly pointed, the strong side nerves uniting in marginal loops; sheaths short and flaring, deciduous: fls. small and whitish, very numerous, in drooping slender-panicled racemes, the stamens 8, and the achenes trigonous. Japan. B.M. 6503. R.H. 1858, p. 631; 1894, p. 54. Gn. 26, p. 317; 49, p. 238. G. 3:143. G.M. 47:861. G.W. 2, p. 76.—A very effective plant for bold mass effects, perfectly hardy in the northern states, and now frequently planted. It is everywhere known in the trade as *P. cuspidatum*. It produces clouds of bloom. Var. *compactum*, Hort. (*P. compactum*, Hook f.), is of very compact habit, remaining sometimes only 2 ft. high, bearing many erect panicles of whitish fls.: a good subject. B.M. 6476. G.C. III. 47:123. Gn. 63, p. 56. Gn.W. 20:926. Var. *spectabile*, Hort. (*P. cuspidatum* var. *spectabile*, de Norder). Shrubby, 3–5 ft.: lvs. marbled with green, white, and red. R.B. 35, p. 233.

20. *Weyrichii*, F. Schmidt. Tall herb (3 ft.): sts. hispid, in the upper part tomentose: sheaths elongated, membranous, pilose, finally fissured and falling off: lvs. short-petioled, ovate, acuminate, dull green and rugose above, whitish tomentose beneath, to 7 in. long, the lower ones broader and truncate at the base, the upper ones attenuate at the base, revolute at the margin: racemes axillary and terminal, forming a large terminal panicle; rachis fulvo-tomentose; pedicels articulate about the middle; bracts hyaline, glabrous, 2-lobed, 3–6-fld.; stamens 8; achenes 3-angled. Saghalin.—A good hardy perennial for moist ground.

21. *sachalinense*, F. Schmidt. SACALINE. Fig. 3106. Exceedingly vigorous plant, spreading rapidly from the tips of strong underground shoots, the reddish glabrous dead stalks often standing 8–12 ft. high through

the winter: lvs. very large, frequently 1 ft. or more long, soft dull green, the blade oval-oblong, $1\frac{1}{2}$ –2 times as long as broad, shallow-cordate at base, scarcely pointed, the prominent side veins uniting by the ends: fls. greenish, in relatively small axillary clusters, the achene trigonous. Isl. of Sachalin, north of Japan, in Russian territory. B.M. 6540. R.H. 1876, p. 36; 1893, pp. 394, 395; 1894, p. 55. Gn. 21, p. 280; 62, p. 439. G. 5:311. G.C. II. 26:813 and III. 14:159 (in fr.). G.M. 31:176. V. 17:161.—Recently intro. (in N. Amer. in 1894) for forage and for ornament. It is inveterately persistent when once established, and may easily become a pest. For forage it has little merit where other things can be grown, for it is too coarse. For planting in rough places, where a thick cover is

3106. *Polygonum sachalinense*. (× $\frac{1}{2}$)

required, it is one of the best of all coarse herbaceous perennials. It is perfectly hardy in the N. and seems to thrive anywhere. *P. Sieboldii* was once distributed as sachaline, but that species is much smaller, with smaller shorter and square-based lvs., and with more profuse bloom.

22. *Spaethii*, Damm. St. erect, 10 ft. and more, thick, minutely puberulent but becoming glabrous, the young growth densely pubescent or somewhat hirsute: lvs. petioled, cordate-ovate, acute or acuminate, the upper ones lanceolate, and attenuate at base, margin somewhat undulate and ciliate; sheath salver-shaped, densely pilose outside, the limb foliaceous, crenate and pilose: fls. in few-fld. paniculate spikes, short-pedicellate, carmine-red; stamens 5–6; achene lenticular. China.—Much like *P. sachalinense*, but differs in its fls., and the pubescence or hairiness.

P. crispulum, Sims= *Atraphaxis buxifolia*.—*P. cymosum*, Trev. (Fagopyrum cymosum, Meissn.). Puberulous perennial: lvs. triangular: fls. white, secund on long recurved branches of cymes. Himalaya to China.—*P. melle*, Don. Shrubby perennial, allied to *P. polystachyum*, the branches stout, terete and villous: lvs. elliptic-lanceolate, pubescent or tomentose beneath: fls. white, in large thyrses-like tomentose terminal panicles. Himalaya.—*P. multiflorum*, Thunb. Tuberous-rooted climber, with reddish sts.: lvs. cordate-ovate, acute, shining: fls. small and whitish, in spreading panicles. China and Japan.—*P. platycaulon*, Hort.= *Muehlenbeckia platyclada*.—*P. scandens*, Hort., as once described, is a twiner, with firm lvs., cordate at base, dark green above and claret-colored beneath. G.C. III. 28:187.—*P. sericeum*, Pall. Stout perennial, 4 ft., free-branching, with spirea-like panicles in July and Aug. of white fls.: densely pubescent: lvs. subsessile, oval-oblong, lanceolate, attenuate at base: fls. in short simple racemes terminal or in upper axils. Siberia.—*P. sphaerostachyum*, Meissn. Allied to *P. affine*, from which it differs in the "dense broad cylindric or globose spike of blood-red pendulous fls.": tufted perennial, suitable for small rock-gardens. Himalaya. B.M. 6847.

L. H. B.

POLYMNIA (the muse Polyhymnia). *Compositæ*. American composites, mostly coarse, viscid and heavy-scented.

The N. American species are tall branching perennials, with usually opposite thin lvs., and the S. American shrubby or tree-like. They have loose panicles of yellow or whitish fls. borne in summer. Heads broad, many-fl'd.; rays several, pistillate; disk-fls. perfect but sterile.—About 10 species.

canadensis, Linn. CANADA or SMALL-FLOWERED LEAF-CUP. Height 2-5 ft., the st. clammy-hairy: lvs. deltoid-ovate to hastate, thin, deeply angulate-lobed; lobes dentate, 4-10 in. long; heads few in terminal clusters, 4-6 lines broad; rays minute or none. June-Sept. Damp, rich, shaded places, Vt., Ont. to Minn., south to Ga. and Ark. B.B. 2:405. Var. *radiata*, Gray, with whitish rays sometimes $\frac{1}{2}$ in. long, is also offered by one dealer in native plants: st.-lvs. are more perfectly 3-lobed than in the type.

N. TAYLOR.†

POLYPODIUM (Greek, *many feet*; alluding to the extensive rootstocks). *Polypodiaceæ*. A large group of ferns, some hardy and some tender; the latter are often grown in under-glass collections.

Ferns with naked rounded sori, and with the lvs. jointed to the rootstocks, leaving a scar when they separate. As here treated the veins may be free or united to form areoles. The genus is a very extensive one, growing in all parts of the world, and has frequently been divided into a series of genera based on habit and the nature of venation, which is probably a more

3107. *Polypodium vulgare*. (×1/4)3108. Sori and a single sporangium of *Polypodium vulgare*. (Sori about natural size.)

logical treatment; some of these genera, indeed, as *Phymatodes* and *Phlebodium*, have here been separated; the genus would be more homogeneous were others placed by themselves. See comments in connection with *P. lingua* and *P. Phyllitidis*. For culture, see *Fern*.

subauriculatum, 10.
tricuspe, 13.
vacciniifolium, 5.
vulgare, 1.

A. Veins free: lvs. once pinnate.

B. Sori large, conspicuous.

1. *vulgare*, Linn. WALL FERN. POLYPODY. Figs. 3107, 3108. Lf.-blades 4-10 in. long, on pale stalks half their length, 1-3 in. wide, cut nearly or quite to the rachis into entire or slightly toothed blunt pinnæ. New England to Ala. and westward to Ore.; also common throughout Eu., where many forms are in cult.

3109. *Polypodium vacciniifolium*. (×1/2)

Var. *cambricum* (Fig. 3110) occurs in N. Y. and New England. Very many other varieties are cult. in England but unknown to American trade.

2. *falcatum*, Kellogg. Lvs. 12-15 in. long, 4-8 in. wide, on long, straw-colored stalks; pinnæ numerous, tapering to a slender point, sharply serrate. Calif. to Wash.

BB. Sori smaller.

3. *Plumula*, HBK. Lvs. 9-18 in. long, narrow-lanceolate, 1-2 in. wide; pinnæ numerous, narrow, entire, blunt, the lower pairs scarcely smaller than those above; stalks blackish. Fla. and Trop. Amer.

4. *pectinatum*, Linn. Lvs. elliptic-lanceolate, 1-2½ ft. long, 2-6 in. wide, cut to the rachis into horizontal entire or toothed pinnæ, the lower ones gradually reduced to short, triangular lobes. Fla. and Trop. Amer.

AA. Veins uniting, forming regular areoles each with a single free included veinlet.

B. Lvs. simple, undivided.

5. *vacciniifolium*, Langs. & Fisch. Fig. 3109. Lvs. small, of two sorts, rising from slender, wide-creeping rootstocks; sterile lvs. roundish or elliptic; sporophylls linear or ligulate, with large sori in a single row. Trop. Amer., from the W. Indies southward.

BB. Lvs. pinnate.

c. Fronds covered with flat scales underneath.

6. *polypodioides*, Hitchc. (*P. incanum*, Swartz). Lvs. 2-6 in. long, an inch or more wide, with entire pinnæ which are usually more or less revolute; veins indistinct, from the thick texture. Va. and S. Ill. to Brazil; commonly growing on trees in the southern states.—Known as resurrection fern from its ability to revive after long drying.

cc. Fronds smooth beneath.

D. Pinnæ broad at base and often confluent.

7. *californicum*, Kaulf. Lvs. 4-9 in. long, 1-5 in. wide, cut into finely toothed pinnæ which are mostly confluent at the base. Calif.—Has much the habit of the European forms of *P. vulgare*.

8. *Catharinæ*, Langs. & Fisch. Lvs. 6–12 in. long, 3–5 in. wide, with numerous nearly opposite pinnæ which are dilated at the base, contracted just above the base, and slightly enlarged and bluntly rounded at the tip; sori large near the midrib. Brazil.

DD. *Pinnæ narrowed and distinct at base.*

9. *fraxinifolium*, Jacq. Lvs. 2–4 ft. long, 12–18 in. wide, on firm stalks 1–2 ft. long; pinnæ 4–9 in. long, with a tough, somewhat leathery texture and entire margin. Columbia to Brazil and Peru.

10. *subauriculatum*, Blume. Stalks 6–12 in. long, glossy, from wide-creeping rootstocks: lf.-blades 2–3 ft. or more long, 8–12 in. wide; sori in a single row immersed in the leaf. India to Austral.

AAA. *Veins (primary) distinct from midrib to the edge, connected by parallel transverse veinlets forming rows of similar areoles.*

B. *Lvs. elongate, simple, smooth beneath.*

11. *Phyllitidis*, Linn. (*Campyloneuron Phyllitidis*, Presl). Lvs. 1–3 ft. long, 1–4 in. wide, with an acute point, and the lower part narrowed gradually; areoles in rows of 6–12, usually with 2 sori each. Fla. to Brazil.—This species might more justly be placed in the genus *Campyloneuron*.

BB. *Lvs. with under surface tomentose.*

12. *Lingua*, Swartz. Lf.-blades 4–8 in. long, 1–2 in. wide, the apex often cuspidate, the base narrowed or rounded; upper surface naked, the lower matted with reddish brown cottony scales, the sori in close rows of 4–6 each. Japan to Ceylon.—This species and the next are often more properly listed in the genus *Cyclophorus*. There are a few crested and other horticultural forms.

13. *tricuspis*, Swartz. Lvs. hastate, 2–4 in. each way, with a central lanceolate-triangular lobe and spreading lateral ones which are more or less auricled at the base. Japan and Korea.

P. aureum = *Phlebodium*.—*P. Dryopteris* = *Phegopteris Dryopteris*.—*P. glaucum* = *Phymatodes*.—*P. hexagonopterum* = *Phegopteris*.—*P. Kerandrium* = *Phegopteris*.—*P. lepidopteris*, Langs. & Fisch. (*P. sepultum*, Kaulf. *Lepicystis sepulta*) is a very scaly pinnatifid form from Trop. Amer., of some interest for collectors.—*P. musæfolium* = *Phymatodes*.—*P. nigræscens* = *Phymatodes*.—*P. Phegopteris* = *Phegopteris polypodioides*.—*P. Phymatodes* = *Phymatodes*.—*P. plumosum* is a form of *Asplenium Filix-femina*.—*P. quercifolium* = *Drynaria*.—*P. rigidulum* = *Drynaria*.—*P. Swartzii* = *Phymatodes*.

L. M. UNDERWOOD.

POLYPTERIS (Greek words meaning *many-winged* or *feathered*; referring to the pappus). *Compositæ*. This includes a handsome, rosy-flowered hardy annual known to the trade as *Palafoxia Hookeriana*.

Polypteris is a genus of 4 species of N. American herbs: lvs. mostly entire: alternate heads of pedunculate, rose-purple or flesh-colored fls. borne in summer and autumn: involucre broadly bell-shaped or top-shaped; bracts commonly in 2 series, more or less colored and petal-like toward the tips: rays wanting except in *P. Hookeriana*: achenes linear to club-shaped, 4-sided; pappus of 6–12 equal scales. Distinguished from *Palafoxia* by the colored tips of the involucre bracts and the deeply divided limb of the corolla. By some the genus is united with the older genus *Palafoxia*, which is also American.

Hookeriana, Gray (*Palafoxia Hookeriana*, Torr. & Gray). A stout annual 1–4 ft. high, sticky pubescent: lvs. lanceolate, mostly 3-nerved below: heads 1 in. or more across; rays 8–10, deeply 3-cleft, rose-red, about $\frac{1}{2}$ in. long and showy. Sandy plains, Neb. to Texas. B.M. 5549.—Handsome plant; sometimes treated as an everlasting.

N. TAYLOR.†

POLYRRHIZA (Greek, *many roots*). *Orchidacæ*. Epiphytes: sepals and petals spreading, labellum 3-lobed, lateral lobes small, angular, middle one with spreading lobes; spur long, filiform; column short; pollinia 2. The following are intro. into American horticulture:

Lindenii, Rolfe (*Dendrophylax Lindenii*). Scape leafless, bearing a single white fl.; sepals and petals lanceolate; divisions of midlobe of labellum lanceolate: caps. smooth. On *Oreodoxa Regia*, and live oaks, S. Fla.

funalis, Pfitz. (*Dendrophylax funalis*, Hort. *Ecoclades funalis*, Lindl. *Angræcum funale*, Lindl.). Leafless, roots numerous, fleshy: peduncles 2-fld.; fls. white; sepals and petals oblong-lanceolate; labellum 3-lobed, with a long horn. Mountains of Jamaica.

OAKES AMES.

GEORGE V. NASH.†

POLYSCIAS (*many and shade*; referring to the abundant foliage). *Araliacæ*. Large shrubs or trees, glabrous, comprising the pinnate-leaved tender aralias of greenhouses, grown for the ornamental foliage.

Leaves pinnate, with variable lfts., in many horticultural forms much cut, modified and often variegated: fls. very small, usually 5-merous (sometimes 4-merous), the calyx truncate or toothed, the petals valvate, the ovary 5–8-loculed; the styles usually of the same number and distinct.—About 70 species are described, from India, Trop. Afr., and Pacific Isls., some of which probably belong in other genera. Recent introductions from New Caledonia and other islands have given interesting forms for the cultivator. In cult. very rarely flowering; some specimens of *P. fruticosa* known to be 15 years old or more have never blossomed. From the temperate *Aralia*, comprising the Hercules' club, the genus is easily told by its lack of spines and also by the technical floral characters of little value to horticulturists, as the tender sorts rarely flower. From *Panax*, the ginseng, the genus is separated by its woody habit. From *Fatsia*, the true *Polyscias* is distinguished by having the pedicel usually articulated beneath the fl. The genus *Dizygotheca* is distinguished by digitate lvs. of many lfts., and 4-celled anthers and 10-celled ovary

3110. *Polypodium vulgare* var. *cambricum*. ($\times \frac{1}{2}$)

3111. *Aralia Chabrieri* of greenhouses, but properly an *Elæodendron*. ($\times \frac{1}{4}$)

(the allied genera have 2-celled anthers and mostly less than 10-celled ovary).

The glasshouse aralias are much confused botanically. The genus *Aralia* as understood by the older botanists turns out to be a polymorphous group, and in the segregation of other genera it is often difficult properly to redistribute the species. This is particularly true

of the cultivated forms, many of which are not only variable but the flowers and fruits may be unknown. Any arrangement of these forms must be considered to be tentative.

Four distinct types or forms of tender greenhouse aralias are illustrated herewith. Fig. 3111 is the *Aralia*

3112. *Dizygotheca elegantissima*. The *Aralia elegantissima* of greenhouses. ($\times \frac{1}{4}$)

Chabrieri of gardens. It has very long glossy stiffish long-pointed leaves with a dark red midrib, the margin entire or remotely denticulate and more or less revolute. These leaves are opposite or nearly so on short side branches, as if parts in a compound leaf, and apparently confusion has arisen in descriptions. In the illustration, a leaf is shown at *a*, in the axil of which is a branch bearing the leaves. This plant, which is cultivated in its juvenile state, has been little understood botanically. It is not an aralia nor of the aralia family, although referred doubtfully to *Polyscias*. It is now considered to be *Elæodendron orientale* (see page 1107, where the matter is left in doubt). Harms, an authority on these plants, has recently gone over the question (Gt. 62, pp. 533-5, and 63, p. 117), and has concluded that the plant is *E. orientale*. Guillaumin (R.H. 1912, p. 491) considers it to be an *Elæodendron* but not *E. orientale*. The long linear leaves with red mid-nerves are merely the young form of the species, and they pass into the broad-lanceolate or shorter oval or obovate thick leaves of the mature plant. *Aralia Chabrieri* apparently appeared first under this

name in 1881 in the catalogue of Van Geert, Ghent. For portraits of it, see R.B. 13:20 (1887); R.H. 1891, p. 224; Gn. 39, p. 576.

The florists' plant shown in Fig. 3112 is *Dizygotheca elegantissima*, Vig. & Guill. (*Aralia elegantissima*, Veitch). Very similar plants are *Aralia Veitchii*, Hort. Veitch, and its var. *gracillima*, Hort. Bull. (*A. gracillima*, Hort. A. *gracilina*, Lind. R.H. 1877, p. 38), its var. *robusta*, Hort., and *A. Kerchoveana*, Hort. It is not unlikely that all the plants mentioned above in this paragraph are foliar forms of one species, representing a juvenile state of a *Dizygotheca* (page 1062), although it is possible that other generic disposition will be made of these things when the different forms and the flowers and fruits are known. These names, as represented in plants in the trade, however, are of two groups: (1) *Aralia Veitchii*, *A. Veitchii robusta*, and *A. gracillima* with undulate nearly or quite entire leaflets, which may be tentatively called *Dizygotheca Veitchii*, Hort.; (2) the other group is *A. Kerchoveana* and *A. elegantissima*, with strongly notch-toothed leaflets, which are about 1 in. broad in the former and about half as wide in the latter; the former is *Dizygotheca Kerchoveana*, Hort., and the latter *D. elegantissima*, Vig. & Guill.

The plants shown in Figs. 3113 to 3117 are by some referred to *Nothopanax*; but until their position is better determined, they may be described tentatively under *Polyscias*. *Nothopanax* as understood by Harms has leaves primarily digitate whereas *Polyscias* has leaves on the pinnate order; as defined by others, however, *Nothopanax* comprises species with leaves simple, pinnate or pinnately decom-pound. As in many of the araliads, the leaves in this general group are very variable. Harms calls attention to the fact that in *Nothopanax* the leaves may be different on the same plant in successive ages. On the young plants the leaves are mostly digitate with the leaflets

3114. *Polyscias Guilfoylei*.

often once-pinnatisect; older plants have simple leaves and the leaflets entire or toothed or once-pinnatisect, or sometimes only digitate leaves.

The culture of the several kinds of plants known to florists and greenhouse men as aralias is not difficult. Among the most desirable tropical kinds, are, those known in the trade as *Aralia* (*Elæodendron*) *Chabrieri*, *A. elegantissima*, *A. Veitchii*, *A. gracillima*, *A. leptophylla* (all *Dizygotheca*), *A. monstrosa*, *A. Victorix*, *A. plumatum*, (all *Polyscias*) and others. Aralias are increased by cuttings and by grafts. *A. leptophylla*, and the forms of *A. Veitchii*, are rarely propagated except by grafting. The stock considered by many to be the best to use is *A. reticulata* (probably *Oreopanax reticulatum*, Fig. 2676, Vol. IV, which is *Meryta Denhamii*). Cuttings of it about the thickness of an ordinary pencil may be secured, and established in small pots, when they may

3113. Terminal leaflet of *Polyscias fruticosa*. Adapted from Blanco, Flora de Filipinas; much reduced.

be cut back to a little above the base, and the cion inserted. Either the cleft or wedge method has been successful. They must be kept in a night temperature of not less than 70°F., and placed in a tight moist case until they unite. Aralias may also be propagated from cuttings, eyes, or pieces of the root. A plant that has become bare of leaves may be cut down near the pot; the stem should be cut in 2-inch lengths, and put in as

eye-cuttings, in a brisk heat in the propagating-bed. The old stool may be put in bottom heat, when many of the varieties will throw several nice cuttings from the base. These should be removed with a heel, when about 6 inches long, and put in as cuttings, in a bottom heat of about 75°, and potted off when rooted. To procure root-cuttings, one of the strongest plants should be turned out of the pot, and the soil washed out of the roots with a hose. Cut the stronger parts of the roots in 2-inch lengths, and place in small pots. The

end nearest the stem should be nearest the surface of the pot. Plunge the pots in a tight case, in 70° to 75° bottom heat, and water carefully until they throw up shoots.—A sandy peat is the best soil in which to grow the finer rooting varieties. The stronger-growing kinds thrive in a richer compost,—say two parts fibrous loam, one part leaf-mold, a little well-rotted manure, charcoal, and sand enough to keep the whole porous. Greenhouse kinds should be in a night temperature of not over 50° when established in their pots. They may be set outdoors in a shady position in summer. The tropical kinds must be kept at not less than 60° night-temperature. Aralias must at all times be shaded from strong sunshine. Watering with soot-water gives a nice gloss to the foliage. *Aralia*, or *Panax*, *Victoria* may be treated the same as the other aralias. Insect pests can be kept in check on aralias by the syringe and by fumigating with hydrocyanic gas, one-half ounce to the thousand cubic feet. The usual precautions of lowering the temperature to 60°, and having the foliage dry when the operation is performed, should be observed. (George F. Stewart.)

paniculata, Baker (*Terminalia elegans*, Hort. *Gilbertia paniculata*, DC.). Erect glabrous shrub: lvs. pinnate, 6–9 in. long, usually with 7 lfts. of which the terminal one is 7–9 in. long, oblong and obtuse, shining, deltoid or somewhat rounded at base: fls. in somewhat spicate (not paniculate) racemes 2–4 in. long, on very short and thick pedicels and not articulated; petals and stamens about 16; fr. hemispherical, with 6 styles and as many grooves. Mauritius.—This is another example of the confusion which arises from the naming of garden plants before their fls. or frs. are known. For several

years this plant was supposed to be a *Terminalia* (cf. G.C. III. 2, p. 366).

pinnata, Forst. (*Aralia latifolia*, Wight & Arn.). Lfts. orbicular to oblong, either nearly entire or with small and remote teeth, the base obtuse or heart-shaped, the apex acuminate: fls. 5–7 in each umbel of the panicle. Malaya.—The *Aralia latifolia* of gardeners may not be the above plant, and it seems to be little cult.

fruticosa, Harms (*Panax fruticosum*, Linn. *Aralia fruticosa*, Hort. *Nothopanax fruticosum*, Miq. *Panax excelsum*, Hort., at least in part). Fig. 3113. Erect shrub, to 6 or 8 ft. high, glabrous, the young branches with prominent lenticels: lvs. more or less irregularly pinnately 3-compound, the petiole and rachis more or less spotted, and the petiole-base expanded and clasping; lfts. stalked, with the segms. also stalked and parted or cut into narrow-ovate or oblong or lanceolate ultimate segms. with scariously spinulose-toothed margins and very acute apices, the whole lf. having a much-divided soft appearance: infl. terminal and in the upper axils, 3–6 in. long and many-fld., the fls. umbellate and short-pedicelled: fr. broad-ovoid, compressed, more than 1 in. long. Polynesia to India, commonly cult. and in many lf.-forms. In some cases the lvs. are much cut and the segms. are reduced to very narrow even to linear or thread-like forms. Var. *plumata*, Bailey (*Panax plumatum*, Hort. *Nothopanax fruticosum* var. *plumatum*, Merr.), has smaller lvs., 8 in. or less long, the ultimate segms. much smaller and finer and mostly lanceolate or linear-lanceolate. See also *Panax Deleuanum*, suppl. list, p. 2748.

Guilfoylei, Bailey (*Aralia Guilfoylei*, Bull. *Nothopanax Guilfoylei*, Merr.). Figs. 3114, 3115. Erect glabrous shrub, to 15 ft. and more, not much branched, with bright green usually white-edged foliage: lvs. large, often 16 in. and more long, regularly pinnate, with more or less spotted or lined petiole which is expanded and clasping at base; lfts. stoutly short-petiole, well separated from each other, ovate to elliptic-ovate to nearly orbicular, tapering or rounded or truncate at base, with distinct and mostly rather remote short teeth which are sharply acuminate-pointed, in the usual cult. forms with white margins or variously white-shaded and blotched; terminal lft. large, often 6 in. long and 5 in. broad. Planted in tropical countries about yards and for screens or hedges, and probably native somewhere in the Pacific Isls.; often called "wild coffee" and "coffee tree," probably from the foliage. It may be seen now and then in greenhouses, although mostly in the smaller and cut-lvd. forms. It appears rarely to produce flowers. Its origin is not traced; by some it is thought to be a modified form of *P. pinnata* or some related recognized species. F.M. 1874:100.—*A. Guilfoylei* appears to have been first described in Bull's Catalogue for 1873 under "new plants announced for the first time," as fol-

3115. *Polyscias Guilfoylei*. ($\times \frac{1}{2}$)

3116. *Polyscias Guilfoylei* var. *laciniata*.

lows: "This fine and distinct ornamental stove plant is a native of the South Sea Islands. It is of shrubby habit, with an erect stem, copiously dotted with lenticular markings, and having pinnate leaves on longish smooth terete petioles, and made up in the case of young plants of from three to seven stalked oblong-elliptic bluntish leaflets which are sometimes obscurely lobed, and irregularly spinose-serrate; these leaflets vary in size from two to three inches long, and are neatly and evenly margined with creamy white, the surface being in addition occasionally splashed with gray."

Var. *laciniata*, Bailey (*Panax laciniatum*, Hort.), Fig. 3116, has the white margins of the lfts. deeply cut into very narrow spreading divergent teeth. Var. *monströsa*, Bailey (*Aràlia monströsa* and *Panax monströsum*, Hort.), has the lfts. irregularly cut and jagged, often very oddly so and of different sizes and shapes, the margins white and deep-toothed: one of the many lf.-forms which are named *laciniata*, *monströsa*, etc. R.H. 1891, p. 225. Gn. 39, p. 565. A form with golden green variegation is *Panax monströsum aureum* of the lists. Var. *Victoriæ*, Bailey (*Panax Victoriz*, Rod. *Aràlia Victoriz*, Hort. *Nothopanax fruticosum* var. *Victoriæ*, Merr.). Fig. 3117. A small close-growing plant (as seen in cult.) with much-divided lvs., the lfts. or segms. small and of different sizes and shapes. A good compact form, frequent in greenhouses, which constantly sends up new stalks and yields recurving tasselled light green white-margined foliage; recommended as a good table plant. G.C. II. 19:405. I.H. 31:521.

Balfouriana, Bailey (*Aràlia Balfouriana*, Sander. *Panax Balfourii*, Sander). Compact and bushy shrub, in cult. well furnished with foliage from base to top: st. bronze-green, speckled with gray: lvs. with long slender petioles (3-5 in. long) which are more or less marked and lined and dilated-clasping at base; lfts. usually 3, long-stalked, orbicular or reniform in outline, cordate at base, very obtuse or broad at apex, coarsely

3117. *Polyscias Guilfoylei* var. *Victoriæ*.

crenate or crenate-dentate, the teeth apiculate and sometimes with minor spinulose serratures, margined or blotched with white. Intro. from New Caledonia.—Thought to be a form of *P. pinnata* by some. *R. Rumphiana*, Harms, is to be studied in this connection.

filicifolia, Bailey (*Aràlia filicifolia*, Moore. *Panax filicifolium*, Hort. *A. spectabilis*, Hort.). Fig. 3118. Strong erect glabrous shrub, with large lenticles and usually with purplish branchlets: lvs. variable, even on the same plant as it attains age (as in Fig. 3118); as commonly seen in cult. young plants, the lfts. are long-lanceolate or narrowly oblong-lanceolate,

narrowed at base, and deeply pinnatifid, the narrow acute segms. being spinulose-serrate; on older shoots or plants, the lfts. may be much larger and broader, still narrow at the base, and merely spinulose-dentate; as the plant matures it produces also very broad-ovate or broad-oblong thick nearly or quite entire lfts., with broad or truncate or even subcordate base, very unlike those already described. Pacific Isls. I. H. 23: 240. J. H. III. 48:337. R. H. 1891, p. 224. Gn. 39, p. 565.—Known in some places in tropics as "angelica."

The above account comprises the cult. aralias that are most likely to be met with and to be referred to this group. Undoubtedly some of the garden names under *Panax* belong in *Polyscias*. The following are names under *Panax* (not under *Polyscias*) which are in doubt or of which combinations appear not to be recognized under *Polyscias*: *Panax cochleatum* DC. (*Nothopanax cochleatum*, Merrill). Erect shrub, to 10 ft.: lvs. simple, 2-5 in. across, nearly orbicular, cordate, somewhat concave

3118. *Polyscias filicifolia*. All leaflets of the same plant. ($\times \frac{1}{2}$)

above, remotely spinulose-dentate. Cult. in Pacific tropics.—*P. crispatum*, Bull. (*Nothopanax crispatum*, Merrill). Shrub, to 6 ft.: lvs. triangular, decompound, the lfts. deeply incised and toothed, oblong-ovate to broad-ovate, green, the lateral ones overlapping. Probably Brazil, but widely disseminated in tropics.—*P. Deleauianum*, Hort., is properly *P. fruticosum* var. *Deleauanum*, N. E. Br. A variation with irregularly pinnate lvs. and digitately cut segms., the ultimate segms. variable, but cuneate at base, toothed and cut and white-toothed. Polynesia. I.H. 30:492. Known also as *Aralia Deleauana*.—*P. diffusum*, Bull. Form of *P. fruticosum*, with bright green, crisped lfts., which are linear-oblong and spiny-toothed. Polynesia.—*P. dissectum*, Bull. Erect, branching, the 2-pinnate lvs. drooping, the lfts. cuneate-obovate and toothed and often 2-lobed.—*P. divaricatum*, Sieb. & Zucc. = *Acanthopanax divaricatus*, p. 193.—*P. dumosum*, Bull. Short-stemmed: lvs. roundish ovate, pinnately divided, the variable ultimate divisions spiny-toothed.—*P. fissum*, Bull. St. marked with pallid spots: lvs. 3-pinnate, the lfts. linear-lanceolate and whitish toothed. Polynesia.—*P. lepidum*, Bull. Compact: lvs. biternately divided, the end division largest; pinnules or ultimate lfts. obliquely obovate, the central one in each case small (sometimes almost rudimentary) and more or less covered by its 2 lateral ones, the margins spiny-toothed and cut. Brazil.—Recent. Scarcely known in cult. in Amer.—*P. Mastersianum*, Sander. Of climbing habit, with long-stalked drooping pinnate lvs. about 3 ft. long, the petiole greenish, tinged with pink and marked with white, the lfts. oblong-lanceolate and toothed. Solomon Isls. G.C. III. 23:242.—*P. multifidum*, Hort., is properly *P. fruticosum* var. *multifidum*, N. E. Br. Compact plant, with 3-pinnatisect lvs. and linear or linear-lanceolate segms. $\frac{1}{2}$ in. or less long, with bristly teeth.—*P. Murrayi*, Muell. (*Aralia splendidiissima*, Hort.). Tree in its native place, with drooping, shining green pinnate lvs. 3-4 ft. long, and many oblong-lanceolate lfts. 3-6 in. long; umbels of brownish fls. in long, terminal panicles. S. Sea Isls. Austral. B.M. 6798. Perhaps true *Aralia*.—*P. nitidum*, Bull. Compact: lvs. roundish obovate, toothed and somewhat spiny, sometimes with deep incisions. Brazil.—*P. ornatum*, Bull. (*Nothopanax ornatum*, Merrill). Slightly branched shrub, to 10 ft.: lvs. long, pinnate, the 11-17 lfts. narrow-lanceolate and deeply blunt-toothed, sometimes pinnately lobed, irregular in shape: fls. greenish white, the panicles terminal or in the upper axils: fr. about $\frac{1}{2}$ in. long, purple. Probably Brazil, but widely cult. in tropics.—*P. sessiliflorum*, Rupr. & Max. = *Acanthopanax sessiliflorum*, p. 192.

L. H. B.

POLYSTACHYA (Greek, referring to the many spikelets). *Orchidaceæ*. Tropical epiphytic orchids, few of which have showy flowers.

Sepals connivent or subpatent, the lateral ones connate with the short foot of the column into a mentum; column short: flowering sts. short, few-lvd., pseudobulbous.—About 80 species. For cult., see *Orchid*.

lutæola, Hook. (*Dendrobium polystachyon*, Swartz). Height 6–12 in.: lvs. oblong-linear or lanceolate-oblong, exceeded by the st.: fls. small, greenish yellow; lip 3-lobed to the middle. S. Fla. and Trop. Amer.

P. appendiculata, Kränzl. Fls. small, yellow; upper sepal with short, subulate, spur-like appendage attached to back a little above base. Trop. Afr.—*P. bicolor*, Rolfe. Plant very small: sts. tufted; lvs. lanceolate-oblong; scapes 3–5 in. long; fls. small; sepals light purple; petals cream-white. Seychelles.—*P. campyloglossa*, Rolfe. Lvs. oblong or linear-oblong, 2–4 in. long; scape 2 in. long; 1- or few-fld.; fls. green, with brown on foot of column and base of lip. Trop. Afr.—*P. coriacea*, Rolfe. Lvs. linear-oblong, 4–6 in. long; racemes densely-fld., sparingly branched at base; fls. minute, deep yellow. Cent. Afr.—*P. dendrobiflora*, Reichb. f. Fls. up to 20 together, in a short corymb, white, suffused with pale rose, resembling in size and shape *Dendrobium*. Fytchianum.—*P. ensifolia*, Lindl. Sts. erect, bearing linear-oblong lvs. 4–6 in. long; fls. numerous, tawny yellow, borne on an erect infl. Trop. Afr.—*P. flexuosa*, Schlecht. Scape slender, about 1 ft. long, terminated by a lax raceme of small white fls. with a purple-spotted lip. E. Trop. Afr. G.C. III. 44:276.—*P. golungensis*, Reichb. f. Plant about 4 in. high; infl. branched, with many small light yellow fls.—*P. Haroldiana*, Hort. Fls. white, sepals tinged with green, borne on a short spike. Trop. Afr.—*P. Laurentii*, Wildem. Plant trailing; lvs. fleshy, green; fls. in panicles, white or cream-white. Congo.—*P. Laurenciana*, Kränzl. St. pubescent; raceme 4–8-fld.; fls. yellowish green, the lip rose-pink; sepals spreading, puberulous, the dorsal ovate, acute, about $\frac{1}{2}$ in. long; petals incurved, oblong-oblancoate, subobtusate, about as long as sepals; lip 3-lobed, about $\frac{1}{2}$ in. long, the front lobe fleshy, nearly orbicular. Trop. Afr. B.M. 8211.—*P. mystacidioides*, Wildem. Sts. branched, over 3 ft. long; lvs. lanceolate, dull green, covered with tiny dots; fls. lurid purple and flesh-colored, $\frac{1}{2}$ in. long, solitary. Congo.—*P. paniculata*, Rolfe. Pseudobulbs flattened, the young shoots blotched with purple; racemes paniced; fls. from coppery yellow to reddish orange. Trop. Afr. G.C. III. 48:462; 58:85. B.M. 8618.—*P. repens*, Rolfe. Small, creeping; fls. about $\frac{1}{4}$ in. long; sepals and petals buff-yellow striped with brown; lip deep red-brown. Uganda.—*P. stricta*, Rolfe. Panicle erect, 9 in. long; fls. $\frac{1}{2}$ in. long, light greenish yellow, with faint purple streaks. Trop. Afr.

GEORGE V. NASH.†

POLYSTICHUM (Greek, *many rows*; referring to the sori). *Polypodiaceæ*. A group of ferns mostly of temperate regions, some species of which do well in living-rooms.

Veins free and the roundish sori covered by indusia that are peltate and attached to the leaf by a short central stalk. They are mostly easily grown and thrive best in shade. One species is very commonly grown for fern-dishes. All the species have also been described by some authors under the genus *Aspidium*. For culture see *Ferns*.

INDEX.

acrostichoides, 2.	capense, 12.	Richardii, 10.
aculeatum, 6.	coriaceum, 12.	tensemense, 7.
amabile, 11.	lepidocaulon, 4.	Tsus-sinense, 7.
angulare, 8.	Lonchitis, 1.	varium, 14.
aristatum, 13.	munitum, 3.	viviparum, 5.
Braunii, 9.	proliferum, 6.	

A. Lvs. simply pinnate throughout.

B. Lower pinnæ gradually reduced to mere lobes.

1. **Lonchitis**, Roth (*Aspidium Lonchitis*, Swartz). HOLLY FERN. Lvs. 9–20 in. long, rigid, the pinnæ broadly lanceolate-falcate, the lowest triangular. N. Eu. and Amer., mostly in high latitudes.

BB. Lower pinnæ scarcely if any smaller than those above.

2. **acrostichoides**, Schott (*Aspidium acrostichoides*, Swartz). CHRISTMAS FERN. DAGGER FERN. Figs. 3119, 3120. Lvs. growing in dense crowns, with stalks 6–8 in. high, the pinnæ linear-lanceolate, somewhat falcate, and serrulate with appressed teeth; spore-bearing pinnæ contracted, with confluent sori. E. U. S.—One of our commonest species. The common name is due to the evergreen character of the lvs. which are picked by the thousand and sold in bales to florists.

3. **munitum**, Kaulf. (*Aspidium munitum*, Kaulf.). Stalks 4–12 in. long, chaffy at base or throughout; pinnæ long, linear-acuminate, serrate or doubly ser-

rate; sori in a single row midway from midrib to margin. Utah northward and westward.

4. **lepidocaulon**, Hook. Stipes densely clothed with large, heart-shaped scales: lf.-blades short, with 12–15 pairs of pinnæ, unequal-sided, scarcely toothed; sori usually in two rows. Japan.

3119. Christmas fern.—*Polystichum acrostichoides*.

AA. Lvs. with auricles of pinnæ forming distinct lfts.

5. **viviparum**, Fée. Lf.-blades 12–18 in. long, 4–6 in. wide, with numerous lanceolate pinnæ; lower basal margin obliquely truncate; sori in 2 or 4 rows. W. Indies.

AAA. Lvs. bipinnate in the lower two-thirds.

B. Pinnules auricled.

6. **aculeatum**, Roth (*Aspidium aculeatum*, Swartz). Lf.-blades 2 ft. or more long, 6–8 in. wide; pinnules twice as long as wide, with very conspicuous basal auricles. Eu. and Calif. Hardy.—*P. proliferum*, Hort., is an Australian form producing buds on the lvs. A large number of varieties are grown and offered for sale by English florists, but they are not of a sort to be of value in American trade.

7. **Tsus-sinense**, J. Smith (the name is often incorrectly spelled *tensemense* in the trade). Fig. 3121. Lvs. commonly 6 in. long, 2–3 in. wide, the petioles slender, dark, the lvs. dark green.—Somewhat like *P. aculeatum* but well distinguished both in size and general appearance. This is one of the ferns commonly used for fern-dishes.

8. **angulare**, Willd. Lf.-blades 1–2 ft. long, rather narrowly lanceolate; pinnules nearly triangular, two-thirds as broad as long, more or less incised. Eu.—Another favorite with English growers who offer many varieties. Hardy. See *P. aculeatum* above.

9. **Braunii**, Lawson. Lf.-blades 18–24 in. long, narrowly elliptic-lanceolate; pinnules 7–10 pairs to each pinna, broad, the upper basal edge parallel with the rachis. Europe and mountain regions of eastern America.—Sometimes considered a variety of *P. aculeatum*.

3120. Details of tip of fertile leaf of *Polystichum acrostichoides*. a, sori; b, indusium.

BB. *Pinnules scarcely auricled.*

10. *Richárdii*, Hook. Lf.-blades 9-18 in. long, ovate-deltoid, with 12-15 pairs of pinnæ; pinnules deeply toothed, texture coriaceous. New Zeal.

11. *amabile*, Blume. Lf.-blades 1 ft. or more long, 6-9 in. wide, with a lanceolate terminal pinna and 3-6 pairs of lateral ones; pinnules sub-rhomboidal, the upper and outer portions sharply spinulose serrate. India, Japan, and E. Indies.

AAAA. *Lvs. more than twice pinnate in the lower pinnae.*

12. *capense*, J. Smith (*P. coriæceum*, Swartz). Stalks scattered, 1-2 ft. long; lf.-blades 1-3 ft. long, leathery, sub-deltoid, the segms. lanceolate and bluntly lobed, the teeth not mucronate. S. Afr., S. Amer., and New-Zeal.

3121. *Polystichum Tsus-sinense*. (Small plant.)

13. *aristatum*, Swartz. Stalks scattered, 12-18 in. long, scaly below; lf.-blades 1-2 ft. long, 9-12 in. wide, 3-4-pinnatifid, the lower pinnae largest; texture firm, glossy; sori in 2 rows near the midrib. Japan to Ceylon and Austral.

14. *vàrium*, Presl. St. partly creeping; lvs. $1\frac{1}{2}$ -2 ft. long, 9-12 in. wide, narrowly triangular, 3-pinnate in lowest pinnae, somewhat leathery. Japan, China.—Similar to *P. capense*.

L. M. UNDERWOOD.
R. C. BENEDICT.†

POMADÉRRIS (Greek, *lid* and *skin*, said to allude to the membranous covering of the capsule). *Rhamnaceæ*. Shrubs, more or less covered with hoary or ferruginous stellate tomentum. The Victorian hazel, *P. apetalà*, is included here.

Leaves alternate; fls. numerous, in small cymes usually forming terminal or axillary corymbs or panicles; calyx-tube adnate to the ovary, limb 5-parted, deciduous or reflexed; petals 5 or wanting; stamens 5, the filaments elongated and often suddenly attenuate and inflexed at the top; ovary more or less inferior: caps. small, the upper portion protruding above the calyx-tube, 3-valved.—About 22 species confined to Austral., New Caledonia and New Zeal. Several species have been cult. in England at different times but *P. apetalà* seems to be the one most commonly cult. Prop. by cuttings of half-ripened shoots.

apétala, Labill. Shrub or small tree, 6-15 ft. high, rarely more; lvs. 2-4 in. long, oblong-ovate, obtuse or

subacute, irregularly crenulate: panicles 3-7 in. long, terminal and axillary; calyx-tube short, stellate-tomentose; petals wanting: caps. obtuse, sparsely stellate-tomentose. Austral. and New Zeal.—Cult. in Calif. for ornament. Von Mueller in his "Select Extra-Tropical Plants," says it is "a tree attaining a height occasionally of 60 ft., but mostly smaller. The foliage is devoured with avidity by pasture animals, often in preference to ordinary good feed."

P. vacciniifolia, Reiss, an Australian species with ovate or nearly orbicular lvs., cream-colored fls. in ovoid terminal panicles and with broad petals, has been cult. in England. G.C. III. 35:339.

F. TRACY HUBBARD.

POMEGRANATE is the vernacular of *Punica Granatum*, a small tree of southern Asia, grown both for ornament and for its edible fruit (Fig. 3122). See *Punica*. It is somewhat grown in the open in the southern states, and also as a pot- or tub-plant in greenhouses in the North.

The natural habit of the pomegranate is of rather bushy growth, but by careful training a tree 15 to 20 feet may be produced. This, however, seems possible only in the southern sections of the United States. A great many shoots spring from the base of the plant; these should be cut out, as it is contended that they withdraw the nutriment which should go to the fruit-bearing stems. The branches are slender, twiggy, nearly cylindrical, somewhat thorny. The leaves are lanceolate, long, narrow, glossy green and with red veins. The flowers have a red thick fleshy calyx, crowned with bright scarlet crumpled petals and numerous stamens. The fruit is globular, topped with a crown-like calyx, and the interior consists of numerous seeds enveloped in a bright crimson or pink-colored pulp, seeds being arranged in segments, separated by a thin skin, and very acid in the typical variety. A cooling acescent drink, known as granadine, is made from the pulpy seeds, with the addition of water and sugar. This is much used in the South, and in certain parts of Europe, and is especially grateful in fevers. This plant will succeed as far as the 35th degree of latitude north, but during extreme cold periods, the plants are sometimes injured by cold in that latitude. For higher latitudes it should be cultivated in tubs, and given a conservatory during winter. For some sections of the South it is used for hedges. The fruit begins to ripen about September and can be kept for several weeks.

The pomegranate is multiplied by hardwood cuttings planted in open ground during February, or by layers and also by softwood cuttings during summer. As the plant forms many shoots, these are often used, as they usually are provided with rootlets. In Florida, Georgia, Alabama, Louisiana, and some of the other southern states, pomegranates are grown commercially and are shipped to the northern and eastern markets. There is a growing demand for the fruit of the pomegranate.

The pomegranate is supposed to have been introduced into southern Europe by the Carthaginians, whose Latin name of "Punicus" was thus given and derived. A reference is also found in the sacred scriptures. Theophrastus described it 300 years before the Christian era, and Pliny considered it one of the most valuable fruits, both as to its beauty and medicinal properties. The bark of the

3122. Pomegranate, in lengthwise section. ($\times \frac{1}{4}$)

root is a well-known astringent employed in therapeutics, in dysentery and diarrhea; the rind of the fruit, when boiled, has for many generations past been the remedy for tenia, and a jet-black smooth writing ink is also made of it.

The pomegranate is a native of some parts of Asia, and by some botanical authors is said to be found also in northern Africa and China. Although of such ancient origin and cultivation, there are but few varieties of the fruit-bearing section disseminated in this country and Europe, but, according to Firminger, several fine varieties have been grown in Bengal from seed brought from Cabul, one being seedless, another growing to the size of "an ordinary human head" and still another as large as a small shaddock.

Varieties grown for fruit.

Acid, or Wild.—With a sharp acid pulp: fruit often very large, from 3 to 4 inches diameter and with a bright-colored rind.

Dwarf.—A form of the Acid variety, of very low and bushy growth: flowers single; fruit from 1½–2 inches diameter; pulp very acid. This can be grown in a pot, as it fruits very abundantly.

Paper Shell.—Very large, juicy, very sweet, and of excellent quality; skin thin, pale yellow with crimson cheek; sides crimson: fine grower: good bearer and ships well.

Rhoda.—Fruit crimson, of large size; skin thin but tough; crisp, sweet, and of exquisite flavor.

Spanish Ruby, or Purple-seeded.—As cultivated in Louisiana, seems to be only a form of the Subacid. Fruit large and bright-colored with deep crimson pulp. It is considered the best of its class.

Subacid.—Differs only from the Sweet in the more acidulated pulp.

Sweet.—Fruit usually somewhat smaller than the Acid and with a darker-colored rind; pulp sweet.

Wonderful.—This is said to be the largest of all pomegranates: fruit sometimes 5 inches diameter, bright crimson; pulp highly colored; very juicy; fine flavor: ripens early: good shipper.

All these varieties are very ornamental from their abundant yield of bright scarlet flowers, which are produced upon the extremities of the young branches of the same year's growth. When the plant is grown in a tree form, the branches should be annually cut back after the leaves drop.

Varieties grown for ornament (non-fruited).

Double Dwarf, or Punica nana racemosa.—Of dwarf growth, with bright scarlet double flowers, which are borne in clusters. This is especially desirable for growing in pots, as its flowers are abundant and lasting.

Double Red.—With a very large calyx, from which protrude numerous large bright scarlet petals, larger than those of the common single type. These are produced in abundance during summer and fall and resemble a bright scarlet pompon.

Double Variegated, or Legrellei.—A very handsome variety with very large flowers, the petals being striped and mottled with yellow and scarlet. Double red blooms will frequently be found on the same stem with variegated blooms. As this is a sport of the Double Red it frequently reverts.

Double Yellow.—Similar to the above in shape of flower, but latter are of a pale yellow color.

Double White.—Form of flower is similar to Double Red, but color is pure white. L. A. BERCKMANS.†

POMELO (contraction of *pomplemoose*?). A name sometimes used in the East Indies for pummelo and in the United States for the grapefruit. Inasmuch as there are very many different varieties of *Citrus grandis*, it seems best to retain pummelo in its common East Indian sense as a generic term for all of them and to

apply to the special form grown in the West Indies and the United States its old name grapefruit. The use of pomelo (a mere variant of pummelo) for the grapefruit is likely to lead to confusion, especially as growers, shippers, dealers, and consumers all continue to use the name grapefruit. See *Pummelo*.

WALTER T. SWINGLE.

POMOLOGY: *Fruit-growing*, page 1290.

POMPLEMOOSE (Dutch, *pomplemoes*, perhaps from Dutch *pompoen*, pumpkin, and old Javanese, *limoes*, a citrous fruit). A name sometimes used in East India instead of the more common pummelo for forms of *Citrus grandis*.

PONCIRUS (French, *poncire*, a kind of citron). *Rutaceæ*, tribe *Citrææ*. Small spiny deciduous tree native to North China, extensively used as a stock for oranges, also grown for hedges and often for ornament in regions too cold to permit of the culture of citrous fruits.

This plant has been usually referred to Citrus, although DeCandolle, Rafinesque, Miquel, Penzig, Hance, Makino, and other botanists referred it to other genera. It differs from Citrus in having deciduous trifoliolate lvs.: fl.-buds formed in early summer and passing the winter protected by bud-scales: fls. borne on old wood in early spring and nearly sessile, with petals opening flat and narrowed to a claw-like base;

3123. *Poncirus trifoliata*. (X ½)

stamens entirely free; ovary 6–8- (usually 7-) celled: fr. densely and finely pubescent, the pulp vesicles containing oily matter in drops and having hair-like appendages which secrete a viscous fluid, the ovary wall showing orange-colored cellular eruptions between the bases of the pulp vesicles; pith with transverse plates of thick-walled cells; stomata of the green twigs situated at the bottom of deep narrow pits; and seedlings with spirally arranged cataphylls, the lowest bract-like, the uppermost gradually merging into foliage-lvs. In view of these numerous differences, all of them of taxonomic importance, there can be no doubt of the validity of the genus Poncirus.

trifoliata, Raf. (*Citrus trifoliata*, Linn. *Citrus fuscata*, Lour. *Pseudægle sepiaria*, Miq. *Pseudægle trifoliata*,

Makino. *Egle? sepiaria*, DC. *Limonia? trichocarpa*, Hance. *Citrus triptera*, Carr.): TRIFOLIATE ORANGE. Figs. 3123-3125. A small tree, spines long and stout: lvs. deciduous, trifoliate, often borne in tufts on old wood (see Fig. 3123); terminal lfts. $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long, lateral ones 1-2 in. long, sessile, petiole slightly winged: fls. $1\frac{1}{2}$ -2 in. across, white, the corolla opening nearly

3124. Flowers of *Poncirus trifoliata*. ($\times \frac{1}{2}$)

flat, and the petals narrowed to a claw at base (Fig. 3124), stamens free, ovary 6-8 (generally 7-) celled: fr. very fragrant, dull lemon-colored, like a small orange in shape, but only $1\frac{1}{2}$ -2 in. diam., and covered with fine downy hairs, oil-glands of peel abundant, filled with a very disagreeably flavored oil, pulp scanty, very aromatic, seeds ovoid, plump, very numerous, leaving little space for pulp. Illus. Kaempf. Amoen. 801. B.M. 6513. G.C. III. 27:269. Penzig, Studi sugli Agrumi, Atlas, pls. 13, 14. U. S. Dept. Agric. Yearbook 1904, pl. X. U. S. Dept. Agric. B.P.I. Circ. No. 46, figs. 1-6, pl. 1. Comptes rendus 4 me Confer. Internat. Génét., p. 386.—The trifoliate orange has been known in N. China since ancient times, being repeatedly referred to in early works, and it was described and figured in the Chêng lei pen ts'ao, printed in 1108 A.D. It was early intro. into Japan and definitely referred to in the *Mannyô shû*, a Japanese MSS. work dating from the 8th century. Var. *monstrôsa*, Swingle (*Citrus trifoliata* var. *monstrôsa*, T. Ito in Encyclopedia Japonica, 2:1056). HIRYÔ, or FLYING DRAGON. This is a curious, very dwarf variety with tortuous branches and curved spines. The lvs. are very small and inconspicuous as the lfts. are often reduced to mere filaments on which the oil-glands appear as node-like thickenings. This variety is esteemed in Japan for cult. as a dwarfed pot-plant. The writer introduced it from Japan into this country in 1915.

The hybrids between *Poncirus trifoliata* and the common orange are called citranges. A number of varieties, Rusk, Colman, Morton, and so on, are grown for home use in the cotton-belt, north of the limit of successful orange-culture. See *Citrang*. Promising hardy hybrids have been made at the Department of Agriculture under the writer's direction between *P. trifoliata* and a number of other species of citrus fruits, such as the sour orange, mandarin, grapefruit, lemon, lime, calamondin, kumquat (*Fortunella* sp.), and others. These are being tested in the field.

The principal use of the trifoliate orange is for stock upon which to graft the commonly cultivated citrus fruits. It is especially well adapted to rather rich somewhat moist, sandy loam soils, preferably with a clay subsoil, such as are common around the Gulf Coast. It is not at all adapted to light sandy soils, nor to strongly calcareous soils. Almost all kinds of citrus

fruits grow readily on trifoliate stock but are dwarfed somewhat and usually forced into early bearing. The Satsuma orange as grown commercially in this country is practically limited to this stock as it does not grow at all on sour orange stock and succeeds only very imperfectly on sweet orange stock. Trifoliate stock is also very widely used in Japan. In the states south of the Potomac and Ohio rivers the trifoliate orange is sometimes used for hedges, for which purpose it is well adapted because of its dwarfed habit, strong thorns, handsome flowers, foliage, and fruits. Even in winter after the leaves have fallen its twigs remain green. It is very widely used for hedges in Japan. *P. trifoliata* is also of value as an ornamental tree for lawn planting, for which purpose care should be taken to secure large-flowered forms. It can be grown for this purpose as far north as Philadelphia. The trifoliate orange shows surprisingly little variation. Millions of seedlings are grown every year in the larger citrus nurseries of this country but it is rare to see any perceptible variation in the character of the leaves and twigs. The flowers, however, do show variation, often having a partial staminody of the petals (rarely complete) which makes them smaller and less handsome than the normal large flowers. The fruits are usually nearly spherical but rarely are somewhat elongate and papillate, much like a very small lemon.

WALTER T. SWINGLE.

POND-APPLE: *Annona glabra*. P. Lily: *Nuphar*. P.-weed: *Potamogeton*.

PONGAMIA (a native Malayan name): *Leguminosæ*. A single arborescent or shrubby species of tropical Asia and Australia, little known in this country.

Leaves odd-pinnate; lfts. opposite: fls. racemed; calyx campanulate, nearly truncate; corolla much exerted; standard broad; keel obtuse, the petals cohering at the tip; stamens monadelphous, the upper filament free low down; anthers oblong, versatile; ovary subsessile, 2-ovuled; style incurved, glabrous; stigma capitate: pod flattened, oblong, indehiscent, not at all winged or thickened at the sutures. It is related

3125. *Poncirus trifoliata*.

to *Piscidia* but differs from it by having the pods short, compressed, smooth, and 1-seeded instead of elongated, winged, and several-seeded.

pinnata, W. F. Wight (*Cytisus pinnata*, Linn. *P. glabra*, Vent. *Pongam pinnata*, Wight. *Galedipa indica*, Lam.). A tall erect tree or climber, with glabrous branches and lvs.: lfts. 5-7, opposite, subcoriaceous, oblong or ovate, pointed, stalked, 2-4 in. long; fls. in a simple peduncled axillary raceme, nearly as long as the lvs.; pedicels 2-4 joined together, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, with a pair of minute bractlets in the middle; corolla $\frac{1}{2}$ in. long, standard silky on the back; pod woody, glabrous, $\frac{1}{8}$ - $\frac{1}{4}$ in. thick, $1\frac{1}{2}$ in. long, with a short decurved point. Intro. into U. S. in 1910.—Suitable as an ornamental in the southern states. The ash of the wood is used for dyeing. The seed yields a thick reddish-brown oil used for illuminating and medicinal purposes. The foliage is bright and very handsome. The tree sometimes reaches a height of 40 ft. Grown in S. Calif.

P. L. RICKER.

PONTERDÈRIA (G. Pontederia was an Italian botanist, 1688-1757). *Pontederiaceae*. Perennial herbs of bogs and ponds with strong horizontal rootstocks, frequently used in water-gardens, and for naturalizing in wet places.

Leaves long-petioled, root-lvs. with a sheathing stipule within the petiole; infl. a 1-lvd. st. bearing a spike of violet-blue ephemeral fls.; perianth funnel-form, 2-lipped, the 3 upper segms. united to form the 3-lobed upper lip, the 3 lower spreading and clawed; stamens 6; ovary 3-celled, 2 of the cells empty.—Two or 3 species from N. and S. Amer.

Pontederias are well worth cultivation in bog-gardens and shallow ponds, and *P. cordata* is offered by dealers in native plants. It thrives best in water 10 to 12 inches deep. It transplants with ease. Propagated mostly by division. It grows as far north as Nova Scotia and Minnesota, and therefore is perfectly hardy in all parts of the country.

cordata, Linn. PICKEREL-WEED. Growing in clumps: lvs. heart-shaped, blunt, from a spathe-like bract; upper lobe of perianth marked with a pair of yellow spots (rarely all white); calyx-tube in fr. crested with 6-toothed ridges. Nova Scotia to Ont., Minn., and Texas. B.M. 1156. Mn. 7:1. V. 2:196; 3:336. G.C. III. 52:466. Var. *lanceifolia*, Morong (*P. lanceifolia*, Muhl. *P. lanceolata*, Nutt.), differs from the type in having lanceolate lvs. N. Amer. B.M. 8108.

For *P. crassipes*, Mart., see *Eichhornia crassipes*, Vol. II, p. 1105.—*P. montevidensis*, Hort., has appeared in the foreign journals but its botanical characters are unknown. G.W. 3, p. 619.

F. TRACY HUBBARD.

PONTHIÈVA (named in honor of M. de Ponthieu). *Orchidaceae*. Terrestrial, glabrous or pilose herbs which are not in common cultivation, though sometimes grown in gardens.

Roots fascicled in a short rhizome: lvs. subradical, ovate or lanceolate, membranaceous, more or less petioled; infl. a lax raceme borne on a simple elongated scape; the pedicels often glandular-pubescent; fls. medium-sized; sepals free, spreading; petals adnate to the column, narrower than the sepals; labellum adnate to the base of the column by a claw, ascending, with the lateral lobes winged; column short or rather long, terete, apex broadened; caps. oblong, erect, beakless.—About 30 species, Trop. and Subtrop. Amer.

glandulosa, R. Br. Plants 1-1½ ft. high, with lanceolate-elliptical, pointed and short-petioled lvs. which are 3-5 in. long; raceme 3-6 in. long; fls. green or greenish brown; outer sepal ovate-oblong, lateral ones flat; petals half-cordate-deltoid; labellum abruptly dilated above the claw, roundish with a terminal, linear appendage. W. Indies and S. Amer. B.M. 842 (as *Neottia glandulosa*).—Formerly offered by a dealer in native plants. Probably not hardy N. F. TRACY HUBBARD.

POPCORN: Corn.

POPLAR: *Populus*. P., Yellow: *Liriodendron*.

POPPY: *Papaver*. California P.: *Eschscholtzia*. Celandine P.: *Stylophorum*. Corn P.: *Papaver Rhæas*. Horned P.: *Glaucium*, *Opium* P.: *Papaver somniferum*. Prickly P.: *Argemone*. Shirley P.: an improved strain of *Papaver Rhæas*. Tulip P.: *Hunnemannia*, Welsh P.: *Meconopsis cambrica*.

PÓPULUS (ancient Latin name, of disputed origin). *Salicaceae*. **POPLAR**. **ASPEN**. **COTTONWOOD**. Soft-wooded trees of rapid growth, some kinds of which are much planted on roadsides and in grounds, particularly when quick results are desired.

The poplars are dioecious, with both staminate and pistillate flowers naked but from a cup-shaped disk, and in slender mostly drooping precocious catkins in which the subtending scales are toothed, cut or cleft at the apex: stamens few or many, usually numerous, on distinct filaments: pistillate fls. with mostly a single 1-loculed mostly sessile ovary with short style and 2-4 often lobed long stigmas: fr. a small 2-4-valved caps., containing cottony seeds, the mature catkin sometimes with a necklace-like or moniliform character: lvs. alternate, stalked, mostly broad: buds scaly, often resinous.—Species probably about 35-40, in the northern hemisphere, mostly extra-tropical, although very many more than this have been described, some of them being hybrids. The poplar of lumbermen is the tulip tree. (See *Liriodendron*.)

Botanically the poplars comprise a most bewildering group, and there is wide divergence of opinion and practice as to the limits and names of species. Many of the cultivated forms are assumed to be hybrids, but the origin of most of them, so far as parentage is concerned, can be little more than conjectured. It is likely that seedlings of some of these hybrids break up into forms much resembling the parents, and thereby still further contribute to the bewilderment. The trees being dioecious, the herbarium specimens may not represent both sexes; as the catkins appear in advance of the foliage, the specimens may not represent the same plant or type; the foliage is very various, sometimes even on the same tree, and specimens are likely to be taken from the lower part of large trees where the leaves are small or from the terminal shoots of young trees on which the leaves are large and have a different character. Of some kinds only one sex is known. The habit of growth is also very characteristic even in species or forms on which the foliage is very similar, but this character is of course not represented in botanical specimens. It will be seen, therefore, that the usual herbarium collection may not have full value in the determination of species. There is naturally a tendency to place great stress on leaf-forms in the description of species, even though in some groups practically the whole range of forms may be found on single trees. These difficulties are particularly marked in this country in the *P. deltoides-angulata* group.

With regard to the variability of the leaves of *Populus*, Schneider writes in "Plantæ Wilsonianæ," "it is helpful to keep the following in mind. L. A. Dode was the first who clearly described the variation of the leaves according to the age of the plants, the position of the branches, and the climatic and other conditions under which they were produced. . . . I think it sufficient if we distinguish three different kinds of leaves: (1) the leaves of the offshoots or suckers (*folia turionum radicalium*); (2) the leaves of the normal but not the vigorous shoots of the young plants (*folia ramorum* [*sed non turionum*] *plantæ juvenilis*); and (3) the leaves of the old trees (*folia arboris adultæ fructiferæ*). The leaves of the third kind we usually find at the ends of vigorous branches of young plants when they are growing well and becoming mature. If we compare leaves of different species it is necessary to be very careful only to compare the same kinds of leaves."

What has been said about the dependence on leaf-characters in descriptions applies also to the horticultural description; it is much needed that the cultivated poplars shall be studied with the purpose to correlate the characters of habit, leaves, buds, twigs, bark, flowers, and fruit.

Probably some of the difficulty in distinguishing native species of *Populus* is due to the fact that we have not recognized the presence of European or other hybrids in this country. It is not unlikely that some of these forms appear even in places remote from habitations, as do the introduced tree willows, and that they have been confused with the native kinds.

There appear to be few important growing collections of poplars in this country, nor have the important cultivated examples in different parts been looked up and studied. Many of the European nursery forms have been introduced here and there; but for ornamental planting practically only two kinds are much called for, the Lombardy and the so-called Carolina, with "Russian poplars" and "Norway poplars" in the prairie and plains country. This is a pity, seeing that some of the forms are most interesting in habit and foliage, and in the red coloring of petioles and midribs, combined with other good features. The hybrid poplars have not been given sufficient attention in North America. Some of the first-generation hybrids are remarkably vigorous. The Russian poplars are undoubtedly of several kinds, mostly, apparently, forms or hybrids of *P. balsamifera* allies. A very large collection of Asiatic poplars was made at the botanic gardens at St. Petersburg and also at the agricultural college at Moscow. The late J. L. Budd introduced many of these forms and they have become widely distributed in the prairie regions. It would not be strange if substitutions had been made in the course of time.

The Norway poplar of the interior region is very like *P. Sargentii* in foliage, but it holds its leaves three weeks later in autumn than the native cottonwood and the central trunk does not break up so quickly, thereby making a better timber tree; it is a very rapid grower. It has proved to be a very valuable tree for Minnesota and the Dakotas and other parts, and is hardy in Manitoba. On account of its very rapid growth and the straight strong trunk, it has been called the "Sudden Sawlog poplar." It appears to have been introduced into North America from Russia by Budd, and is said to have been discovered on the eastern slope of the Altai Mountains. It was disseminated in part in this country by Norwegian settlers and thereby got the name of Norway poplar. Its botanical position or name is undetermined.

Poplars of various kinds are considerably planted on the prairies and plains and form characteristic features on the landscape. Many of them withstand the trying climatic conditions and also grow very rapidly. The many kinds of cultivated poplars, which have been

largely introduced or tried in these regions, stretching into Canada, need careful study by the systematist. They are particularly numerous in the tacamahac or balsam-poplar group and are not well understood. In the irrigated regions of the Rocky Mountain country, the Lombardy poplar has long been a familiar object along ditches and thoroughfares.

The poplars are amongst the easiest of all trees to propagate and to grow. They come readily from hardwood cuttings, as do willows and currants. The weeping varieties are grafted head-high on erect kinds, *P. grandidentata* or its derivatives apparently being used as a stock. Poplars thrive in almost any soil, although the cottonwood is most at home in lowlands and along streams, at least in the East. For shelter-belts they are very useful because of rapid growth and great hardiness. In Europe, where fagots and other similar materials are desired, poplars are often headed-back severely or pollarded, but this practice is very little known in North America. The poplars are also useful for temporary shelter for other trees and bushes. In this respect the common aspen (*P. tremuloides*) is a valuable tree in the reforestation of American lands. It springs up quickly in clearings, and during its comparatively short life holds the soil and protects other vegetation and finally contributes its own substance to the maintenance of the stronger forests. In this way it probably has exerted an effect upon the configuration of our forest areas and upon the fertility of the land from remote time. The same qualities make it valuable, in many cases, in extensive ornamental plantings.

The fault in the planting of poplars is the tendency to plant too many and to allow them to give character to the place. About summer resorts, for example, poplars and willows are used much too freely. They give the place a look of cheapness and temporariness.

They are planted in such places because they grow rapidly and thrive in unfavorable conditions; but it is better to use them for temporary effects, allowing better trees, that are planted with them, gradually to take their places. The legitimate common use of poplars in ornamental grounds is the production of minor or secondary effects. As a rule, they are less adapted to isolated planting as specimen trees than to use in composition,—as parts of general groups of trees,—where their characters will serve to break the monotony of heavier foliage. The poplars are "gay" trees, as a rule, especially those, like the aspens, that have a trembling foliage. Their leaves are bright and the tops thin. A few of them in judicious positions give a place a sprightly air. This is particu-

larly true of the common aspen, *P. tremuloides*, of the woods. Its light twinkling foliage and silver-gray limbs are always cheering and its autumn color is one of the purest golden yellows of our landscapes. It is well to have a tree of it standing in front of a group of maples or evergreens. Its whole expression is then one of familiarity.

On the other hand, the poplars have their interest as specimen trees as distinctly as do other kinds of trees, but one seldom sees well-grown mature examples. The age characters of some kinds of poplars, both in structure and in bark, are as interesting as are those of maples and oaks or other trees. Of many of the planted poplars, old specimens are practically unknown to the public.

The cottonwood (*P. deltoides*) is one of the best poplars for permanent planting. It makes a noble tree, of durable and substantial appearance. But like the aspen, it is cheerful and restive. One is not moved to lie under it, as one is under a maple or an oak. Its leaves

3126. *Populus canescens* above, and *P. alba* var. *pyramidalis* (*P. Bolleana*). ($\times \frac{1}{2}$)

rustle with the lightest movement of air. The ripple of its foliage recalls the play of wavelets on a pebbly shore. The day is never so dark but the cottonwood reflects a flood of light. One should take care, however, to plant only the staminate tree, for the "cotton" of the seeds is very disagreeable on lawns and about dwellings when carried by the wind. In the plains and mountain states, the western cottonwood (*P. Sargentii*) is a characteristic tree.

Some of the forms of the black poplar of Europe are especially satisfactory for the production of lively effects in planting. Of these, one of the most distinct is the form known to nurserymen as *Populus elegans*. It has a most pleasing light and tremulous foliage, the effect of which is heightened by a twiggy character of growth and a reddish cast to the leaf-stalks and young shoots. It is an elegant tree, and well adapted to planting in front of heavier foliage in the most conspicuous part of the grounds.

Some of the silver- or white-leaved poplars produce the most striking contrasts of foliage, especially if set near darker trees. Bolles' poplar (*Populus Bolleana* of the nurseries) is one of the best of these trees. Its habit is something like that of the Lombardy. The upper surface of the deeply lobed leaves is dark dull green, while the under surface is almost snowy white. Such emphatic trees as this should usually be partially obscured by planting them amongst other trees so that they appear to mix with the other foliage, or else they should be seen at some distance. Other varieties

3127. *Populus tremula*. (× $\frac{1}{3}$)

of the common white poplar or abele are frequently useful, although most of them sprout badly and may become a nuisance. The Lombardy poplar (*P. nigra* var. *italica*) is probably the most striking and distinct tree that is suited to planting in the North. As single specimens scattered here and there in mixed plantings, or when seen over or behind buildings, it may be most picturesque and satisfactory; but the tendency is to plant it too freely. The very fact that it is emphatic is the reason why it should be planted sparingly when artistic effects are desired.

The catkins of poplars, particularly the staminate ones, are usually attractive, as they appear in early spring; but they are of short duration. Fig. 3130.

The following sketch includes all the poplars known to be offered by American nurserymen or to be subjects of rather general planting, together with exotic forms that are likely to appear in this country. For literature, see Wesmael, DC. Prodr. 16, pt. 2, pp. 323-31; Sargent, Silva of North America, vol. 9 (quoted below as S.S.). A very recent careful treatment of the poplars appears in Volume VII of Elwes & Henry, "Trees of Great Britain and Ireland;" from this work some of the following characterization is drawn. Subsequently, the black poplars (*P. nigra-deltoides* group) have been worked over by Henry in Transactions of the Royal Scottish Arboricultural Society, 30, pt. 1:

Discussions of the genus of recent date will be found in C. K. Schneider, "Handbuch der Laubholzkunde" (1906) and Dode in Mémoires Société d'Histoire Naturelle d'Autun (1905). For an account of the new and old Chinese species, see Schneider in "Plantæ Wilsonianæ," Vol. III.

For the purposes of this popular treatment, the species of *Populus* may be thrown into six groups:

- I. The white poplars; Nos. 1-3.
- II. The aspens; Nos. 4-7.
- III. The black poplars and cottonwoods; Nos. 8-14.
- IV. The large-leaved poplars and cottonwoods; Nos. 15, 16.
- V. The balsam poplars and tacamahacs; Nos. 17-28.
- VI. The variable-leaved poplars; No. 29.

I. WHITE POPLARS. *Lvs.* mostly strongly angled or lobed and broader than ovate in shape, the mature *lvs.* on the long or verdurous shoots usually white-tomentose or gray-canescens beneath (at least in the cult. forms), *lvs.* on the short or small shoots often becoming glabrous or nearly so and often of different shape from those on the strong-growing shoots; petiole usually cylindrical: terminal buds relatively small and not glutinous.

1. *alba*, Linn. (*P. triloba* and *P. Morisetiana*, Dode). WHITE POPLAR. ABELE. Large much-branched tree, with whitish bark on the young branches becoming dark-colored and rough on the mature parts: *lvs.* much like those of *P. grandidentata* in form, but smaller, usually thicker and more angular, the under surface—especially early in the season—woolly white, in shape from broadly ovate to orbicular, irregularly short-lobed or sinuate, short-truncate or somewhat cordate at base: catkins short (mostly about 2 in. long, the males longer), sessile, with thin dentate or erose scales; stamens 6-10; stigma linear-lobed. Eu. and

Asia.—The typical form of *P. alba* is less grown here than the varieties with lobed and very white-bottomed (and sometimes variegated) lvs. In old places and yards it is sometimes found, but var. *nivea* and in newer grounds var. *pyramidalis* are more frequent. Var. *globosa*, Spæth. Dense small tree or shrub, oval in outline of head: lvs. small, deltoid-cordate, slightly lobed, gray beneath and pinkish when young. Of horticultural origin. Var. *pendula*, Loud. Branchlets drooping. Var. *Richardii*, Hort. Lvs. yellow on upper surface.

Var. *nivea*, Wesm. (*P. nivea*, Willd. *P. argentea*, Hort. *P. arembergiana*, Hort.). This is the commonest form of white poplar in this country. It is known by the

3128. *Populus tremula* var. *pseudograndidentata*. ($\times \frac{1}{2}$)

snow-white under surfaces of its foliage and the 3- or 5-lobed maple-like lvs. It is far too frequent about old yards, where its inveterate brood of suckers make it a perpetual nuisance. It is sometimes called "silver maple," from the resemblance of its foliage to that of the maple. As a street tree in cities it is particularly offensive, for the cottony covering of the under side of the leaves and of the shoots holds soot and dust, and it looks repulsively dirty. Useful for foliage effects in large plantings.

Var. *subintegerrima*, Lange (*P. subintegerrima*, Dode. *P. monticola*, Brandegee. *P. Brandegeei*, Schneid.). Lvs. coriaceous, those on the long shoots ovate or orbicular, somewhat cordate or cuneate at base, nearly entire to somewhat toothed, white underneath; those on short shoots nearly circular, entire or slightly sinuate, gray underneath. Spain, N. Afr. Early intro. into Mex. and apparently naturalized in Low. Calif. G.F. 4:330; 6:190; 7:313 (descs.).

Var. *pyramidalis*, Bunge (*P. Bolleana*, Carr. *P. alba* var. *Bolleana*, Lauche). BOLLE'S POPLAR. Fig. 3126. A very tall narrow-topped tree, with cottony lvs. rather more deeply lobed (palmately 3-5-lobed) than those of var. *nivea*, those on the short shoots circular, coarsely triangular-toothed. The tree was intro. into Eu. from Asia in 1872 from Turkestan, and it was named for Dr. C. Bolle, an arboriculturist. It bears about the same relation to *P. alba* that the Lombardy poplar bears to *P. nigra*. Its fastigate habit, combined with the white foliage and shoots, makes it a most emphatic tree, and there is great danger of planting it too freely. It is said to be much attacked by borers.

2. *canescens*, Smith (*P. alba* var. *canescens*, Ait. *P. megalence*, Dode. *P. hybrida*, Reichb. *P. Steineriana*, Bornm.). GRAY POPLAR. Fig. 3126. Lvs. broad or nearly circular in general outline, prominently notched but not lobed, the under surfaces and the young shoots very gray-woolly, those on young or long shoots ovate-deltoid, cordate and acute, grayish tomentose beneath, the margin few-toothed and ciliate; those on short shoots nearly circular or broad-ovate, subcordate and obtuse, not ciliate, the lower surface light green. Var. *pendula*, Hort., is a fine form with pendulous

branches. This tree is met with occasionally. Its horticultural value is not greatly different from that of *P. alba* var. *nivea*. According to Elwes & Henry, *P. Bogueana*, Dode, is a vigorous form of this species in which the lvs. on long shoots are 5 in. or more in length and breadth; appears to be sold by some nurserymen abroad as *P. tomentosa*. Forms of this species are probably hybrids with *P. tremula*. Eu.

3. *tomentosa*, Carr. (*P. alba* var. *tomentosa*, Wesm. *P. alba* var. *denudata*, Maxim. *P. pekinensis*, L. Henry. *P. glabrata*, Dode). WHITE POPLAR of China. Large tree, similar to *P. alba*: lvs. thick, on long shoots of mature trees large (4-6 in. long), triangular-ovate, not lobed, the broad base truncate or subcordate, acuminate, margin sparingly sinuate-toothed, shining dark green above and glabrescent beneath; on short shoots small, ovate or triangular, cuneate, sinuate-toothed, glabrous beneath; on vigorous shoots white-tomentose beneath. N. China, where it makes a large tree, and is planted in temple gardens; the restless lvs. suggest the sound of falling rain. R.H. 1903, p. 355.—Hardy in Mass., but is said not to prop. from cuttings.

II. ASPENS. Lvs. not lobed, broader-based than ovate-form; mature lvs. green or at least not white-tomentose, glabrous or nearly so beneath, those on strong-growing and short shoots not prominently different; petiole usually distinctly flattened: terminal buds not large or glutinous: trees of small or intermediate stature, usually with trembling foliage.

4. *tremula*, Linn. EUROPEAN ASPEN. Fig. 3127. Open-headed light-lvd. tree, becoming 50-60 ft. tall, but mostly small and of relatively slow growth, producing suckers: lvs. small and thin, round-oval, more or less whitened beneath when young, bordered with deep and rounded incurved teeth; lf.-stalks long, slender and flattened, giving a restless motion to the foliage: lf.-buds small: catkins small, with hairy scales and stigma deeply divided; stamens usually 6-8. Widely distributed in Eu. and Asia, in this country known chiefly in its grafted weeping form (var. *pendula*, Hort.). The eastern Asiatic and Chinese form is made var. *Davidiana* by Schneider: always a slender tree, rarely exceeding about 60 ft.: young lvs. reddish purple and handsome as they unfold; suckers freely: there is a pubescent form of this variety.—The drooping form of the European aspen is perhaps the best weeping tree amongst the poplars. The spray is light, airy, and fountain-like, quite unlike the more common weeping forms of the native *P. grandidentata*, which present a stiff angular form, a combination that is rarely pleasing. A characteristic feature of this tree is the profusion of its very long catkins that appear in earliest spring, even before our native poplars are in bloom. The staminate or male catkins are particularly pleasing, and planters should choose that sex, if possible. Var. *pyramidalis*, Hort., is a slender pyramidal form. Var. *Frèynii*, Herv. Lvs. rhombic in outline, cuneate at base, ciliate, pubescent beneath when young. France, Germany. Var. *villösa*, Wesm. Hairy on young growths. Var. *pseudograndidentata*, Aschers. & Graebn., see description under No. 5. *P. adenöpada*,

3129. *Populus tremuloides*. ($\times \frac{1}{2}$)

Maxim. (*P. tremula* var. *adenopoda*, Burkill *P. Silvestrii*, Pampan.), is a recent Cent. Chinese species (allied to *P. tremula*) not in the trade: lvs. long-stalked, broad-ovate, long-acuminate, serrate, soft-pubescent at least on young trees, those on old mature trees closely crenate, greenish beneath. It is growing at the Arnold Arboretum and in the Rochester parks, where it is doing well.

5. *grandidentata*, Michx. LARGE-TOOTHED ASPEN. Tall straight tree, becoming 75 ft. high, with brittle wood and dull gray bark which with age is marked by plates but scarcely by ridges: lvs. roundish ovate, at the apex blunt or gradually narrowed and acute, with large irregular sinuate teeth, white-woolly when young but becoming glabrous: catkin-scales 5-6-divided: fr. slender, long-pedicelled. Distinguished from *P. tremula* by much larger and thicker lvs., which are bluish or rusty white beneath, more ovate in outline, with larger and more spreading teeth, stouter lf.-stalks and larger lf.-buds. Nova Scotia to Minn., Tenn., and N. C. S.S. 9:488.—The lf.-form is variable and botanical varieties have been made from them. In its normal or erect form it is rarely cult., but the weeping kinds, under a variety of names, are frequently seen. Most, and perhaps all, of these varieties originated in Eu., where the tree, like the cottonwood and the common aspen, were early intro. The winter twigs of the weeping varieties have a characteristic weak or zigzag growth. These weeping forms are very likely hybrids, sometimes distinguished as *P. tremula* var. *pseudograndidentata*, Aschers. & Graebn. (*P. pseudograndidentata*, Dode). Fig. 3128. Buds at maturity short, thick and somewhat viscid: lvs. much like those of *P. tremula* but larger, 3-4 in. diam., thicker, the margin with cartilaginous edge at maturity. The forms known as *P. græca pendula* and Parasol de St. Julien are by some referred to *P. tremuloides*, but these names have been applied in this country at least to plants of the above series. The *P. græca* of authors is confused. *P. grandidentata* is a common tree in the E. U. S., growing under a variety of conditions, as on dryish banks and slopes and near swamps and streams.

6. *tremuloides*, Michx. AMERICAN ASPEN. Fig. 3129. Small weak tree, abundant northward and springing up in clearings: lvs. small, roundish ovate with a slightly tapering or a truncate or sometimes even a semi-cordate base, abruptly contracted to a short usually apiculate point, finely crenate-serrate, downy when young but becoming smooth on both surfaces, the petioles long and slender so that the foliage twinkles in the slightest breeze: catkins drooping, with silky deeply 3-5-cleft scales or bracts, the pistillate becoming 3-4 in. long: caps. oblong-conical, not hairy or pubescent: the species is very like *P. tremula*, but the lvs. are

3130. Staminate catkins of an aspen. (X 1/2)

usually less circular and more abruptly acuminate, the margins are small-crenate rather than deeply toothed, and the lvs. are green on the under side. Generally distributed in N. Amer., north of Pa., and Ky., and extending to Mex. in the mountains. S.S. 9:487.—The bark of the young trees is whitish gray, rendering the saplings very conspicuous in a coppice. In woods the tree is said sometimes to reach a height of 100 ft., but it is usually much smaller than this.

The far western form has been separated as var. *aurea*, Daniels (*P. aurea*, Tidest.). Several lf.-varieties have been described.

Var. *pendula*, Schneid., is a drooping or weeping form. *P. cercidiphylla*, Brit., is a form or a closely related species in Wyoming with small entire or undulate lvs. which bear a peculiar concave gland on the blade on either side of the petiole attachment. *P. atheniensis* is an old name said to have been given from a N.

American Athens, and as it is a very early name it is used by Koch in place of *P. tremuloides*. The *P. græca*, of some authors perhaps applies to this species through some error; see No. 5. The name *P. græca* appears to have originated with Aiton, who apparently gave the name because he found it cult. as the "Athenian poplar;" it is probably the same as *P. atheniensis*, Ludw.

7. *Sieboldii*, Miq. Fig. 3131. Tree, 20-30 ft., of spreading habit, suckering freely, with rather dark and heavy foliage: lvs. large, round-ovate, with a short triangular subacute apex, at the base truncate or gradually narrowed into a short petiole, dentate-serrate, with shallow glandular-incurved teeth, more or less whitened beneath. Japan; the wood used for matches and the tree less abundant than formerly.—Hardy in W. N. Y. Said by Wilson to be a tree of medium size in Japan, very like *P. tremula* in general appearance, and suckers freely. *P. rotundifolia*, Griff. (*P. microcarpa*, Hook. f.), is very similar, but the lvs. of old branches are more or less cordate at base: lvs. 3-4 in. across, long-petioled, orbicular, sinuate: fruiting catkins 3-5 in. long and very slender with a tomentose rachis: caps. only 1/4 in. long, with a very short pedicel. Himalaya region; probably not in cult. in this country. *P. rotundifolia* var. *Duclosiana*, Gombocz. (*P. Duclosiana*, Dode. *P. macranthela*, Lev.), of S. W. China, has still longer fruiting catkins (6-10 in. long) and longer-pedicelled caps.

3131. *Populus Sieboldii*. (X 1/2)

III. BLACK POPLARS AND COTTONWOODS. Lvs. not lobed, mostly wider and broader-based than ovate in form; mature lvs. hard or firm in texture, green on both surfaces, mostly with a clearly marked translucent or hyaline edge (which may appear as a thin indurated line in the dried specimen); petiole commonly flattened, at least toward the blade: terminal buds medium-large and more or less viscid, but not markedly odorous: mostly large trees.

A. Lf.-margins not ciliate.

8. *nigra*, Linn. BLACK POPLAR. Tree of medium to large size, with smooth twigs and lvs. somewhat resembling those of the cottonwood, but generally smaller and much less deeply toothed, longer in proportion to their width and often with a tapering or rounded base, with no cilia or hairs on margin and no basal glands; lf.-stalk much flattened, so that the foliage moves freely in the wind: stamens 12-25; stigmas and

placentæ 2. Eu., Siberia.—The tree usually has a pyramidal habit of growth and a dark cast to the foliage. It is a less lustrous tree than the cottonwood and grows more slowly. Var. *betulifolia*, Torr. (*P. betulifolia*, Pursh. *P. hudsónica*, Michx. *P. nigra* var. *hudsónica*, Schneid.), has the young growth and the petioles downy. B.M. 8298. Specimens of this plant were found along the Hudson by Michaux, who thought it an American species and published it early in the century as *Populus hudsonica*. Pursh, in 1814, published it again as the "birch-leaved poplar," *Populus betulifolia*, from trees found near Lake Ontario. Although it was found half wild in N. Y. about a century ago, it does not appear to have increased itself in Amer., and the variety is probably of European origin. *P. nigra* is rarely seen, even in cult. grounds. It is sometimes spontaneous in the E. Variable in cult. and grown in European collections under a variety of names. With the exception of var. *italica*, these forms are little known in this country. *P. vistulensis*, Dode, is a form of moderately strong growth; branches spreading; lvs. rhomboidal, dark green. The two main forms or types of the black poplar are the glabrous or smooth (var. *typica*, Schneid.), S. Eu., and the pubescent (var. *betulifolia*). The English or downy black poplar makes a wide-spreading attractive large tree, and forms great burs on its trunk. Var. *élegans*, Bailey (*P. elegans* of nurserymen, and probably some one of the well-known European forms), is a tree of pronounced strict or pyramidal habit, but considerably broader than the Lombardy poplar, with thinly pubescent twigs and petioles; foliage small and light-colored and very versatile in a breeze, with a handsome reddish tint to the lf.-stalks and young shoots. It is worth growing in every well-kept place, especially if placed against a planting of heavier foliage. *Populus canescens* of some American nurserymen (not of botanists) is very like this, although it has less color and brightness. *P. charkowiensis*, Schroed., is probably a hybrid in this group, by some supposed to be Lombardy poplar $\times$ *P. nigra*; apparently allied to *P. Eugenei*. Var. *Viadri*, Aschers. & Graebn. Tree narrow-pyramidal with ascending branches; lvs. like those of *P. nigra* but more cuspidate. *P. afghánica*, Schneid. (*P. nigra* var. *afghánica*, Aitch. & Hemsl.), of Afghanistan, has exceedingly slender branches and very small lvs. Not in cult. in this country.

3132. *Populus nigra* var. *italica*.—
The Lombardy poplar. ($\times \frac{1}{2}$)

Var. *italica*, Du Roi (var. *pyramidalis*, Spach. *P. italica*, Moench. *P. dilatata*, Ait. *P. fastigiata*, Poir. *P. pyramidalis*, Borkh. *P. pyramidata*, Moench. *P. sinensis*, Dode). LOMBARDY OR ITALIAN POPLAR. Figs. 3132, 3133. Differs from the typical black poplar (*P. nigra*) in its tall narrow growth, glabrous young shoots, a confirmed habit of suckering from the root and generally a more tapering base to the lvs.: buds small: lower branches of the head taking a strong upward direction so that it has no hanging or drooping spray; holds its green foliage late in autumn. It is a staminate sport from *P. nigra* var. *typica*, originating in the plains of Lombardy about 1700–20 and now widely spread over the world by means of cuttings. Pistillate Lombardies have been reported but they are of different origin and are usually broader-headed trees. With age, the Lombardy poplar becomes one of the most striking and picturesque trees, particularly when some of the sprouts are allowed to grow about the old stock, as in Fig. 3133. In the northernmost states it is not long-lived. *P. thevestina*, Dode, from Morocco, is apparently a form of the Lombardy poplar type with whitish or gray bark; tree very large; lvs. very large, almost triangular, toothed, shining, with carmine petioles.

3133. An old clump of Lombardy poplar.

Var. *plantierensis*, Schneid. (*P. plantierensis*, Dode). Similar to Lombardy poplar but with reddish pubescent petioles and short-pubescent branchlets. Of horticultural origin, in the nursery of Simon-Louis at Plantières, near Metz, France. This is the fastigiate form of *P. nigra* var. *betulifolia*; probably not in commerce in this country. Both sexes are known.

AA. Lf.-margins more or less distinctly ciliate.

9. *Fremontii*, Wats. WESTERN COTTONWOOD. Large tree with trunk sometimes 5–6 ft. diam., very large head of stout spreading somewhat pendulous branches, and bark on mature trunks deeply and broadly ridged; lvs. deltoid or roundish (on young shoots reniform or rhombic), broader than long, with a broad acute apex or sometimes even rounded at apex, cuneate or truncate at base, coarsely irregularly serrate with incurved gland-tipped teeth, thick, firm and shining at maturity, 2–3 in. long; petiole to $2\frac{1}{2}$ in. long and often pubescent; glands absent at base of lf.: catkins $1\frac{1}{2}$ –4 in. long, the pistillate fls. on short pedicels and with thin brown filiform-lobed scales; stamens 50–70; caps. ovate, to $1\frac{1}{2}$ in. long. Banks of streams. W. Texas, S. Colo., Utah, Nev., Calif. S.S. 9:496.

10. *Wislizenii*, Sarg. (*P. Fremontii* var. (?) *Wislizenii*, Wats.). VALLEY COTTONWOOD of the Rio Grande Valley, W. Texas, New Mex., and adjacent parts of Mex., differing in having slender-pedicelled pistillate fls.: lvs. deltoid, sharply acuminate, truncate or slightly cuneate at base; pistillate catkins very slender (2–6 in. long). S.S. 14:732.—A similar tree of Mex., where it is also often planted for shade (and to be looked for in

New Mex., Ariz. and S. Calif.), is *P. mexicana*, Wesm. (*P. MacDougalii*, Rose): a tall tree, sometimes 80 ft.: lvs. longer-pointed, the petioles not flattened: fls. shorter-stalked than in *P. Wislizenii* and longer than in *P. Fremontii*: caps. $\frac{1}{4}$ – $\frac{1}{2}$ in. long: it is closely related to *P. Fremontii*, differing chiefly in the larger disk of

the pistillate fls., in the rhombic lvs. of the young shoots and which often appear with the deltoid lvs. on old shoots. S.S. 14:71.

11. *deltoides*, Marsh. (*P. deltoides*, Auth.). SOUTHERN COTTONWOOD. CAROLINA POPLAR. Large native tree with deeply furrowed or ridged dark-colored or gray-

brown bark in mature specimens, and a deliquescent habit (top breaking up into many strong branches of about equal importance), the branches wide-spreading and the top relatively thin and open: branchlets usually terete except on very strong shoots: lvs. large, triangular-ovate, very broad in proportion to their length, mostly truncate or nearly straight on the base, abruptly acuminate, coarsely crenate-dentate with mostly curved sinuses, but the margin plane or flat, the petiole long, much flattened near the blade and commonly with 2 or 3 glands at the top, the stipules small and falling early: catkins long and loosely fld., the scales large, dilated at apex and filiform-lobed; stamens 40–60; stigmas and placenta 3 or 4: fr. an ovoid acute caps. Generally distributed from Que. to the plains region and south to Md. and possibly farther. S.S. 9:494, 495.—A variable group; although familiarly known, the specific characters are not clearly defined. The species takes on somewhat unlike forms in the S. and N. and W. Marshall meant to designate the southern form, which has the following characters (*P. deltoides* var. *missouriensis*, Henry. *P. angulata*, Auth., not Ait. *P. deltoides* var. *angulata*, Sarg.): twigs angled: lvs. deltoid-ovate, 5–6 in. wide and about the same length, at the base shallowly cordate or truncate, at the apex short-acuminate and cuspidate, when young and even to midsummer pubescent on both surfaces and petiole; margins sinuate-dentate, the teeth few and coarse and with incurved tips; basal glands 3 or 4. S. E. U. S. and in the Mississippi Valley, from Mo. southward.

Var. *monilifera*, Henry (as *P. deltoides* var. *monilifera*. *P. monilifera*, Ait.). NORTHERN COTTONWOOD. Figs. 3134–3137. Twigs usually not angled: lvs. smaller, on average normal shoots about 3–4 in. wide and of similar length, glabrous on both surfaces and petiole (or only a few evanescent hairs along midrib

and nerves), the basal glands usually 2. Canada to Pa. and probably farther south.

Some of the cult. forms of this group are fairly distinct in foliage and aspect, and they appear to be associated with particular horticultural names in the nurseries. A golden-lvd. tree is known as var. *Van Geertii* or var. *aurea* (really a form of *P. serotina*). This is one of the best of yellow-lvd. trees, and generally holds its color throughout the season. Like all trees of this unusual character, it should be used cautiously, and the best effects are obtained when it is planted against a group of trees so as to appear as if naturally projecting from the other foliage. Some of the most ornamental specimens of cottonwood are those with reddish lf.-stalks and midribs. Taking all things into consideration, the cottonwood is one of the best of the poplars for general ornamental planting. It grows rapidly and in almost every soil, and yet it possesses elements of strength and durability which most of the poplars lack. Its foliage is always bright and glossy, and the constant movement of the broad rich green lvs. gives it an air of cheeriness which few trees possess.

This tree or *P. Sargentii* has been much used on the prairies and in western towns, much too abundantly for good landscape effects. The rapid growth of the tree gives a feeling of luxuriance to plantations even when most other trees appear to be weak or starved. The cottonwood thrives best on rather low lands, and yet it is generally an admirable tree for high and drier areas. Spontaneous forms of introduced hybrids have probably been confused with *P. deltoides*, obscuring the definition of the species, as, particularly, *P. Eugenei* and *P. angulata*.

A poplar in Mont. and Idaho allied to this species has been provisionally referred to *P. Besseyana*, Dode (Bull. Torr. Club, 39:302). The lf.-bases are rounded or subcuneate and more or less serrate; glands small; petioles flattened. "In *P. Sargentii*, the lvs. are flabelate-cordate, with an open concave sinus at base, which is toothless. The lvs. much resemble *P. acuminata* but are broader and less cuneate at the base, and in the latter species the petioles are terete." It is probable, however, that *P. Besseyana*, Dode, is *P. angulata*, Ait.

12. *Sargentii*, Dode (*P. deltoides* var. *occidentalis*, Rydb. *P. occidentalis*, Brit. *P. monilifera* var. *occidentalis*, Henry). GREAT PLAINS COTTONWOOD. Lvs. usually smaller and with relatively longer abrupt acumination, broader at base and with fewer rather coarser teeth: young branches light yellow, shining: buds often pubescent: pedicels shorter than the caps. The Great Plains or xerophytic form, Neb. to Dak., Sask., Alberta and to New Mex.; frequent along stream-beds. S.T.S. 2:583.—Doubtfully specifically separable from *P. deltoides*.

(a) *P. Andrewsii*, Sarg. (*P. acuminata* $\times$ *P. Sargentii*). Raised by E. H. Andrews, Colo., from a cutting taken from a wild tree: lvs. oblong-ovate, gradually or abruptly long-pointed and acuminate, rounded or occasionally abruptly cuneate at the broad base, finely serrate except at apex, thin, bright green and shining above and

rather paler below; petiole nearly terete; branchlets light orange-brown; winter-buds acuminate, resinous.

13. *angulata*, Ait. HYBRID CAROLINA POPLAR. Fig. 3138. For more than a century considered to be a native tree in the S., although by most botanists not clearly separated from *P. deltoides*, but Aiton's original specimens are interpreted by Henry to represent a hybrid of *P. deltoides* and *P. nigra* var. *typica*; similar forms are known in Europe and are planted in this country: known in both sexes; strong-growing tree with mostly prominently ridged or angled branchlets: lvs. triangular-ovate, always longer than broad, at the base truncate or more or less cordate, at the apex acute or short-acuminate, at maturity glabrous and firm in texture but slightly pubescent when young, glands 2-6 at base of blade or on apex of petiole, the margin except at apex with narrow translucent border, crenate-glandular and ciliate with the teeth close together; petiole flattened: catkins 2-3 in. long, with small cucullate or concave-dentate (not filiform-lobed) scales; stamens 30-40. Henry suggested that the floral characters (as seen in Aiton's type) may be a mutation under European conditions, inasmuch as catkins with the scales of the species described by Aiton appear not to have been identified from the wild in N. Amer., but later he has proposed the hypothesis of the hybrid origin and this seems to go far toward clearing up the difficulties of this perplexing group. The tree is still recognized as cult. in England and France, where it was known as early as 1750. In general, the longer-than-broad lvs. which are merely acute or short-acuminate rather than long-acuminate, and with deeply cordate or truncate base, distinguish this form. It is a loose open grower, with nothing of the strict narrow shape of the common Carolina poplar of the streets, which is probably *P. Eugenei*. It is hardy in N. Y. How extensively *P. angulata* occurs as a planted tree in N. Amer. should be made a subject of inquiry.

14. *Eugenei*, Simon-Louis. EUGENE POPLAR. Figs. 3139-3141, but known apparently to horticulturists as Carolina poplar: strict-growing strong staminate tree mostly with a markedly excurrent trunk (st. or bole continuing through the top or head) and with many strongly ascending branches, making the top narrow and almost columnar or pyramidal and densely foliated, but with more or less hanging small spray on the under side or bottom of the head, the tree shedding its branchlets or little twigs freely: lvs. mostly triangular-ovate (broadest below the middle) and long-acuminate-pointed, truncate or slightly cuneate-truncate at base, crenate-serrate with close mostly incurved teeth, petioles flattened: autumn buds long, only slightly viscid, those in the upper axils slender and often curved-pointed.—This interesting and valuable rapid-

growing poplar was found in 1832 as a chance seedling in the Simon-Louis nursery, near Metz, France; it is supposed to be a hybrid between Lombardy poplar (male) and *P. regenerata* (female) and it has the marks of the two. It is now one of the horticultural poplars and is often confounded with the native cottonwood. Henry writes that the original tree is, in his opinion, "the

3138. The longer-than-broad leaves of *Populus angulata*. ($\times \frac{1}{2}$)

most wonderful tree in Europe in point of vigor, as it measured in 1913, when 81 years old, no less than 150 ft. in height and 25 ft. in girth at 5 ft. above the ground, and appears to be still growing rapidly. Another tree, a cutting of the last, planted in 1870, was 140 ft. high by 15 ft. in girth." Some of the tall Carolina poplars planted in the eastern parts appear to be *P. Eugenei*, or a very similar hybrid.

In this account, the poplars of this group in E. N. Amer. (east of the Mississippi) are assumed to be of a single species, *P. deltoides*, and what has been thought to be *P. angulata* of the southern states is taken as the type of the species, and the true *P. angulata* is considered to be a hybrid that is more or less planted. Whether other species are involved is to be determined by much further study of the unquestioned native forms. It is not unlikely that there are unrecognized natural hybrids. Tidestrom considers that there are 3 species in Maryland, *P. virginiana*, *P. deltoides*, and *P. angulata* (Rhodora, xvi. 208, 1914). The lf.-forms in cult. are very confusing if one desires to find separable types without numberless intermediates. Taken in a broader sense, *P. deltoides* may be considered to range through the country east of the Rocky Mts., being represented in the S. by the type form, and in the W. by var. *occidentalis* (*P. Sargentii*). In a still wider sense, *P. Fremontii* and *P. Wislizenii* may be regarded as geographical forms.

Very recently, A. Henry has distinguished 3 forms of the eastern cottonwood, and has taken up the name *P. deltoides* although not certain as to the original application of it. The 3 forms are: (1) *P. deltoides* var. *monilifera*, Henry (*P. monilifera*, Ait.), the form of the northeastern country: lvs. deltoid-ovate, about 3 in. long and wide, abruptly contracted into a long non-serrated apex, the base wide and shallowly cordate, bearing 2 glands at the junction with the petiole in front, the margin densely ciliate, both surfaces and petiole glabrous except for a few evanescent hairs on midrib and main nerves. G.C. III. 56:4 (tree in winter). (2) *P. deltoides* var. *occidentalis*, Rydb. (See *P. Sargentii*, No. 12). (3) *P. deltoides* var. *missouriensis*, Henry (*P. angulata* var. *missouriensis*, Henry). Lvs. similar in shape to those of var. *monilifera* but larger, being 5 or 6 in. wide and long, both surfaces and the petiole pubescent with some of the pubescence remaining in summer, the basal glands 3 or 4. La. to Mo., also in Ga.

The botanical names of these native poplars are confused. If it is assumed that there is only one species in this group, then we may apply to it the name *P. deltoides*, modified from Marshall, 1785, or *P. canadensis*, Moench, 1785; but the descriptions under these names are not sufficient to designate the species if we undertake to define them closely. *P. virginiana*, Foug., and *P. carolinensis*, Moench, are undeterminable from the descriptions. There is every probability that Marshall in his "Arbustum Americanum" (1785) meant to designate the Carolina poplar by his *P. deltoides*

3137. Eastern cottonwood, *Populus deltoides* var. *monilifera*. —The Lafayette tree at Geneva, N. Y., named for General Lafayette, and one of the largest trees in the state.

(which has recently been taken up by botanists under the forms *deltoides* and *deltoides*). Koch, in his *Dendrologie*, however, suggests *P. grandidentata* as the species meant by Marshall, but the range of this species forbids. The full account in Marshall is as follows:

"*Populus deltoide*. White Poplar,
or Cotton Tree of
Carolina

"(Bartram's Catalogue).

"This becomes a tall tree, with a large erect trunk, covered with a white, smoothish bark, resembling that of the Aspen tree. The leaves are large, generally nearly triangular, toothed or indented with sharp and deep serratures, of a shining full green on their upper surface, but somewhat lighter or hoary underneath; standing upon long slender footstalks, and generally restless or in motion.

The timber is white, firm, and elastic, principally used for fence-rails. It grows naturally upon rich low lands, on the banks of large rivers in Carolina and Florida."

3139. Leaves of one of the tall, narrow Carolina poplars, presumably *P. Eugenei* ($\times \frac{1}{2}$), from which the description under No. 14 is partly drawn.

The first undisputed binomials, reinforced by specimens, appear to be those of Aiton, 1789, *P. monilifera* and *P. angulata*. It is unfortunate that Marshall's *P. deltoide* has been revived in order to satisfy the demand for priority; it is not Latin; it may be rendered either in the form *deltoides* or *deltoides*, thereby introducing confusion; the only way of determining what plant he had in mind is by habitat and range,—"rich lowlands" "in Carolina and Florida." As we now define the poplars of Carolina and Florida there is only one species, but it is not unlikely that others will be separated. Marshall's name, as the other very early names, should be disregarded and Aiton's *P. monilifera* taken as the starting-point. The name *P. canadensis* has been variously applied by succeeding authors; it is probably a female hybrid; at least some of the stock once grown in N. Amer. under this name was *P. deltoide*: the name should be discarded. *P. virginiana*, Foug., 1786, is fairly well defined by Castiglioni (*Viaggio Negli Stati Uni* . . . pub. at Milano, 1790), and appears to be the species named *P. monilifera* by Aiton, 1789, but to take up the name would contribute nothing to clarity.

The Carolina poplar was early planted in this country. It was apparently known to John Bartram. It is mentioned by M' Mahon in his "Gardener's Calendar," 1806. It is listed in the catalogue of William Booth, of Baltimore, 1810; also by William Prince of Flushing, Long Island, in 1823, 1825, 1829, by Landreth, of Philadelphia, in 1828. What form of poplar all these early planters had is not now to be determined. To what extent the hybrid Carolina poplar (*P. angulata*) is now planted in this country is unknown to the writer. It is apparent that European hybrid poplars are useful here and they have been intro. from time to time. The prevailing "Carolina poplar" of present planting in the northeastern states is probably *P. Eugenei*, but others may be involved. The binomials that have been applied more or less loosely or erroneously to the *P. angulata* group on the supposition that it is a species of the S. U. S. are as follows: *P. angulosa*, *P. macrophylla*, *P. deltoidea* var. *angulata*, *P. carolina*, *P. caroliniana*, and *P. carolinensis*, Hort.; *P. deltoide* var. *carolinensis*, Bailey; *P. deltoide* var. *missouriensis*,

Henry. If *P. deltoide* is itself taken to be this southern form, then all these synonyms must now be ranged under that name, so far as they may apply to the plant in question.

Supposed or accepted hybrids in the black poplar group (*P. nigra*-*deltoides*-*angulata*) are recognized as follows (only two or three of which are likely to be found in this country unless in special collections):

(a) *P. serotina*, Hartig (*P. helvética*, Poed. *P. angulata* var. *serotina*, Koehne). BLACK ITALIAN POPLAR. SWISS POPLAR in France. A valuable timber tree: very strong staminate tree with a broad head and wide-spreading but ascending branches and regularly furrowed bark: buds brownish and viscid: lvs. appearing very late (hence the name *P. serotina*), reddish tinged and glabrous, larger than those of *P. Eugenei*, ovate-deltoid with broad truncate base and short cuspidate or acuminate apex, with few crenate serrations rather far apart and toward the base of the blade, the glands 1, 2 or 0, near the apex of the reddish petiole: young plants and vigorous growths with ridged shoots, and lvs. 5-6 in. or more long. G.C. III. 56:47.—A very old hybrid, having been described by Duhamel in 1755. *P. deltoide* var. *monilifera* is probably one of the parents, and *P. nigra* var. *typica* the other. Very likely one of the planted poplars in this country and apparently sometimes passing as *P. deltoide*.

(b) *P. marilandica*, Bosc (*P. eurylon*, Dode). Pistillate tree that originated early in the 19th century: buds small and viscid: lvs. (resembling those of *P. nigra*) 4 x 3 in., rhomboid, cuneate at base, tapering above into a long-acuminate apex, glabrous, crenate-serrate with incurved teeth, the margins with minute scattered hairs. Appears to be a hybrid of *P. deltoide* var. *monilifera* and *P. nigra*.

(c) *P. Henryana*, Dode. Of unknown origin: of branching open habit similar to that of *P. deltoide* var. *monilifera*: a staminate tree, with lvs. cuneate at broad base: "of no particular vigor," and little known. G. III. 56:46.

(d) *P. robusta*, Schneid. Probably the issue of *P. angulata* x *P. plantierensis*: of narrow columnar habit but short branches much more divaricate than in the Lombardy, of very rapid growth: twigs hairy: staminate. G.C. III. 56:66.

(e) *P. regenerata*, Schneid. (*P. Eucalyptus*, Hort.). Pistillate tree like *P. serotina* in twigs and foliage but lvs. opening 2 weeks or more earlier, of narrow outline and bearing pistillate fls.: catkins similar to those of *P. marilandica*, but with usually only 2 stigmas.

(f) *P. Lloydii*, Henry (probably *P. nigra* var. *betulifolia* and *P. serotina*). Tall pistillate tree with pubescent branchlets, described by Henry as follows: Bark similar to that of *P. serotina*: young branchlets with minute pubescence, glabrous and yellowish brown the second year; buds small, viscid: lvs. about 2½ in. wide and long, truncate, rounded or cuneate at base, with a short non-serrated, acuminate or cuspidate apex, crenate-serrate, teeth incurved-ciliate till late summer; glands minute, often absent; petiole reddish with minute pubescence: pistillate catkins 2-2½ in., glabrous; pedicels short, ovary globose, in a cup-shaped oblique entire disk with 2, rarely 3, dilated spreading stigmas: fruiting catkins 4 in.; caps. 2-valved. G.C. III. 56:67.

(g) *P. generosa*, Henry. Intermediate between the parents (*P. angulata*, pistillate, and *P. trichocarpa*) in width and color of lvs., the under surface pale gray; resembles *P. angulata* in having coarsely serrate often cordate translucent-bordered lvs., but *P. trichocarpa* in bearing rounded petioles. A plant of "astounding vigor," issued from a cross made at Kew in March, 1912. G.C. III. 56:258, 259. See also Henry, Trans. Roy. Scott. Arbor. Soc. 30, p. 25, fig. 10; and Journ. Dept. Agric. Ireland, 15:44.—A tree of much promise. It originated from hand-pollination, *P. trichocarpa* furnishing the pollen, four seedlings resulting.

3140. Winter buds of Populus No. 14. ($\times \frac{1}{2}$)

3141. The tree commonly known as Carolina poplar. Probably *Populus Eugenei*.

IV. **HEAVY or LARGE-LEAVED POPLARS or COTTONWOODS.** *Lvs. large and broad, rounded or cordate rather than truncate at base, not lobed, the petiole cylindrical or channelled, not flat, more or less pubescent but becoming mostly glabrous at least above: terminal buds medium to large size, more or less glutinous but scarcely balsamic: trees, mostly of good size.*

15. *lasiocarpa*, Oliver (*P. Fargesii*, Franch.). Tree, 50–60 ft., with angular stout more or less pubescent young shoots and large viscid buds: *lvs.* very large (often 10–14 in. long and 8–9 in. wide), ovate or broad-oblong, acute or short-acuminate, evenly glandular-crenate-serrate, red-veined, deeply cordate at base and biglandular, more or less tomentose beneath but becoming glabrous above; petiole nearly cylindrical, red; stipules oblong-lanceolate: catkins 4–6 in. long or longer in fruit, the polygamous fls. short-pedicelled; bracts ovate or obovate, finely lacinate; stamens 23 or more in the male fls. and 3–6 in the hermaphrodite fls.: caps. ovoid and densely woolly, to $\frac{1}{2}$ in. long. China, common at 4,000–6,000 ft. B.M. 8625. R.H. 1911, p. 565. R.B. 35, p. 312. G.M. 51:763.—*P. Wilsonii*, Schneid., is a rare tree in W. China, with a pyramidal or columnar head of short spreading branches and strikingly handsome dark bluish green paper-like broad-ovate or roundish or broadly ovate-oblong more or less cordate-based and obtuse *lvs.* which are less deeply cordate than those of *P. lasiocarpa*, and less broadly oblong; it is also distinguished by its habit, the glabrous and purple rather than tomentose and yellowish branchlets, and the *lvs.* bluish green above and rather whitish gray beneath.

16. *heterophylla*, Linn. **SWAMP or BLACK COTTONWOOD. DOWNY POPLAR.** A swamp species of irregular branching habit, only rarely planted, reaching 80 ft. and diam. of trunk of 3 ft.: *lvs.* densely tomentose when young, but becoming glabrous with age or remaining floccose beneath, 4–7 in. long, broad-ovate in outline, obtuse or somewhat acute at apex, more or less

3142.
Populus balsamifera.
($\times \frac{1}{4}$)

truncate or subcordate or rounded at base, serrate, the petiole terete and tomentose or nearly glabrous: staminate catkins stout but rather short, stamens 12–20 and scales filiform-lobed; pistillate catkins slender but rather short, becoming erect or spreading: caps. ovoid-acute, on slender pedicels. Conn. to Ga., La., Ark. and S. Mo.; near the coast in the northern states. S.S. 9:489.

V. **BALSAM POPLARS. TACAMAHAC.** *Lvs. not lobed, varying from broad-ovate to narrower; mature lvs. whitish but not cottony-tomentose beneath, not clearly translucent-edged; petioles cylindrical or 4-angled, mostly grooved on upper side: terminal buds large to very large, very viscid and balsamic in odor: mostly large trees.*

A. *Branchlets terete, without projecting ridges or ribs (except sometimes on strong young shoots).*

B. *Petioles and branchlets mostly glabrous.*

17. *balsamifera*, Linn. **BALSAM POPLAR. TACAMAHAC.** Figs. 3142, 3143. Tall upright tree, with a narrow top and glabrous twigs: *lvs.* thick and firm, erect, whitened beneath, usually smaller than in most poplars of this group, glabrous except that petioles are slightly pubescent, ovate-lanceolate or oval, tapering toward the top and obtuse or narrowly rounded at base, finely and obtusely toothed: catkins drooping, slender but rather densely fld., appearing in very early spring; ovary 2-carpelled: caps. pedicelled. Mackenzie River to Newfoundland and to Brit. Col., southward in the northern tier of states; not in Asia. S.S. 9:490. Var. *Michauxii*, Henry (*P. Michauxii*, Dode. *P. canadensis*, Amer. Auth. in part, not Ait.), is a form with slightly cordate or rounded-based ovate *lvs.* and slightly pubescent on petioles, veins beneath and twigs. G.C. III. 59:230.—The native *P. balsamifera* is sometimes seen about farm buildings and roadsides, where it makes a durable and interesting tree. The dull whiteness of the under side of the leaves affords a pleasant variety and contrast in its foliage, and the fragrance of the resinous buds in spring is agreeable to most persons. It is a desirable tree for occasional planting, but, like the Lombardy, it generally appears to best advantage when placed amongst other trees. It is a hardier tree than the Lombardy, and does not run quickly to such extravagant heights. In cult., it seems to present a variety of forms or else enters into a number of hybrids. The true *P. balsamifera* is said to be rare in cult. in Cent. Eu., and only in the male sex.

In Mont. and Idaho is a balsam poplar with sessile 3-carpelled caps., as in *P. trichocarpa*, although differing in other fr. characters from that species: *lvs.* usually broader than in *P. balsamifera* and often subcordate, glabrous. This form Rydberg considers to be *P. hastata*, Dode.

In the Himalayan region, *P. ciliata*, Wall., belongs to this group, but it is probably not in cult. in this country: *lvs.* ovate or ovate-cordate, acuminate, glabrous except for the gland-ciliate unequal teeth, the base 3-nerved: a large tree, with *lvs.* 3–7 in. long.

18. *fortissima*, Nels. & Macbr. (*P. angustifolia*, James, not Weinm. *P. balsamifera* var. *angustifolia*, Wats.). Fig. 3144. **NARROW-LEAVED COTTONWOOD.** Small pyramidal or conical tree (reaching 60 ft. in the wild), with slender twigs and small buds, and soft clear green foliage: bark rough-furrowed: *lvs.* small for the genus, lanceolate or ovate-lanceolate, short-stalked, green on both surfaces, finely and evenly serrate: catkins short, densely fld.: ovary somewhat 2-lobed. Interior region from Assiniboia to Neb. and Ariz., and westward; common along mountain streams at middle altitudes in the Rocky Mts. S.S. 9:492.—Common street tree in parts of the W. and sometimes planted in the E. for ornament.

3143.
Winter buds
of *Populus*
balsamifera.
($\times \frac{1}{2}$)

19. *acuminata*, Rydb. (*P. coloradensis*, Dode).
SMOOTH-BARKED COTTONWOOD.

Tree slender, with smoother and lighter-colored bark than in *P. fortissima*: lvs. long-petioled, rhomboid-lanceolate, acuminate, serrate only at the middle; pistillate catkins slender. Eastern slopes of Rocky Mts.—A well-shaped and attractive tree in cult., the lvs. long-acuminate and somewhat drooping.

P. Tweedyi, Brit., is allied to this species and perhaps a variant of it, with mature lvs. broadly ovate or some of them even orbicular, and cordate at base. Wyo.

BB. Petioles and branchlets mostly pubescent (becoming glabrate at full maturity).

20. *candicans*, Ait. (*P. Tacamahaca*, Mill. *P. ontariensis*, Desf. *P. balsamifera* var. *candicans*, Gray. *P. macrophylla*, Hort.). BALM OF GILEAD. ONTARIO POPLAR.

Strong-growing spreading pistillate tree, much planted in Eu. as "the balsam poplar" and esteemed for its vigor and hardiness and the resinous fragrance of its large buds in springtime: lvs. broad and

heart-shaped, very hairy (as are also the twigs), the lf.-stalk usually hairy and somewhat flattened. G.C. III. 59:230. Apparently a hybrid, the origin of which is in doubt; the native tree usually confused with this is *P. balsamifera* var. *Michauxii*, and sometimes also the supposed hybrid, *P. Jackii*.—Said to be sometimes grown under the names of *P. suaveolens* and *P. balsamifera*. It is very different from the balsam poplar in method of growth, as it has none of the pyramidal or spire-like tendency of that species, but usually makes a broad and irregularly spreading top. The Balm of Gilead makes a good street tree, and is perhaps the best of the older poplars for shade, but it is not known how extensively it is planted in N. Amer.; it is probably of European origin. Well-grown trees of the form passing under this name in the U. S. have the darkest and richest foliage of any common poplar, and this character makes the tree valuable in heavy groups about the borders of a place. The top is liable to become open and broken with age, however, and the tree often sprouts profusely. It is not well adapted to smoky and dusty locations, as it soon becomes grimy.

21. *Jackii*, Sarg. (*P. Baileyana*, Henry). Fig. 3145. A supposed hybrid of *P. deltoides* var. *monilifera* and *P. balsamifera*, found as if native in Mich. and Que.: intermediate between the two parents, with terete glabrous twigs: lvs. large, broad-ovate, cordate at base, biglandular, slender-acuminate, the margin with scattered deciduous hairs and a translucent border, the under surface pale but scarcely whitish, the petioles channeled but not compressed, 4-angled in cross-section. G.C. III. 59:231.—The buds are less viscid than those of *P. balsamifera*, and the leaf-serratures are not so sharp. It makes a broad-headed branching tree. The range of this tree is not known.

22. *tristis*, Fisch. Small tree with viscid pubescent buds which are often attended by persistent ovate-acuminate stipules: lvs. narrowly ovate, 4 in. long and one-half as broad, ciliate, acuminate, subcordate or rounded at base. Cent. Asia, Himalaya.

23. *Maximowiczii*, Henry. JAPAN POPLAR. Very large tree, to 100 ft., and 3-4 ft. diam., with densely pubescent pale brown branchlets: lvs. about 4 in. long, nearly orbicular, oval or broad-elliptic, broadest above the middle, subcordate, cuspidate, pubescent on ribs and nerves of both surfaces, whitish or slightly rusty beneath, finely and sharply serrate and ciliate: fruiting catkins 7-10 in. long, remaining unopened on the tree till late summer or autumn, the caps. glabrous. E. Siberia, N. Japan.—Hardy and desirable, making a shapely head and bearing attractive foliage. It is sometimes confused with *P. suaveolens*. Wilson speaks of this tree as a magnificent poplar, the largest in eastern Asia, the trunk reaching 5 or 6 meters in girth.

24. *suaveolens*, Fisch. (*P. balsamifera* vars. *suaveolens* and *intermedia*, Loud.). A comparatively slow-growing tree of close, upright habit: young branches slightly pubescent above nodes: lvs. very thick and hard, finely serrate, oval to ovate and ovate-lanceolate in outline, and prominently whitened beneath, commonly rather small for this group, the margin ciliate, and finely crenate-serrate: twigs hard and cylindrical. Siberia, Mongolia, China.—It is considered to be a valuable tree for hot and dry interior climates; and it also has distinct merit for ornamental planting. It eventually becomes a large tree. The *Populus laurifolia* and *P. sibirica pyramidalis* of some American nurserymen are apparently variations of this type. *P. Przewalskii*, Maxim., is probably a form of this with glabrous branchlets and petioles. *P. szechuanica*, Schneid., a common tree in forests of Province Szechuan, W. China, growing to a large size: in habit and general appearance resembles *P. suaveolens* but the branches are more massive and the branchlets stouter: lvs. very large even on old trees, on suckers or very strong shoots usually ovate-elongated and the base either slightly or distinctly cor-

3144.
Populus Lindleyana above, with angled stem, and *P. fortissima* below. ($\times \frac{1}{2}$)

3145. *Populus Jackii*. An interesting poplar supposed to combine the features of the northeastern cottonwood and the balsam poplar. ($\times \frac{1}{2}$)

date or rounded and sharply glandular-crenate-dentate, on the old branches broad-ovate or ovate-orbicular with rounded or more or less cordate base and the margin more or less distinctly glandular-dentate. Growing at the Arnold Arboretum and the Rochester parks. *P. yunnanensis*, Dode, is allied to *P. szechuanica* but is insufficiently understood.

3146. Leaves of *Populus laurifolia* as illustrated in Ledebour's "Icones Plantarum." (Reduced.)

AA. Branchlets prevailing with projecting narrow ridges.

25. *laurifolia*, Ledeb. (*P. balsamifera* var. *laurifolia*, Wesm.). Fig. 3146. Tall tree with gray-brown bark and smooth angled twigs: lvs. ovate to ovate-oblong to ovate-lanceolate or even narrower, acuminate, sometimes undulate, rounded at base, finely toothed and somewhat ciliate, green above, more or less pubescent on midrib at maturity, whitish beneath: stamens 20–30; pistils sessile, 2-valved; staminate catkins about 3 in. long, pistillate 4–5 in. Siberia.

26. *Lindleyana*, Carr. (*P. laurifolia* var. *viminilis*, Dipp.). Fig. 3144. Lvs. mostly willow-like, long-elliptic, distinctly acuminate, or oval-elliptic on the older shoots, roundish at base, with pubescent petioles, fls. and fr. Perhaps a horticultural group, to which are probably to be referred the garden names *P. crispa* (with more or less crisped or crinkled margins), *P. Dudleyi* and *P. salicifolia*. As seen in cult. in this country (and very infrequent) it is a small or medium-sized tree, of slender growth and with a somewhat weeping habit when old. It is very like the native *Populus fortissima*, but is readily distinguished by its angled or furrowed sts., and less tapering and crisped lvs. which are conspicuously finely reticulated and whitened beneath. The color of its foliage is grayish green, and in this respect it affords a contrast to the native species. *P. fortissima* seems to be rather the better tree of the two, although *P. Lindleyana* has a more striking appearance. The botanical status of these trees is not clearly defined. By some, *P. Lindleyana* is referred to *P. laurifolia*, but the tree in cult. seems to be distinct.

27. *Simōnii*, Carr. (*P. laurifolia* var. *Simōnii*, Regel. *P. balsamifera* var. *Simōnii*, Wesm. *P. brevifolia*, Carr.). A strong strict tree, not large, with lvs. differing from those of *P. candicans* in having a rounded or tapering base and much finer teeth, but otherwise they are somewhat alike: shoots reddish brown and spotted, deeply grooved, somewhat drooping: lvs. small, mostly oval and tapering both ways, hanging on slender petioles. Amoor Valley to China, where it is common. G.W. 15, p. 246.—Intro. into France about 1861 by M. E. Simon, and somewhat planted in this country. It has been planted as far north as Man. with entire success. It is a very rapid grower, and is useful where quick-growing windbreaks are desired. There are fastigate and weeping forms. Shape of lvs. variable, those on vigorous shoots being round-obovate, acute-based, and mostly rounded at apex.

28. *trichocarpa*, Torr. & Gray. BLACK COTTONWOOD. Very large tree, to 200 ft. and trunk to 8 ft. diam., with wide head or top and upright branches: lvs.

varying from narrow- to broad-ovate, truncate or cordate at base, acute or taper-pointed at apex, finely serrate, to 8–10 in. long, shining green above and rusty but becoming whitish beneath: catkins 2–5 in. long; stamens 40–60; pistillate catkins loose-fld., in fr. becoming as much as 10 in. long; ovary 3-carpelled: caps. nearly sessile. Calif. to Brit. Col. and Alaska, reaching an elevation of 6,000 ft. S.S. 9:493. G.F. 5:281.—Aside from the conifers, it is said to be the largest tree in Ore. to Brit. Col. For *P. hastata*, see No. 17.

Following are supposed hybrids in the balsam poplar group:

(a) *P. berolinensis*, Dipp. (*P. certinensis*, Dieck. *P. pseudo-balsamifera*, Fisch.). Columnar tree supposed to be of hybrid origin, with short ascending branches, the growths densely pubescent and the young ones slightly winged but often becoming nearly or quite smooth at maturity: buds greenish, pointed, viscid: lvs. on strong shoots 3–4 in. long, ovate or ovate-rhombic, mostly rounded but sometimes cuneate at base, contracted into a long glandular acuminate point, glabrous on both surfaces, greenish or slightly whitish beneath, the margin not ciliate and with a very narrow translucent edge visible under a strong lens, the margins usually regularly crenate-serrate and sometimes with irregular shallow lobes. Perhaps a hybrid between Lombardy poplar and *P. laurifolia*. The name *P. certinensis* was applied to the staminate plant.

Whether the *P. certinensis* grown in N. Amer. (Fig. 3147) all belongs with *P. berolinensis* is very doubtful. Some of it seems to have many of the characters of *P. deltoides*. As grown in nurseries and collections here, it is a very rapid-growing and hardy tree, with a strong central leader and very heavy dense foliage; differs from *P. monilifera* as follows: lvs. broad-ovate in outline, with a rounded or tapering base and rather short point at the apex; the margin rather closely-toothed, wavy; lf.-stalk comparatively short, only moderately flattened, glandless at the top; stipules present and conspicuous: bud long; shoots slightly hairy.—The foliage on the old wood or upon slow-growing shoots is very unlike that upon the vigorous branches and is almost identical with that of the balsam poplar, being broadly oval, with finely serrate margins, and whitish beneath. The twigs, also, are cylindrical. But the strong shoots are strongly angled or grooved and the foliage is much like that of the native cottonwood, but darker; and the growth is more close and erect. The sketch in Fig. 3147 distinguishes the lvs. The *Certinensis* poplar is a more rugged tree than the cottonwood, with healthier foliage in the presence of li.-rust, and its wood is said to be valuable. It has been much planted in the N. W., and deserves to be widely distributed. Its effect in the landscape is considerably unlike that of the cottonwood. Its lvs. stand out more horizontally, while those of the cottonwood hang loosely and often vertically and therefore give the tree-top a heavier look. The terminal spray of the two is particularly distinguishable in this regard. The lvs. of *Certinensis* upon the strong, erect shoots stand almost at right angles to the shoot, and, at some distance, therefore, present only their ruffled edges to the eye, producing a unique and picturesque effect. The illustration (Fig. 3147) represents a top leaf of *P. certinensis* as grown in this country, but the name may not be correctly placed.

(b) *P. Wöbstii*, Schroed. (*P. Wöbsky*, Hort.?). Buds very viscid: lvs. 4–6 in. long and 2 in. broad, lanceolate, with widest part about the middle, narrow but rounded at base, gradually tapering toward the bluntly acuminate apex, slightly pubescent, white beneath, ciliate and crenate-serrate; petiole with few scattered hairs: branchlets glabrous.

(c) *P. Rasumowskyana*, Schroed. Buds pointed, viscid: lvs. on young trees and vigorous shoots 4 x 3 in., orbicular-ovate, rounded or subcordate at base, contracted above into a gland-tipped acuminate apex, very nearly glabrous, pale beneath, the margin glandular-crenate and not ciliate; petiole terete, grooved above; branchlets glabrous, ridged. *P. Nolestii*, as it has been grown in this country, is either this form or very like it, but is little understood.

(d) *P. Petrowskyana*, Schroed. Very like *P. Rasumowskyana*, but with minute pubescence on branchlets and petioles; lvs. on vigorous shoots 5 x 4 in., ovate, cordate, the apex long-acuminate, pale beneath; serrations deeper than in last.

VI. VARIABLE-LEAVED POPLARS. Lvs. remarkably polymorphous or diverse on the same plant, from very narrow to broad, coriaceous and reticulate, the petiole more or less cylindrical, the buds little if at all viscid: stamens few (about a dozen): caps. pedicellate, elongated; stigmas 3.

29. *euphratica*, Oliver (*P. diversifolia*, Schrenk. *P. ariana* and *P. Litwinowiana*, Dode). Medium-sized tree,

3147. *Populus certinensis* of American plantations. (X 1/4)

to 50 ft., attaining 2 ft. or more in diam., with pubescent not viscid buds and terete branches: lvs. on young shoots broad-linear (3-6 in. long) or oblong, short-stalked, entire; on short shoots or older parts half as long, ovate to rhombic to orbicular and more or less lobed or cut, at base rounded, cordate or cuneate, the stalk 1-2 in. long: catkins loose; stamens 8-12, scales cut, and disk orbicular; pistillate disk tubular and cleft: caps. to $\frac{1}{2}$ in. long. Egypt and Syria to Cent. Asia and China. Gt. 7, p. 170.—It is the "willow" of the Children of Israel; perhaps planted within our range. *P. pruinosa*, Schrenk, is a related tree of Turkestan and S. W. Siberia, with bark on the old trunks distinctly and deeply grooved as in ash and elm, whereas *P. euphratica* has a shaggy bark: lvs. ovate-elliptic to reniform, never lanceolate, entire. *P. Denhardtiorum*, Dode, a tree 60-80 ft. high in E. Trop. Afr., from sea-level to 1,500 ft. altitude, differs from *P. euphratica* in female racemes being shorter, perianth more deeply divided, ovary larger, and with a very large plane stigma: petioles twisted, so that the lvs. hang vertically. Tree used by the natives for dug-out canoes.

L. H. B.

PORÀNA (native name). *Convolvulaceæ*. Large twining annual herbs or shrubs, sometimes grown for ornament.

Leaves petioled, ovate, entire: infl. cymose or racemose; fls. purple, steel-blue or white; sepals in fl. small, narrow, in fr. all or 3 much enlarged; corolla campanulate or funnel-shaped, wide- or narrow-mouthed; limb 5-plaited, nearly entire or lobed; ovary 2-celled, 4-ovuled: fr. a globose membranous oblong or obconic caps. indehiscent or 2-valved.—About 15 species from Trop. E. Afr., oriental tropics and N. Austral.; 1 species reported from Mex. The two following species have been intro. into S. Calif., but are said to be hardly worth growing. *P. paniculata*, Roxbg. Strong shrubby climber often 30 ft. high: lvs. 5x3 in., pubescent above: panicles terminating every branchlet with innumerable fls.; sepals in fl. linear-oblong; corolla glabrous, campanulate, white, very short-lobed: caps. globose, hairy. India, Malaya. Gn. 61, p. 323. *P. racemosa*, Jacq. f. An annual, forming dense, not lofty masses: lvs. 2-3 x $1\frac{1}{2}$ in.: racemes lax; bracts at the forks leafy, sessile, scarious in fruit: sepals in fl. linear-oblong, puberulous; corolla lobed nearly half-way: caps. apiculate, glabrous. India. Called the "snow-creeper" by the English as the masses of white fls. resemble snow in the jungle.

F. TRACY HUBBARD.

PORANTHÈRA (Greek, referring to the anthers opening by 4 pores). *Euphorbiaceæ*. Plants rarely grown in greenhouses as ornamental subshrubs. Heathlike, herbaceous to somewhat woody: lvs. alternate or rarely opposite, small, narrow, margin recurved: fls. small, in dense, short-peduncled racemes or heads, monocious; calyx imbricate, petals present, at least in the staminate fls.; anthers 4-celled, opening by 4 pores; ovules 2 in each cell. Five species in Austral. There are no well-known related genera. *P. ericifolia*, Rudge. Six to 12 in. high: lvs. linear, crowded, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. white, in a dense terminal corymb. E. Austral. In cult. in Eu. Peat soil is suitable for its cult. It is prop. from seeds.

J. B. S. NORTON.

PORTENSCHLÀGIA (named for F. von Portenschlag-Ledermayer, an Austrian botanist, 1772-1822). *Umbelliferae*. Perennial herb, tall, much branched: lvs. ternately pinnatifid with filiform ultimate segms.: infl. a many-rayed composite umbel; fls. polygamous:

fr. ovate-cylindrical, in cross-section almost circular. One species from Dalmatia. There is also another *Portenschlagia* which belongs to the *Celastraceæ* and is included in *Elæodendron*. *P. ramosissima*, Vis. Tall and much branched: ultimate segms. of lvs. $\frac{1}{2}$ -1 in. long: fls. yellowish white; involucre bracts numerous, often membranous at the margins; petals hairy: fr. shortly hairy. Probably sparingly cult. abroad.

PORTLÀNDIA (named in honor of a duchess of Portland). *Rubiaceæ*. Glabrous shrubs and small trees, useful for the ornamental bloom.

Leaves opposite, thick-leathery, petiolate, oblong or linear-oblong; stipules between the petioles, connate with the petiole forming a sheath, deciduous: fls. large, 1-3-fld. on axillary peduncles; calyx 5-lobed, persistent;

3148. *Portlandia pterisperma*. ($\times \frac{1}{2}$)

corolla large, subcampanulate or funnelform, 5-lobed; stamens 5; ovary 2-celled: fr. an obovoid-oblong caps., turbinate or clavate, leathery.—About 10 species. Mex., W. Indies, but little known as horticultural subjects; probably useful far S.

platántha, Hook. Low shrub $1\frac{1}{2}$ -3 ft. high, glabrous: lvs. opposite, nearly sessile, elliptical-ovate, acute, evergreen, subcoriaceous; stipules broadly triangular, obtuse: calyx-lobes 4, spreading, leafy, lanceolate; corolla white, broadly funnelform approaching to campanulate, 5-lobed, the lobes spreading, ovate. Amer. B.M. 4534.—Requires moist tropical greenhouse heat and a mixture of loam and leaf-mold or peat-soil. Prop. by cuttings.

pterospérma, Wats. Fig. 3148. Shrub or small tree, 2-10 ft.: lvs. thin and deciduous: fls. numerous upon the young slender branches, 2 at nearly every node, pure white, funnelform, nearly 3 in. long; lobes of the corolla triangular, folded edge to edge in the bud so that it is strongly angled. Mex. G.F. 2:209 (adapted in Fig. 3148).—Probably hardy in the Gulf states and possibly in cult.

Other species which may appear in cult. are *P. coccinea*, Swartz, a Jamaican species with scarlet fls. and yellow anthers, and *P. grandiflora*, Linn., a native of the W. Indies with white fls., reddish inside at the throat and 5 in. long, growing 10-14 ft. high.

F. TRACY HUBBARD.

PORTULACA (Latin name, of uncertain history). *Portulacacææ*. PURSLANE. Low fleshy often trailing annual or perennial herbs, one of which is a common flower-garden plant, and one of which is sometimes grown in its horticultural form as a pot-herb.

3149. Capsules of *Portulaca grandiflora*. ($\times \frac{1}{2}$)

Leaves mostly alternate, thick, sometimes terete, entire; fls. mostly terminal, usually with 5 distinct petals and with several to many stamens, both borne on the calyx or receptacle-rim; fr. a small conical circumscissile caps. (Fig. 3149), containing many small seeds.—About 40 species in the tropical and temperate regions, mostly American. The fls. of *portulaca* open in direct sunshine, but close in shadow. Two annual species are in cult., both thriving in the hottest exposures.

grandiflora, Hook. ROSE MOSS. Fig. 3150. St. slender and terete, prostrate or ascending, not rising over 6–12 in., hairy in tufts at the joints; lvs. scattered or somewhat clustered, short and terete; fls. large (usually 1 in. or more across in the cult. forms), terminal and subtended by clustered lvs., in many bright colors, soon withering: seeds small, metallic-gray or gray-black. Brazil and S. B.M. 2885. R.H. 1877:90. Gn. 45, p. 436. G. 31:719.—Said to be perennial under glass. Runs into many garden forms, as: Var. *Thellusonii*, Hort. (*P. Thellusonii*, Lindl.), with handsome orange-scarlet fls. B.R. 26:31. R.H. 1852:5. Var. *splendens*, Hort. (*P. Gilliesii*, Hook.), light red-purple. B.M. 3064. Var. *albiflora*, Hort., clear white. Var. *sulphurea* or *Thórburnii*, Hort., dark yellow. Var. *caryophylloides*, Hort., red, striped white. Var. *Bédmannii*, Hort., clear white and purple-striped.—Colors

3150. *Portulaca grandiflora*. ($\times \frac{1}{2}$)

of the cult. *portulacas* range from pure white to yellow, rose, scarlet, deep red, and almost purple, with many striped forms. There are also many full double strains. The rose moss is most easy of cult. if it is given a hot and rather dry soil. It needs full sun. The seeds require a rather high temperature for germination, and therefore they are sown rather late,—near corn-planting time. Sometimes they are started indoors, but

usually they are sown directly where the plants are to stand. The soil need not be rich. The plant makes excellent edgings, and is good for growing in dry rock-work. A large patch of it gives a brilliant display of color in sunny weather, but the fls. do not open in dull weather. Seed of the double varieties produces more or less single-fl. plants, unless saved from cuttings of double-fl. plants, but the singles usually bloom earlier than the doubles. Let the plants stand 10–12 in. apart. They are tender to frost. The plant often self-sows, and in some places it persists about old gardens. *Portulaca grandiflora* was first described by Hooker in 1829 in the "Botanical Magazine." The fls. were described as "orange-colored, or of a very bright reddish purple."

The plant was "discovered by Dr. Gillies, growing in light sandy soil, in various situations between the Rio del Saladillo, or western boundary of the Pampas, and the foot of the mountains near Mendoza. On the western side of Rio Desaguadero plants were in great profusion, giving to the ground over which they were spread a rich purple hue, here and there marked with spots of an orange color, from the orange-colored variety which grew intermixed with the others."

oleracea, Linn. PURSLANE. PUSLEY. Fig. 3151. A common trailing weed in sandy ground, but also cult. in improved strains as a pot-herb: lvs. small, spatulate or narrow-obovate, very obtuse, thick, dull green or reddish; fls. small, yellow, the 7–12 stamens sensitive to a touch. Widely distributed in many countries; probably native to the southwestern parts of the U. S., but it is considered that it is intro. into the E. and N. In sandy and loamy soils it is one of the commonest and most persistent of weeds, but it is little known on heavy lands. The common wild plant is prized for "greens" in some regions, but the French upright forms are much better, as they are larger and more tender; these improved varieties look very different from the common "pusley;" they are easy of cult. For a discussion of the nativity of purslane in N. Amer., see Gray & Trumbull, Amer. Jour. Sci. 25, p. 253. L. H. B.

3151. Pusley.—*Portulaca oleracea*.

PORTULACARIA (similar to *Portulaca*). *Portulacacææ*. Glabrous shrubs or small trees: lvs. opposite, obovate, fleshy; fls. small, rose, fasciated in the upper axils, forming a leafy panicle; sepals 2, short; petals 4–5, longer; stamens 4–7, inserted at the base of the petals; ovary free, 3-cornered, 1-ovuled; caps. 3-winged, indehiscent. Two species, S. Afr. *P. afra*, Jacq. Small tree, 10–12 ft. high: branches opposite: lvs. obovate-roundish, 4–6 lines long; peduncles compressed and branched; pedicels ternate; fls. small, pink. S. Afr.

POSOQUERIA (from a native name in Guiana). *Rubiaceæ*. Glabrous shrubs or small trees with terete branches, for the warmhouse, of which only one has appeared in the American trade, although some other species are rather commonly cultivated abroad.

Leaves opposite, coriaceous, entire; stipules between the petioles, rather large, deciduous; fls. in terminal corymbs, fragrant, white, rose, or scarlet; calyx 5-toothed; corolla long-tubed, limb 5-lobed; stamens 5;

XCI. Harvest scene in the potato country.

ovary 1-2-celled; berry ovoid, rather large, fleshy.—About 15 species in Trop. Amer.

longiflora, Aubl. (sometimes erroneously written *P. longifolia*). A handsome free-flowering bush 5-8 ft. high: lvs. oblong, acuminate, narrowed at the base, thick and shining: fls. 12 or more in a cluster, 3-5 in. long, waxy white, very fragrant, the slender tube curved, hairy in the throat. French Guiana.—Prop. by cuttings of ripening wood.

densiflora, Hutchins. Evergreen few-branched shrub: lvs. ovate-elliptic, apex subacute or short-acuminate, base rounded or sometimes slightly cuneate: fls. in a congested corymb, short-peduncled; calyx deeply 5-lobed; corolla white, then yellow, the very long slender tube densely villous at mouth; stamens 5, at first connate then spreading. Brazil. G.C. III. 57:307.

macropus, Mart. Branches terete: lvs. long-petioled, linear- or ovate-lanceolate, acuminate, base acute or rounded: infl. many-flid., corymbose; fls. sessile or subsessile; calyx pilose outside; corolla-tube elongate, slender, with a papillose mouth; lobes of limb somewhat acute; ovary turbinate. Brazil. G.C. III. 57:313.

multiflora, Lem. Small tree: lvs. broad oval-oblong, base subcordate-rounded, apex abrupt acute-mucronate: infl. many-flid., in terminal subumbellate cymes; fls. long-tubed, white, erect, very fragrant and large; calyx small; corolla with 5 oblong lobes, the tips cuculate-rounded. Brazil. I.H. 16:597. G.L. 26:266.—This species has been recently referred to *P. macropus*.

F. TRACY HUBBARD.

POTAMOGETON (from Greek words signifying that these are *river plants*). *Naiadaceæ*. PONDWEED. Fig. 640, p. 548. A rather large genus (about 100 species) of aquatic plants in temperate and sometimes in tropical regions, a few of which are sometimes grown in aquaria and ponds. Nearly 40 species are native to N. Amer. They are weedy plants, attaching themselves to the bottom in ponds, lake margins and in shallow streams, and holding their small spikes of inconspicuous fls. above the water in midsummer. In many of the species there are two kinds of lvs., the narrow submerged ones and the broad floating ones. The small perfect fls. have 4 greenish perianth-segms., 4 stamens, and usually 4 sessile 1-ovuled ovaries: fr. a nutlet with a coiled or hooked embryo. The potamogetons are very difficult plants for the systematic botanist, and it is not worth while to describe any of the species here. There is none which is generally known in the trade. They are likely to be weeds in lily-ponds. For the American species, see Morong, Mem. Torr. Club 3, No. 2; also Pflanzenreich, hft. 31. Three species have come into slight notice in American gardens: *P. crispus*, Linn., and *P. natans*, Linn., natives, and *P. densus*, Linn., European. Easily grown. L. H. B.

POTATO. One of the most widely utilized and valuable of esculent tubers, produced underground as thickened stems. It is commonly known as the "Irish," "white," or "round" potato to distinguish it from the sweet potato; botanically it is *Solanum tuberosum*. See *Solanum*.

The potato is one of the most universally cultivated plants of the United States and Canada, and it is becoming increasingly important as an article of human food. It ranks sixth in agricultural importance in the United States. This country produces, however, only about one-fifth as much as Germany. This is due to the fact that the German consumption of potatoes per capita is about two and a half times as great as ours, and that more than 50 per cent of the German crop is used either for stock-food or for conversion into starch, alcohol, or other industrial by-products. Potatoes, at present, are used very little for these purposes in this country, less than 1 per cent being so used.

The potato is closely allied, botanically, to several powerful narcotics, such as tobacco, henbane, and belladonna, and also to tomato, eggplant, and capsicum. Potatoes contain a small amount of a somewhat poisonous substance. When exposed to the direct rays of the sun and "greened," the deleterious substance is so greatly increased that the water in which they are boiled is not infrequently used to destroy vermin on domestic animals. In any case, the water in which potatoes are cooked should not be used in the preparation of other foods.

The potato is a native of the elevated valleys of Chile, Peru, and Mexico, and a form of it is found in southern Colorado. It probably was carried to Spain from Peru early in the sixteenth century. It seems to have been introduced into Europe as early as 1565. Sir Walter Raleigh, in 1585, is said to have brought back the potato from the "new country." Recent investigations, however, seem to give the credit of introducing the potato into England to Sir Francis Drake, in 1586. As *Batatas virginiana*, it was figured and described by Gerarde in 1597. It is probable that these circumstances led erroneously to giving the credit of introducing the potato to Raleigh instead of to Sir John Hawkins. The wild varieties in their native habitat still bear a close resemblance to cultivated varieties except for the enlarged vine and abnormal development of the tubers in the latter. In the seventeenth century the potato was cultivated in gardens in several European countries. It was recommended by the Royal Society of London in 1663 for introduction into Ireland as a safeguard against famine. The cultivation of the potato as a field crop became somewhat common in Germany soon after 1772, at which time the grain-crops failed and potatoes were a welcome substitute for the bread-corn. It was near the middle of the eighteenth century before it acquired any real importance in Europe, outside of Ireland and a few restricted localities in other countries. As late as 1771 only a white and red variety were mentioned in one of the most important English works on gardening. The

3152. Underground parts of potato plant, showing the fibrous roots and the stems ending in tubers. The old seed-piece is seen near the bottom.

plants were enormously productive, but the tubers were poor in quality, so poor in fact that their chief use was as a food for domestic animals; and only when the bread-corns failed were they used to any extent, and even then only as a substitute. By 1840 the potato had been largely substituted in Ireland for the cereals and other similar food-crops, as the yield of potatoes in weight exceeded by twenty to thirty times the yield of wheat, barley, or oats on an equal area of land. This large dependence on a single food-crop finally resulted in a wide-spread famine. The potato blight which appeared in the United States in 1845 devastated Ireland in 1846. During two years, 1846 and 1847, a conservative estimate places the numbers who perished for want of food or from diseases caused by a meager

diet of unhealthy and unnutritious food at 600,000. By 1848 the plague had virtually disappeared.

The roots of the potato are distinct from the tubers. Usually, two to four roots start from the stalk at the base of each underground stem which, when enlarged at the end, forms the potato. (See Fig. 3152.) Roots may also start where underground stems are wanting. The potato is a perennial plant. The accumulated starch in the tubers furnishes an abundant supply of nourishment for the plants growing from the eyes or buds until they are well above the ground. So much food is stored that not infrequently small young tubers are formed on the outside of the potatoes left in the cellar during the summer. Potatoes grow from 2 to even 3 feet high, have smooth, herbaceous stems, irregularly pinnate leaves, and wheel-shaped flowers, varying in breadth from 1 to 1½ inches and in color from bluish white to

very low, good marketable tubers are not used for starch. The potato has many other uses which have been much less developed in the United States than in Europe, but there is a rapidly increasing tendency for their uses in the arts here. It is used in the textile industries, in the manufacture of woolen, linen, and silk goods; for the manufacture of potato flour, glucose, syrup, candy, desiccated potatoes for food, industrial alcohol, mucilage, dyes, stock-feed, and so forth.

The dry matter of potatoes is composed largely of starch. A high starchy content is desirable because it makes a mealy potato which is demanded in America. Being deficient in nitrogen, the potato is ill adapted for an exclusive diet and should be used in connection with food containing a high percentage of proteids, such as lean meat, peas, beans, and eggs. The lack of vegetable fats may be supplied by butter, gravy, or oatmeal. The composition of the potato varies widely. An average of 136 analyses is as follows:

	Water Per cent	Ash Per cent	Protein Per cent	Starch Per cent	Fat Per cent
Potatoes.....	78.	1.	2.2	18.	.1
Oatmeal.....	7.9	2.	14.7	67.4	7.1
Graham flour.....	13.1	1.8	11.7	69.8	1.7

The nutritive ratio of wheat is 1 to 5.37, almost perfect; that of potatoes 1 to 18.29, much too wide. Many foods in their natural state, as potatoes, are more or less deficient in mineral matter. Notable among these are rice and wheat flour—the former containing but 0.4 per cent and the latter 0.5 per cent of ash.

The main potato industry in the United States is confined to several potato-growing sections in widely separated parts of the United States. The most important of these are Aroostook County, Maine; the Norfolk and Eastern Shore trucking regions of Virginia and Maryland; the Red River Valley of Minnesota and North Dakota; the Kaw Valley of Kansas; the Greeley and Carbondale districts of Colorado; the Twin Falls country of Idaho, and the San Joaquin and Sacramento valleys of California. In these regions, the climate and soil are perfect for the best potato production.

Varieties.

There are many hundred varieties of potatoes. The older varieties run out in the course of time and are supplanted by new ones. The running out is largely due to the fact that growers, as a rule, do not practise seed-selection. The new varieties are ordinarily produced either from hybridized seed or from bud-sports. The latter are somewhat common. Red tubers are now and then found in white hills, and vice versa. Other differences are taken advantage of by breeders.

Of the many varieties listed in seedsmen's catalogues and found on the market, however, only a very few are of commercial importance. Fitch, of the Iowa State College, has made a thorough trial for a number of years of all varieties of commercial importance in the United States and Europe. He also made a canvass in person and by letter of the markets of the United States. The result was that only a few varieties were found to be of much market value. He lists the following varieties as being the most valuable in the United States in order of their importance: Rural New Yorker, Green Mountain, Early Ohio, Burbank, Irish Cobbler, Bliss Triumph, Peerless (Pearl). Many other varieties, of course, have local importance and perhaps outyield the standard varieties named above.

New varieties are being produced constantly, a very few of which may prove to be better than the standard sorts, but most of them are worthless.

William Stuart, of the United States Department of Agriculture, has recently made a very comprehensive and admirably arranged classification of potatoes, as follows:

3153. Potato, to show the difference in the progeny or yield of two tubers. One tuber cut into four pieces yielded the product from four hills shown in the left-hand column; another tuber similarly cut and planted, yielded the four hills shown in the right-hand column.

purple. They bear a globular purplish or yellowish fruit or seed-ball of the size of a gooseberry, containing many small seeds. As many as 297 seeds have been found in a single seed-ball.

The cultivated potato of today has undergone a remarkable change since its first introduction into Europe by the Spaniards. Some of this change has been brought about by better cultivation, but most of it is due to breeding. The tubers of the wild *S. tuberosum* were small and attracted little attention. Heriot, in his report on Virginia, describes the plant "with roots as large as a walnut and others much larger; they grow in damp soil, many hanging together as if tied on ropes." The modern potato has been bred so that the hills contain four to six tubers of uniform size, weighing, perhaps, two pounds. (See Fig. 3153.)

The uses of the potato are wide and varied, but taking the world over, its greatest value is as a food-crop. It is probably eaten by a greater proportion of the earth's inhabitants than any other crop except rice. It is extensively used for the manufacture of starch. The great potato-growing sections of the United States, especially Aroostook County, Maine, have many starch factories, where the tubers which are oversize or undersize or otherwise not fitted for ordinary food purposes are converted into starch. The price ordinarily paid for potatoes for starch-making is considerably less than that for eating, and unless the price for eating gets

Group 1.—Cobbler.

Tubers: Roundish; skin creamy white. Sprouts: Base, leaf-scales, and tips slightly or distinctly tinged with reddish violet or magenta. In many cases the color is absent. Flowers: Light rose-purple; under intense heat may be almost white.

Group 2.—Triumph.

Tubers: Roundish; skin creamy white, with more or less numerous splashes of red, or carmine, or solid red; maturing very early. Sprouts: Base, leaf-scales, and tips more or less deeply suffused with reddish violet. Flowers: Very light rose-purple.

Group 3.—Early Michigan.

Tubers: Oblong or elongate-flattened; skin white or creamy white, occasionally suffused with pink around bud-eye cluster in Early Albino Sprouts: Base light rose-purple; tips creamy or light rose-purple. Flowers: White.

Group 4.—Rose.

Tubers: Roundish oblong to elongate-flattened or spindle-shaped flattened; skin flesh-colored or pink, or (in the case of the White Rose) white. Sprouts: Base and internodes creamy white to deep rose-lilac; leaf-scales and tips cream to rose-lilac. Flowers: White in sections 1 and 2; rose-lilac in section 3.

Group 5.—Early Ohio.

Tubers: Round, oblong, or ovoid; skin flesh-colored or light pink, with numerous small, raised, russet dots. Sprouts: Base, leaf-scales, and tips more or less deeply suffused with carmine-lilac to violet-lilac or magenta. Flowers: White.

Group 6.—Hebron.

Tubers: Elongated, somewhat flattened, sometimes spindle-shaped; skin creamy white, more or less clouded with flesh-color or light pink. Sprouts: Base creamy white to lilac; leaf-scales and tips pure mauve to magenta, but color sometimes absent. Flowers: White.

Group 7.—Burbank.

Tubers: Long, cylindrical to somewhat flattened, inclined to be slightly spindle-shaped; skin white to light creamy white, smooth, and glistening, or deep russet in the case of section 2. Sprouts: Base creamy white or faintly tinged with magenta; leaf-scales and tips usually lightly tinged with magenta. Flowers: White.

Group 8.—Green Mountain.

Tubers: Moderately to distinctly oblong, usually broad, flattened; skin a dull creamy or light russet color, frequently having russet-brown splashes toward the seed end. Sprouts: Section 1—base, leaf-scales, and tips creamy white; section 2—base usually white, occasionally tinged with magenta; leaf-scales and tips tinged with lilac to magenta. Flowers: White.

Group 9.—Rural.

Tubers: Broadly round-flattened to short-oblong, or distinctly oblong-flattened; skin creamy white, or deep russet in the case of section 20. Sprouts: Base dull white; leaf-scales and tips violet-purple to pansy-violet. Flowers: Central portion of corolla deep violet, with the purple growing lighter toward the outer portion; five points of corolla white, or nearly so.

Group 10.—Pearl.

Tubers: Round-flattened to heart-shape-flattened, usually heavily shouldered; skin dull white, dull russet, or brownish white in section 1 or a deep bluish purple in section 2. Sprouts: Section 1—base, leaf-scales, and tips usually faintly tinged with lilac; section 2—base, leaf-scales, and tips vinous mauve. Flowers: White.

Group 11.—Peachblow.

Tubers: Round to round-flattened or round-oblong; skin creamy white, splashed with crimson or solid pink; eyes usually bright carmine. Includes some early-maturing varieties. Sprouts: Base, leaf-scales, and tips more or less suffused with reddish violet. Flowers: Purple.

Cultivation of potatoes.

The best soil for potatoes is a sandy loam, well drained but provided with an abundant supply of water. If the soil is deficient in moisture, the water from rainfall must be conserved by shallow cultivation. The ground should be plowed deeply and worked thoroughly so as to bring about perfect aëration. Whether the plowing should be done in the fall or the spring will depend largely upon the distribution of time and labor which the grower has at his disposal, except that hilly fields which are likely to wash during winter should not be plowed in the fall.

In cutting potatoes for planting, each eye should be supplied with an abundance of food to start the young plants vigorously. The pieces should be as large as possible and not bear more than two or three eyes. (See Fig. 3154.)

The potato is sensitive to frost, and therefore must complete its growth in most localities in three to six months. The period of development may be shortened by exposing the seed potatoes to the more or less direct rays of the sun in a temperature of about 60° for one or two weeks before planting. Some of the starch is

3154. A good cutting or seed-piece.

transformed into sugar, which causes the eyes or buds to develop into miniature short tough plants or "rosettes" which results, when the potatoes are planted, in hastening growth and shortening the period between planting and harvesting. Some varieties, when thus treated in warm rich sandy soil, produce merchantable tubers in six weeks.

The kind and amount of fertilizer which should be applied to potatoes will, of course, vary with conditions, such as method of rotation, natural fertility of the land, methods of growing the crop and so forth. The best method of rotation is one in which a crop of clover immediately precedes the potato-crop, particularly in the North. This furnishes nitrogen and leaves the ground in good mechanical condition. Ordinarily, potatoes require a fertilizer analyzing about 4 per cent of nitrogen, 7 per cent of phosphoric acid and 10 per cent of potash. If lime is applied to the land during the rotation, it should follow the potatoes and not precede them, as it furnishes the best conditions for the development of scab, which is a serious disease. The same is true of wood-ashes which, ordinarily, contain 30 per cent of lime.

Potatoes are planted either by hand or with a machine. Good-sized tubers should be cut into about four pieces and a single piece placed in each hill. The seed-pieces should be planted soon after cutting so as to prevent "bleeding" or loss of water from the cut surfaces. The depth of planting will depend upon circumstances, but ordinarily 4 to 6 inches may be considered an average depth. The planting-machines are usually drawn by two horses and perform several operations at once. They open the furrow, distribute the fertilizer, cover it slightly so that it will not come into direct contact with the seed, drop the seed-pieces and cover them. Sometimes a heavy wheel, to act as a roller, is attached to the rear of the machine to pack the soil over the hills. By means of these machines, large acreages may be planted in a short time.

Potato fields should be given frequent and thorough tillage to keep down the weeds and conserve soil moisture. These cultivations should be shallow to prevent injury to the roots. The soil is cultivated until the plants are large enough nearly to fill the rows and have begun to "set" tubers. Further tillage is likely to injure the plants and reduce the yield.

After the plants are mature, the tubers are dug either by hand or with an elevator digger drawn by two or more horses.

Yields.

The yield of potatoes to the acre in the United States is meager, the average yield for the ten-year period 1900-1909 being 91.4 bushels. Under favorable soil and climatic conditions, with rational methods of procedure, 200 to 400 bushels are not uncommon, and under superior conditions more than 1,000 bushels to the acre have been secured. By dividing the eyes and planting them in the greenhouse in the winter, and after a little time re-dividing them, continuing this until many plants were secured, one grower was enabled to raise 2,558 pounds of potatoes in the open from one pound of seed, being an increase of more than 2,500 fold. Two other growers secured, by similar methods, 2,349 pounds and 2,118 pounds. The low average yield is due, in part, to the ravages of the many enemies of the potato plant, which, uncontrolled, sometimes destroy the crop and usually seriously diminish the yield. In the United States, the potato is not so universally used or so productive as in Europe, though its use as a food is steadily increasing.

In common commercial culture, the yield as well as quality may be greatly enhanced by care in selecting seed. The progeny of two similar potatoes is shown in Fig. 3153, showing the inherited performance of the tubers.

The average annual production in the United States from 1881 to 1890 was 169,809,053 bushels, while the yield in 1913 was 331,525,000 bushels, which sold for an average farm price of 48.9 cents a bushel. New York stands first in potato-production, producing 53,215,000 bushels of the total yield. The crop of Europe aggregates more than the entire wheat-crop of the world. The production of the European countries for 1913 was:

3155. Potato blight. True or late blight on the left; early blight on the right.

France, 477,111,000; Austria, 424,457,000; Germany, 1,988,591,000; Russia, 1,274,439,000; the United Kingdom, 283,912,000 bushels. In 1912 the United States exported 76,382,000 bushels and imported 80,134,000 bushels.

Enemies.

The most common enemy to the potato plant, the Colorado potato-bug, is easily destroyed by applications in a powder or in a liquid of paris green or arsenate of lead to the vines when the bugs first appear. The fungus, *Phytophthora infestans*, causes the true blight (Fig. 3155), which results in potato-rot. The true blight may be kept in check by frequent and thorough sprayings with bordeaux mixture. It is always well to incorporate arsenicals with the mixture, that any remaining bugs may be destroyed. The bordeaux mixture is also useful in protecting in part the plants from the flea-beetle. Two or three applications are usually made during the summer. The early blight is more common than the true or late blight. It causes the shriveling and death of the foliage (Fig. 3155). It is usually the combined result of several causes, chief amongst which are fungi, flea-beetle, drought. Thorough good care and spraying with bordeaux mixture are the best treatments. A good potato field is shown in Fig. 3156 (adapted from "American Agriculturist"); and the picture also shows a good hand-praying rig.

A. W. GILBERT.

Potatoes as a market-garden or truck crop.

The chief difference between potatoes as a field crop and a market-garden or truck-farm crop is that in the former case they are grown in rotation with other long-season plants and consequently may occupy the ground for the entire growing season, while in the latter they occupy the ground only a few weeks and are usually preceded and followed by some early or late garden crop the same year. In the North the crop is usually grown in the spring and early summer, but in the South it may be grown either in the early spring or late fall. The spring crop is grown to supply the demand for new potatoes in the early markets while prices are high, but the fall

crop is mostly consumed locally either for table purposes or for seed for the next spring crop. In the trucking region of the upper South, the spring crop is planted in January, February, or March and harvested in May and June, and the fall crop in July or August and harvested in October or November.

The favorite Virginia rotation starts with potatoes planted in February and harvested in June. Cowpeas are sown immediately for a summer cover-crop; these are plowed under in August as a means of improving the soil, and spinach is planted in September. This crop is harvested in January or February and garden peas are planted in rows 5 or 6 feet apart. The peas are interplanted in late March with cucumbers. The peas are harvested in April and May, and the cucumbers in June and July. The ground is planted to kale in August, which is harvested in midwinter and potatoes planted again in February or March. A second two-year rotation starts with potatoes planted in February followed by cowpeas or an annual grass for forage. Winter cabbage is transplanted to the field in November or January. Corn is planted after the cabbage is harvested in May or June. Cowpeas are planted between the rows of corn at the last working. The corn-stalks remain standing in the field until late fall when the grain is harvested and they and the pea-vines are worked into the ground to supply organic matter.

Since earliness, productiveness, and reasonable resistance to disease are the main requisites for truck-farm potatoes, the varieties that meet the requirements are limited. In the South Atlantic and Gulf states, Bliss Triumph is the leading variety, while in the Carolinas and Virginia, Irish Cobbler is the favorite; but in the upper Mississippi Valley, Early Ohio undoubtedly is in the lead.

Seed grown in Maine, Michigan, Wisconsin, or other northern states will produce potatoes of marketable size five to ten days earlier than locally grown seed. Consequently truck-farmers who wish to cater to the early market depend upon the northern tier of states for their seed-supply; but those who wish to sell on the midseason market are now largely using locally grown seed. Plants from northern-grown seed suffer more severely from certain diseases than do those from local seed, hence the extreme earliness of the crop from the

3156. Spraying potatoes.

northern seed is, to a marked degree, compensated for by the healthier vines and larger yield from local seed.

The seed-stock to be used in producing the home or locally grown seed is obtained from the North in the winter or early spring, and held in cold storage until July or August, when it is planted. The tubers are harvested after the vines are killed by frost in October or November, and are placed in farm storage until needed for planting.

The land should be broken with a turn-plow a month or six weeks in advance of planting the potatoes, if the preceding crop in the rotation will admit. It is best to apply the stable-manure to some preceding crop in order that it may be well decayed before the tubers are planted. After the ground is thoroughly harrowed, the rows should be marked out about 3 feet apart. If drainage is not good it is well to open the furrow with a small turning-plow in order to expose a large surface to the action of the sun, air, and frost. A few days before planting, the furrows should be reopened, the fertilizer required distributed in them. It should be thoroughly mixed with the soil to prevent its coming into direct contact with the seed-tubers when they are planted.

In forcing potatoes, especially in the cooler season of the year, it is customary to use from 1,500 pounds to 2,000 pounds of fertilizer analyzing 5 to 6 per cent nitrogen, 6 to 7 per cent phosphoric acid, and 5 per cent potash, to the acre. The potatoes will not use all of this, but that remaining after they are harvested is available for subsequent crops. About one-third of the nitrogen in the fertilizer should be obtained from nitrate of soda and sulfate of ammonia and the other two-thirds from high-grade tankage, blood, and fish-scrap. By using nitrogen from the sources mentioned, the plants are enabled to obtain a constant supply throughout their growing-season. The phosphoric acid is obtained from acidulated South Carolina rock, and the potash, preferably, from sulfate of potash. Some growers apply about 1,000 pounds of the fertilizer in the rows before the tubers are planted and the balance as a side or top dressing when the plants are well started.

Whether the potatoes are to be planted by hand or a power planter, it is better to apply the fertilizer before planting, as much better distribution may thus be obtained. The larger number of truck-farmers follow the practice of hand planting, but the larger growers are now using horse-power machines. From three to five barrels of northern-grown seed and from two to three barrels of home-grown seed are usually required to plant an acre. The seed-pieces are placed 14 to 16 inches apart in the rows and are usually placed from 2 to 4 inches below the surface-level of the ground. The hand-planted tubers are covered by turning two furrows over them with a small turn-plow, thus forming a ridge 8 or 9 inches high above the tubers. If the discs of the power planter do not form such ridges, it is customary to add additional soil with the plow. These high ridges protect the seed-tubers against unfavorable weather conditions and enables them to develop strong roots before the sprouts appear above the ground, thus insuring rapid development when the season opens.

As soon as the tubers have formed sprouts an inch or two long, a light harrow is dragged diagonally across the ridges to kill any weeds that may be starting, and to provide a mulch over the row. A second dragging is given a week or ten days later, or just before the sprouts appear above the surface. The first working with the cultivator is given as soon as the plants have the row well outlined; subsequent cultivations are given at intervals of a week or ten days, a small quantity of soil being worked against the plants, thus forming low ridges at the later cultivations. If proper attention is given to the early cultivation, little or no hoe work need be expected.

The season for harvesting depends more upon market conditions than upon the maturity of the crop. If prices are high, digging may be started when the yield will not be over thirty or forty barrels to the acre, but if prices are moderate with indications for a steady demand, harvesting may be delayed for two or three weeks. In the meantime the yield will have increased from 25 to 50 per cent.

The crop is usually turned out of the ground with a plow while the vines are still green. The vines are then

pulled out of the ground with most of the tubers attached. These are carefully pulled from the roots, the others picked out of the loose soil and placed into piles on the ground. They are then graded by hand and packed in barrels for shipment. Great care is used in handling the new potatoes to prevent unnecessary bruising.

Mechanical diggers have not given satisfaction in the trucking region of the South, primarily because they bruise and break the skin, thus causing the tubers to present discolorations when placed on the market.

T. C. JOHNSON.

POTATO, AIR: *Dioscorea bulbifera*. **P. Onion:** *Onion*. **P., Sweet:** *Sweet Potato*, and *Ipomoea Batatas*.

POTENTILLA (diminutive of Latin *potens*, powerful; referring to the medicinal properties). *Rosaceæ*. CINQUEFOIL. FIVE-FINGER. A large group of perennial, rarely annual, herbs and shrubs found throughout the North Temperate and frigid zones; somewhat planted.

Leaves compound: appendages of the calyx 5, borne at the base of the 5 sepals, which in turn are borne upon the edge of a cup-shaped, dry receptacle; stamens 10-30, together with the 5 rounded petals inserted upon the margin of the receptacle (perigynous); pistils many, in fr. becoming minute achenes; style deciduous. Those in cultivation are all hardy perennial plants

3157. *Potentilla*, one of the hybrid garden forms known as *P. coccinea*; of the *P. atrosanguinea* group.

suitable for border planting. The most valuable double-fl. forms are hybrids. Monograph by T. Wolf, Bibliot. Bot. Heft 71:1908.

The American potentillas are generally rather unattractive plants with small flowers. They are, as a rule, very tenacious of life and do well with ordinary care. *P. fruticosa*, a handsome and distinct low shrub, prefers moist positions, but will grow in even very dry soil. When thoroughly established in moist soil, it is difficult to eradicate. *P. argentea* should be given a dry soil, preferably about rocks. It is tenacious of life and is rather attractive. *P. Hippiana*, a western species with comparatively large foliage of decided gray color, is hardy East. It is a good perennial, preferring dryish

soil. *P. tridentata* is an attractive evergreen species forming thick mats. It does well in any fairly rich soil in open or partially shaded positions. *Potentillas* are propagated by division or seed, the hybrids only by division. *P. fruticosa* may be increased by greenwood cuttings. (F. W. Barclay.)

Hybrid *potentillas* (Fig. 3157) have nearly all the good qualities in a border plant,—handsome foliage and free-blooming habit. They continue in bloom from spring until autumn, although most profusely in June and July. They cannot be said to be reliably hardy in the latitude of Boston, probably not above Washington. They do not grow over 2 feet and seldom need staking. A heavy soil suits them best. Choice varieties are propagated by division of the rootstock in spring; cuttings will not root. They run mostly in shades of maroon, scarlet, and orange, often beautifully banded with yellow. They bear seed freely, and when carefully hybridized one may get a very fine strain with a good proportion of double blooms. Seedlings bloom the second year. Some of the species make neat rock-plants, especially *P. tridentata*, *P. verna*, and *P. argentea*;—the last, though common, is valuable in places in which other plants will not grow. (T. D. Hatfield.)

ARTIFICIAL KEY TO THE SPECIES.

- A. *St.* distinctly shrubby, diffusely branched..... 1. *fruticosa*
- AA. *St.* herbaceous or merely suffruticose.
- B. Basal lvs. pinnate, 5-7-foliolate.
- C. Lvs. white-tomentose, at least beneath.
- D. Fls. cymose: lfts. whitened both sides..... 13. *Hippiana*
- DD. Fls. lateral, solitary at the nodes: lfts. usually green above.
- E. Carpels dorsally furrowed: peduncles and sts. pilose; tomentum lustrous..... 31. *Anserina*
- EE. Carpels dorsally rounded: peduncles and sts. glabrate; tomentum dull..... 32. *pacifica*
- CC. Lvs. green both sides.
- D. Fls. white, rose, or dark purple; infl. more or less lax, diffusely cymose; petals exceeding the sepals.
- E. Lfts. round-elliptic or rhombic-ovate: carpels glabrous, smooth or rugulose: infl. glandular..... 10. *rupestris*
- EE. Lfts. oblong or cuneate-oblong or oblong-lanceolate: infl. not glandular.
- F. Carpels densely pilose: petals large, obovate, showy. 2. *Salesoviana*
- FF. Carpels glabrous: petals minute, ovate-lanceolate. 3. *palustris*
- DD. Fls. creamy yellow; infl. congested; petals not longer than the sepals..... 11. *arguta*
- DDD. Fls. bright yellow.
- E. Lfts. minute, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, dissected: petals shorter than the sepals..... 33. *Gordonii*
- EE. Lfts. large, 1 in. long or more, dentate or incised..... 12. *glandulosa*
- BB. Basal lvs. palmately 5-7-foliolate.
- C. Fls. white: lvs. white-silky or glaucous beneath..... 9. *alba*
- CC. Fls. yellow.
- D. Lvs. white-woolly or white stellate-canescens, at least beneath.
- E. Cauler with abundant rooting stolons: sts. scarcely exceeding the basal lvs., pilose with long horizontal yellowish hairs: lvs. canescent..... 29. *cinerea*
- EE. Cauler without stolons: sts. much exceeding the lvs., without the above hairs.
- F. *St.* 16-28 in. high: fls. 7-9 lines broad..... 14. *gracilis*
- FF. *St.* 6-16 in. high: fls. 4-7 lines broad..... 21. *argentea*
- DD. Lvs. green beneath, or somewhat silky.
- E. Fls. lateral, solitary at each node..... 30. *canadensis*
- EE. Fls. terminal and solitary or cymose.
- F. Lfts. large, 2-5 in. long: plants large.
- G. Infl. glandular: lvs. rugose, coarsely serrate-dentate..... 22. *recta*
- GG. Infl. glandless: lvs. not rugose, laciniate-pinnatifid..... 23. *laciniosa*
- FF. Lfts. small, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long: plants low.
- G. Style conical: fls. 1 in. broad..... 25. *pyrenaica*
- GG. Style clavate: fls. 5-12 lines broad.
- H. Stipules of basal lvs. broadly ovate or ovate-lanceolate: stolons scarcely elongated, clothed with dead stipules..... 27. *alpestris*
- HH. Stipules of basal lvs. linear, elongated: stolons much elongated, rooting, not clothed with dead stipules..... 28. *verna*
- CCC. Fls. purple or rose.
- D. Lvs. and sts. velvety with yellowish hairs: lvs. almost tomentose beneath..... 17. *hæmatochrus*
- DD. Lvs. and sts. not yellowish hairy: lvs. green both sides.
- E. Lfts. 5: petals clear purple with dark veins and dark spot at base: infl. not glandular..... 15. *nepalensis*
- EE. Lfts. mostly 7: petals dark purple: infl. glandular..... 16. *Thurberi*
- BBB. Basal lvs. palmately, or rarely pinnately, 3-foliolate.
- C. Fls. rose, white, or creamy white.
- D. Lfts. glabrous, or slightly strigose beneath, 3-toothed: fls. white..... 4. *tridentata*
- DD. Lfts. white-silky on both sides, 3-toothed or entire: fls. rose, rarely white..... 8. *nitida*
- DDD. Lvs. tomentose at least beneath; teeth several.
- E. Petals white or cream, narrow, cochleate, and dorsally villous..... 7. *speciosa*
- EE. Petals purple or red, broadly obovate, glabrous..... 19. *atrosanguinea*
- CC. Fls. yellow.
- D. Lvs. white-tomentose beneath, white-silky above (see also *P. grandiflora*).
- E. Margin of lfts. incised-serrate: fls. 1-1 $\frac{1}{4}$ in. broad..... 18. *argyrophylla*
- EE. Margin of lfts. crenate-serrate: fls. $\frac{3}{4}$ -1 in. broad..... 20. *villosa*

DD. *Lvs. not tomentose beneath.*

E. *Lfts. 3-toothed at apex*..... 5. *ambigua*

EE. *Lfts. several-toothed.*

F. *The lfts. small, ½ in. long or less: fls. 3-6 lines broad*..... 26. *dubia*

FF. *The lfts. larger: fls. ¾ in. broad or more.*

G. *Achenes pilose*..... 6. *eriocarpa*

GG. *Achenes glabrous, either smooth or rugose*..... 24. *grandiflora*

Section I. TRICHOCARPÆ. *Carpels completely or in part pilose (except P. palustris): receptacle long- and dense-pilose.*

Subsection A. RHOPALOSTYLÆ. *Style clavate.*

1. *fruticosa*, Linn. St. shrubby, much branched, mostly 1-4 ft. high, with peculiar shreddy bark: lvs. all cauline, pinnate; lfts. 3-7, small, 6-12 lines long, oblong-linear, acute, silky, with revolute margins: fls. numerous, bright yellow, showy, 8-16 lines broad; receptacle, carpels, and disk all long-hairy; style sub-basal, clavate. June-Aug. Boggy or dry, more or less calcareous soil, Eu., Asia, N. N. Amer. J.H. III. 31:602. —A useful shrub, flowering throughout the summer. Var. *Vilmoriniana*, Bean, has lvs. silvery white beneath and fls. creamy white. Var. *albicans*, Rehd. & Wilson, is similar but has yellow fls. China, and cult. Var. *dahurica*, Lehm., is white-fl. L.B.C. 10:914 (as *P. glabra*). Var. *Veitchii*, Bean, white-fl., is *P. fruticosa* × *P. dahurica* (*P. Friedrichsenii*, Spaeth). B.M. 8637. In nature, *P. fruticosa* runs into many forms.

Subsection B. NEMATOSTYLÆ. *Style filiform.*

Series A. SUFFRUTICOSÆ. *Suffruticose: fl.-bearing sts. terminal on the determinate plant axis.*

2. *Salesoviana*, Steph. Sts. 12-24 in. high, woody at base, laxly cymose above, and silky villous: stipules broadly scarious, fuscous: basal lvs. pinnate; lfts. 7-9, rarely 5, lower much smaller, all short-petiolulate, oblong or cuneate-oblong, coarsely and sharply serrate, thick or subcoriaceous, green and glabrous above, pale appressed pilose below, often furfuraceous and canescent: fls. 1¼ in. broad; sepals purple outside, yellowish within, twice as long as the appendages; petals broadly obovate, entire, about equaling the sepals, lilac or white suffused with rose; carpels villous; style lateral, filiform. June-Aug. Asia. B.M. 7258. —A beautiful and striking plant of dry stony places.

3. *palustris*, Scop. (*Comarum palustre*, Linn.). Suffruticose: stolons long, creeping and branched: aerial sts. ascending, 8 in. to 2 ft. long, glabrous, laxly cymose above and more or less pilose or glandular: basal lvs. pinnate, long-petioled; lfts. 2-3 pairs, contiguous, thick, not veiny, sessile, oblong-lanceolate, 1-3 in. long, evenly and sharply serrate, green above, glaucous beneath, often puberulent, rarely silky: fls. few; sepals dark purplish, large; petals small, ovate-lanceolate, acuminate, pale purple, often villous or ciliate, shorter than the sepals; receptacle spongy; carpels glabrous; style lateral, filiform. June-Aug. Very wet marshes, Arctic and Temp. Eu., Asia, and N. Amer. —A striking species for aquatic gardens. See *Comarum*.

4. *tridentata*, Soland. Caudex somewhat woody: sts. 1-12 in. high, slender: branches erect-spreading, appressed pubescent: lvs. mostly basal, long-petioled, ternate; lfts. ½-2 in. long, oblanceolate, truncate and 2-3-toothed at apex, cuneate and entire below, coriaceous, dark green, glabrous or strigose and paler beneath: fls. several, small, 3-5 lines broad, in a terminal, nearly naked cyme; petals oval, entire, exceeding the calyx, white; carpels villous; style sub-basal, long-filiform. June-Aug. Rocky places, N. E. N. Amer. —Good for dry banks and rockeries.

5. *ambigua*, Camb. Sts. slender, subrepent or ascending, tufted and branched, woody below: lvs. ter-

nate; lfts. subcoriaceous, lateral sessile, terminal long-stalked, obovate or orbicular-cuneate, nearly as broad as long, coarsely and obtusely 3-toothed, green above, glaucous beneath, appressed pilose on both sides or subglabrous: fls. solitary on the branches, long-peduncled, ¾-1 in. broad; peduncles strigose; appendages and sepals subequal; petals suborbicular, slightly retuse, much exceeding the sepals, yellow: carpels pilose. July, Aug. Himalayas.

6. *eriocarpa*, Wall. Caudex branched, woody: fl.-sts. flaccid, simple, ascending, 4-8 in. long, almost leafless, sparsely pilose or subglabrate, 1-2-fl.: basal lvs. ternate or pinnately 3-foliolate; lfts. more or less long-stalked, obovate-rhomboid, coarsely and sharply 5-7-toothed above, green both sides, subglabrous: fls. conspicuous, 1½ in. broad, long-peduncled; appendages broad, usually longer than the sepals; petals round-ovate, much exceeding the sepals, soft yellow with large orange blotch; carpels long-pilose; style subterminal, filiform or slightly swollen at the middle or above. July, Aug. Himalayas. —Showy for borders and rockeries.

Series B. HERBACEÆ. *Herbaceous: fl.-bearing sts. lateral on the indeterminate plant axis.*

7. *speciosa*, Willd. Caudex thick, branched, woody: fl.-sts. ascending, 2-10 in. long, few-lvd.: basal lvs. ternate, long-petioled; lfts. thick, obovate, terminal slightly stalked, all crenate-dentate above base, with short teeth, white-tomentose on both sides or only below: fls. 3-8, short-pedicelled, 7-9 lines broad; appendages narrow; sepals rather obtuse; petals scarcely exceeding the sepals, long-canaliculate-unguiculate, terminating in a very small ovate-cochleate limb, tardily deciduous, white or yellowish white, dorsally ciliate or more or less villous; carpels pilose; style subterminal, slender, not dilated. June-Aug. S. Eu.

8. *nitida*, Linn. Cespitose; caudex subligneous: fl.-sts. ascending, short, 1-2 in. long, usually not exceeding the lvs., apex 1-2-fl.: peduncles often glandular: basal lvs. ternate (rarely 4-5-nate), short-petioled, crowded; lfts. thick, sessile, oblong-obovate or subcuneate, apex with 3 incurved teeth, rarely entire, densely white-silky on both faces: fls. conspicuous, 9-12 lines broad or more; appendages narrow, shorter than the purple sepals; petals very short-clawed, broadly obovate, emarginate, twice as long as the sepals, rose or lilac, rarely white; filaments and anthers purple; carpels pilose; style subterminal, long, slender, purple. July, Aug. Mountains of S. Eu. —“One of the most beautiful of alpine fls.”

9. *alba*, Linn. Caudex thick, branched: fls.-sts. short, not exceeding the basal lvs., weak, decumbent, laxly 2-5-fl., sericeo-villous: basal lvs. long-petioled, 5-foliolate, some often ternate or 7-foliolate; lfts. sessile or short-stalked, all symmetrical but the outer shorter, oblong-lanceolate, apex acute and serrate, teeth few, appressed, terminal smaller, green and glabrous above, more or less densely white-silky, becoming glabrous and glaucous beneath: fls. long-peduncled, showy, 9-12 lines broad; appendages very narrow, shorter than the sepals; petals broadly orbiculate, somewhat longer than the sepals, white; carpels pilose; style subterminal, slender. April-June, and often Aug.-Oct. Cent. Eu. G. 37:98.

Section II. GYMNOCARPÆ. *Carpels glabrous: receptacle short-pilose to almost glabrous.*

Subsection A. CLOSTEROSTYLÆ. *Style subbasal, fusiform.*

10. *rupëstris*, Linn. Caudex thick, subligneous: sts. erect, 20 in. high or more, few-lvd., dichotomously branched and laxly corymbose above, glandular-hairy and hirsute: basal lvs. long-petioled, pinnate; lfts. 2-4 pairs, decreasing downward, distant, round-elliptic or rhombic-ovate, lateral sessile, terminal sessile or

stalked, margin irregularly biserrate, pilose and green on both faces, often glandular: fls. $\frac{1}{2}$ –1 in. broad, long-pedicelled; appendages much shorter and narrower than the sepals, often bi- or trifid; petals obovate, entire, equaling or much exceeding the sepals, white; carpels smooth or rugulose; style subbasal, glandular-thickened in the middle. May–July. Eu., Asia, and mountains of W. N. Amer.—Grows well in dry soil.

11. *argüta*, Pursh. Similar to *P. rupestris*, but with a more strict habit, more glandular-hirsute pubescence, more congested infl., and smaller cream-colored petals which scarcely exceed or are shorter than the sepals; calyx enlarging more in fr., and receptacle becoming elongated, much swollen and almost fleshy. June–Aug. N. Amer.—Good for dry rocky soil.

12. *glandulösa*, Lindl. Similar to *P. rupestris* and *P. arguta*: differs from the former in its golden yellow or pale yellow fls., and from the latter both in the color of the fls., and in the dichotomous and laxly cymose infl. June–Aug. W. N. Amer.—Grows well in dry sterile ground.

Subsection B. CONOSTYLÆ. *Style subterminal, conical.*

Series A. ERIOTRICHÆ. *Plant with some true tomentum.*

13. *Hippiäna*, Lehm. St. erect, 1–2 ft. high, silky, laxly cymose above: basal lvs. rather large, pinnate; lfts. 3–5 pairs, whitish-silky above, white-tomentose beneath, uppermost somewhat confluent, the others decreasing regularly toward base of lf., obovate-cuneate, 1–2½ in. long, obtusely incised-toothed: fls. $\frac{1}{2}$ –1 in. broad; appendages nearly equaling the calyx, acute; petals obovate, retuse, slightly exceeding the sepals, bright yellow; carpels glabrous, rugose; style papillose-thickened at base, tapering above to the enlarged stigma. June, July. W. N. Amer.

14. *grácilis*, Douglas. Erect and rather tall, about 2 ft. high, more or less white-hairy, erect-branched and cymose-paniculate above: basal lvs. long-petioled, digitate; lfts. 5–7, obovate or oblanceolate, 1–2 in. long, deeply and regularly incised-dentate, sparsely pilose or glabrous and green above, white-tomentose beneath: fls. 6–9 lines broad, showy; petals obcordate, exceeding the acuminate sepals, yellow; carpels glabrous and smooth; style subterminal, slender, thickened at the base. June–Aug. W. N. Amer.

15. *nepalénsis*, Hook. (*P. formösa*, Don. *P. Tónguei*, Hort.). St. stout, erect or ascending, 1–2 ft. high, purple: the branches laxly paniculate or raceme-like, hirsute, not glandular: radical lvs. long-petioled, palmately 5-foliolate, often 12 in. long; lfts. oblong-obovate, 2–3 in. long, veiny and rugose, crenate-serrate except toward the base, with broad and short sub-acute teeth, green both sides, sparsely appressed-pilose: fls. long-pedicelled, showy, 9–12 lines broad; calyx purple within; petals broadly obcordate, deeply emarginate, nearly twice the length of the sepals, clear purple with darker veins and dark-purple base; carpels glabrous, rugulose; style subterminal, thickened at the base, tapering above. July, Aug. Himalayas.—The branches elongate zigzag-like during the summer. A fine species.

16. *Thürberi*, Gray. Similar to *P. nepalénsis*, but finely glandular-hairy all over: lvs. mostly 7-foliolate; petals dark purple and scarcely exceeding the sepals: infl. more cymose. June–Aug. New Mex. and S. Calif.—Good for border planting.

17. *hæmatóchrus*, Lehm. St. stout, ascending, 8–16 in. high, densely cymose above, pubescent or canescent with yellowish hairs: basal lvs. with long and stout petioles, palmately 7-, rarely 5-foliolate; lfts. oblong-obovate, obtuse, thick, elevated-veiny beneath, crenate-serrate with small teeth, velvety above with yellowish subappressed hairs, more or less densely

white-tomentose below: fls. on thick pedicels, 9–10 lines broad; sepals purple within; petals broadly obcordate, longer than the sepals, dark purple; carpels glabrous, smooth; style subterminal, red, much thickened at the base. June–Aug. Mountains of Mex.—The yellowish pubescence is characteristic.

18. *argyrophýlla*, Wall. (*P. insignis*, Royle). Sts. erect, 8–16 in. high, nearly simple, leafy, cymosely few-fl., above puberulent and whitish tomentose: basal lvs. large, long-petioled, mostly ternate; lfts. subsessile, broadly obovate or elliptic-ovate or obovate-oblong, more or less rugose beneath, coarsely incised-serrate with acute teeth, more or less densely silky above, rarely subglabrate, densely white-tomentose beneath: fls. long-pedicelled, showy, 1–1¼ in. broad; petals broadly obcordate, twice the length of the sepals, yellow; carpels glabrous, smooth; style subterminal, greatly thickened at the base. June–Aug. Himalayas.—This species and the next are two of the most common species in cult., and are extensively hybridized with each other and with *P. nepalénsis*, giving rise to most of the hybrid potentillas of the trade. (Fig. 3157.)

19. *atrosanguínea*, Wall. Similar to *P. argyrophýlla*, but larger, more branched, lvs. less heavily silky-glossy and less white-tomentose beneath, usually more bluntly toothed: petals, stamens, and styles dark purple. June–Aug. Himalayas.—Parent of many garden forms.

20. *villösa*, Pall. Sts. stout, ascending, 4–12 in. high, few-fl., cymosely few-fl., densely silky-villous: basal lvs. long-petioled, ternate; lfts. sessile or nearly so, thick and veiny, suborbicular-cuneate, 9–15 lines long, lateral oblique at the base, all coarsely crenate-serrate with short teeth, margin somewhat revolute, densely silky-pilose above, densely white-tomentose beneath: fls. 9–12 lines broad, showy; sepals and bracteoles equal; petals broadly obcordate, 2–3 times the length of the sepals, golden yellow; carpels glabrous, smooth or rugulose; style subterminal, conical, moderately thickened at the base. June, July. Arctic Asia and N. W. Amer.—Showy, with beautiful lf.-rosettes.

21. *argétea*, Linn. Sts. several, ascending, rarely prostrate, slender, 4–20 in. long, laxly paniculate or corymbose above, white-tomentose: basal lvs. long-petioled, palmately 5- rarely 7-foliolate; lfts. broadly cuneate-obovate, 4–14 lines long, coarsely and regularly incised-dentate with 2–5 pairs of teeth, margins revolute, from green and glabrous to densely silky or tomentose above, densely white-tomentose beneath, very rarely tomentose and green beneath: fls. long-pedicelled, 5–7 lines broad; petals obovate, emarginate, scarcely exceeding the sepals, sulfur-yellow; carpels glabrous, rugulose; style subterminal, conical, papillose-thickened at the base. June–Aug. or Oct. Eu. and Asia, intro. in N. Amer.—Good for dry, sterile soil. Var. *calàbra*, Sir. (*P. calàbra*, Ten.). Lfts. dilated-fan-shaped, incised on outer edge, whitened on both sides: plant low: sts. stout, declined, condensed-cymose: fls. relatively large. Italy.

Series B. ORTHOTRICHÆ. *Plant with no true tomentum; pilose and often glandular.*

22. *récta*, Linn. Sts. stout, erect, strict, 12–28 in. high, leafy, dichotomously much branched and widely corymbose above, hirsute or pilose and pubescent, and more or less glandular: basal lvs. large, long-petioled, palmately 5–7-foliolate; lfts. 2–4 in. or more long, the outer smaller, all usually sessile, oblong, linear-oblong or oblong-obovate, regularly and coarsely serrate-dentate, green both sides, villous and rugose, thin: fls. 8–12 lines broad; petals obcordate, deeply emarginate, equaling or somewhat exceeding the sepals, yellow to golden yellow; carpels glabrous, very rugose; style swollen at the base. June, July. Eu.—Very handsome and showy. Var. *sulphúrea*, Lam. Petals sulfur-yellow, much exceeding the sepals: sts. and lvs. lighter

green. Widespread in Eu. Intro. as a weed in E. N. Amer.

23. *laciniōsa*, Waldst. & Kit. (*P. laciniata*, Amer. Hort.). St. stout, erect, forming clumps. 12–20 in. high, mostly reddish, laxly corymbose above, long-pilose with soft spreading hairs: basal lvs. palmately 7-foliate, rarely 5-foliate; lfts. green and pilose on both surfaces, not rugose, the terminal folded, all oblanceolate-oblong, 2–3 in. long, lacinate-pinnatifid, with 6–12 pairs of lanceolate or linear and incised teeth: fls. and general habit as in *P. recta*, to which it is closely related. S. Eu.

24. *grandiflōra*, Linn. Sts. ascending or erect, from a thick caudex, 4–15 in. high, the erect branches of the cyme few-flid., densely villous above, eglandular: basal lvs. long-petioled, mostly ternate; lfts. 7–15 lines long, lateral obliquely obovate, terminal cuneate-obovate, all incised-serrate toward the apex with 6–10 ovate or oblong acutish teeth, pubescent above, densely short-villous beneath, veiny, rarely whitened: fls. conspicuous, 9–15 lines broad; petals broadly obovate, emarginate, much exceeding the sepals, golden yellow; carpels glabrous, smooth or obsoletely rugose; style papillose-thickened at the base. July, Aug. Alps.—A good border plant.

25. *pyrenāica*, Ram. St. stout, arcuate-ascending from a thick subcespitose caudex, 4–10 in. long, racemously few-flid. above, pilose or somewhat canescent: basal lvs. both short- and long-petioled, palmately 5-foliate; lfts. small, sessile, cuneate-obovate or cuneate-oblong-obovate, 4–9 lines long, the outer smaller, all entire below, dentate toward apex with 5–7 pairs of short acutish or obtuse teeth, green and subglabrous above, densely pilose and subsericeous beneath: fls. 1 in. broad; petals large, broadly obovate, emarginate, much longer than the sepals, golden yellow; carpels glabrous, striate-rugulose; style thickened below. July, Aug. Pyrenees.—Closely related to *P. grandiflora*.

Subsection C. GOMPHOSTYLÆ. *Style subterminal, rarely lateral, clavate: plant with no true tomentum.*

26. *dūbia*, Zimm. Cespitose, forming mats, runners wanting: sts. slender, prostrate or ascending, $\frac{3}{4}$ –2 in. long, scarcely as long as the lvs., 1-flid., rarely 2–3-flid., pilose, eglandular: basal lvs. short-petioled, ternate; lfts. small, 4–5 lines long, broadly obovate, the outer strongly oblique, the terminal slightly petioled, all with 2–3 pairs of ovate, acute, or obtuse teeth, light green and glabrous above, strigose on the veins beneath: fls. small, 3–6 lines broad; appendages broad, obtuse or rounded; petals broadly obovate, slightly emarginate, exceeding the sepals, yellow; carpels glabrous, smooth or rugulose; style somewhat thickened below. July, Aug. Mountains of Eu. G. 36:483.—The smallest of European potentillas.

27. *alpēstris*, Hall. f. Caudex densely clothed with stipules; runners almost wanting: sts. slender, arcuate-ascending, rarely strict, few-lyd., 2–8 in. long, somewhat exceeding the basal lvs., laxly dichotomous-ramose at top, pilose above, rarely glandular: basal lvs. short-petioled, appendages 5-foliate, rarely 3- or 7-foliate; lfts. mostly sessile, obovate, crenate-dentate or deeply incised-serrate with 2–5 pairs of obtuse teeth, strigose or glabrous above, pilose or villous on the veins beneath, green both sides: fls. long-pedicelled, $\frac{1}{2}$ –1 in. broad; petals broadly obovate, emarginate, more or less exceeding the sepals, golden yellow, rarely paler, often with an orange spot at the base; carpels glabrous, rugulose or smoothish; style subterminal, clavate. June–Sept. Arctic and Alpine Amer., Eu., and Asia.—A close relative of *P. verna* but not forming such extended mats. Extremely variable.

28. *véna*, Linn. Caudex emitting runners, forming a thick turf: numerous, decumbent or ascending,

2–6 (rarely 12) in. long, dichotomously branched and laxly corymbose, pilose, rarely glandular, usually reddish: basal lvs. long-petioled, palmately 5-foliate, rarely 7-foliate; lfts. sessile or nearly so, cuneate-obovate, $\frac{1}{2}$ – $\frac{3}{4}$ in. long, toward the apex crenate-dentate to deeply incised-serrate, sparsely pilose and green above, green and pilose beneath: fls. long-slender-pedicelled; appendages oblong, obtuse; petals obovate to broadly obovate, emarginate, longer than the sepals, golden yellow, rarely paler; carpels glabrous, rugose; style subterminal, clavate. March–May, often also Aug., Sept. Eu.—Very variable. Dry or stony soil. For banks and rockeries.

29. *cinērea*, Chaix. Forming mats: sts. slender, ascending, 2–4 in. high, scarcely exceeding the basal lvs., few-flid.; basal lvs. palmately 5-foliate, rarely 3–4-foliate; lfts. narrowly cuneate-oblong-obovate or nearly oblong, rounded at apex, short-crenate-dentate, thick, rugose, sparingly stellate-tomentose above, densely so beneath, long-hirsute on both faces; appendages dilated and often bifid, scarcely shorter than the ovate, obtuse sepals; petals oblong-obovate, pale yellow, much exceeding the sepals; carpels glabrous, rugose; style subterminal, clavate. April–June. Alps.

3158. *Potentilla Anserina*, showing a plant in early summer before the runners start. Later the flowers are borne on the runners.

30. *canadēnsis*, Linn. Sts. slender, at first ascending, later prostrate and creeping, simple, flagelliform, 12–24 in. or more long, leafy, bearing solitary long-peduncled fls. at the nodes, villous, eglandular: basal and cauline lvs. slender-petioled, palmately 5-foliate; lfts. cuneate-obovate or oblong, coarsely dentate-serrate except at the base, green both sides, pubescent or glabrate above, more or less strigose-pilose beneath: fls. 5–6 lines broad; appendages narrowly lanceolate; petals broadly obovate, slightly emarginate, yellow, longer than the sepals; carpels glabrous; style subterminal, from clavate to fusiform. May–Aug. E. N. Amer. Mn. 3:38.—Good for dry, sterile, open soil.

Subsection D. LEPTOSTYLÆ. *Style lateral, short-filiform, of equal diam. throughout: plant with or without tomentum.*

31. *Anserina*, Linn. SILVER-WEED. Fig. 3158. Caudex thick; sts. simple, slender, prostrate and creeping, rooting at the nodes, often $2\frac{1}{2}$ or 3 ft. long, bearing solitary, long-peduncled fls. at the nodes, pilose-sericeous with ascending or somewhat spreading hairs: basal lvs. numerous, large, pinnate, mostly short-pedicelled; lfts. many pairs, decreasing in size downward, with minute ones interspersed, linear-oblong to oblong-ovate, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long, sharply serrate, green or whitened above, densely white to lustrous silky-tomentose beneath, very rarely green both sides: fls. large, 8–10 lines broad;

appendages usually lobed; petals obovate, entire, exceeding the sepals, golden yellow; carpels at maturity glabrous, thick, ovoid, corky, dorsally furrowed; style lateral, filiform. May-Aug. Gravelly, more or less calcareous shores. Most widespread of all potentillas, through the cold and temperate portions of all countries except possibly Afr.—Very decorative.

32. *pacifica*, Howell. Similar to *P. Anserina*; but sts., peduncles, petioles, and rachis glabrous or early glabrate: lfts. dull-tomentose beneath: achenes laterally compressed, firmer, rounded on the back, not furrowed. Along the coast of temperate and arctic E. and W. Amer., and E. Asia.—This species may be in the trade as *P. Anserina*.

33. *Gordonii*, Baill. (*Ivesia Gordonii*, Torr. & Gray. *Horkelia Gordonii*, Hook.). Caudex stout, woody, and cespitose: sts. erect, 4-12 in. high, and, like the lvs., glandular-pubescent or glabrous: lvs. pinnate, mostly basal, numerous; lfts. 10-20, divided into 3-5 oblong or linear segms.; cauline lvs. few, very small; fls. small and inconspicuous, in a crowded cyme; petals yellow, spatulate, shorter than the sepals; stamens 5-20, inserted on the edge of the cup-shaped receptacle at a distance from the carpels; style filiform, basal. Subalpine W. U.S.—Forms dense mats in dry soil. This species belongs properly to *Horkelia* (a genus apparently not known to the gardeners) and is generically distinct from *Potentilla* because of the more deeply cup-shaped receptacle. It is, however, known in the trade as a *potentilla*.

Following are some of the hybrid potentillas, the exact botanical status of which has not been worked out and which have not been standardized as to nomenclature: *P. bicolor* (*P. argyrophylla* × *P. atrosanguinea*, according to Wolf), orange and vermilion.—*P. cardinalis* (*P. atrosanguinea* × *P. nepalensis*, according to Wolf), brilliant cardinal.—*Dr. André*, golden yellow suffused with vermilion.—*Eldorado*, purple suffused with yellow.—*Emile*, bright bronzy red.—*Gloire de Nancy*, golden yellow.—*Hamlet*, dark carmine.—*P. Hopwoodiana* (*P. nepalensis* × *P. recta*, according to Wolf). Lfts. 5-6; petals at base deep rose, at center pale rose, margins whitish.—*P. hybrida*, name applied to various hybrids. R.H. 1890, p. 305. Gn. 16:462; 25:514.—*Jeanie Salter*, orange, shaded scarlet.—*Le Vesuve*, floriferous, light red margined with yellow or scarlet.—*P. Mac Nabiana* (*P. argyrophylla* × *P. atrosanguinea*, according to Wolf).—*Mars*, dark velvety red.—*M. Daudin*, beautiful amber.—*O'Briana*, pink and salmon.—*P. perfecta*, maroon, shaded lemon.—*P. purpurea*, deep purple.—*P. versicolor*, carmine- and yellow-flaked.—*Victor Lemoine*, light red striped with yellow.—*Wm. Robinson*, mahogany-brown, suffused with orange.

The status of the following trade names cannot be determined: *P. amena*, *P. caucasicum*, *P. cóncolor*, *P. lanuginosa*, *P. minima*, *P. nesiensis*, *P. splendens*.

K. M. WIEGAND.

3159. *Pothos aureus* of the horticulturists. ($\times \frac{1}{4}$)

POTÈRIUM (Greek for *drinking cup*; because the foliage of one species was used in the preparation of a medicinal drink). *Rosaceæ*. Linnæus placed certain rosaceous plants in the genera *Poterium* and *Sanguisorba*, the latter having precedence of publication. Many subsequent authors have united these genera. Focke, however (Engler & Prantl, *Die Natürlichen Pflanzenfamilien*), re-defines the genus *Poterium* to include one species, the *P. spinosum* of S. Eu., allowing the other species to remain in *Sanguisorba*. As thus understood, *Poterium* is monœcious, the lower fls. in the spike staminate, the upper pistillate, the stamens many and hanging, the styles 2, the fr. somewhat fleshy, colored, and inclosed in the calyx, the lvs. pinnate. These plants are known as burnet, although the name applies more correctly to *Sanguisorba* alone. *P. spinosum*, Linn., is a small spiny shrub with nearly glabrous serrate lfts., somewhat downy branches, small greenish fls. in oblong spikes and reddish berry-like fr. It is offered in S. Calif. Grows 3 ft., the branchlets ending in spines. Said to be a very interesting ornamental undershrub. Recently *P. obtusum*, Franch. & Sav. (*P. obtusatum*, Hort. *Sanguisorba obtusa*, Maxim.), has been offered abroad: it is from Japan, said to be the finest of the burnets yet introduced: 3 ft.: lvs. long, pinnate, lfts. about 6 pairs, oblong, rounded at end, serrate, petioluled: fl.-sts. much branched, the crimson spikes about 3 in. long and 1 in. diam. Summer. G.C. III. 59:2. For *P. canadense* and *P. Sanguisorba*, see *Sanguisorba*.

L. H. B.

PÔTHOS (*Potha* is said to be a Ceylonese name). *Aracææ*. Tall-climbing branching shrubs (more or less herbaceous as known in cultivation) of the oriental tropics.

Leaves thick and often shining, entire or lobed, sometimes blotched or variegated: fls. small and perfect, crowded on a spadix, with 6 perianth-segms. and 6 stamens, the ovary 3-loculed and with a rounded or mushroom-like sessile stigma: fr. a 1-3-seeded berry: spathe usually persistent and wide-spreading or deflexed at maturity. *Rhaphidophora* has an oblong or linear stigma.—About 50 species. Several names are in the hort. trade, but not all of them belong to *Pothos*. In fact, the genus *Pothos* is very ill-defined in cult. because species are named before fls. and frs. are known and determinations are often wrongly made. Some of them are to be referred to *Scindapsus* and others perhaps to *Rhaphidophora*. The species of *Pothos* send out cord-like roots that cling to damp walls. For *P. argyrea*, see *Scindapsus pictus* var. For monograph, see Engler, *Das Pflanzenreich*, IV. 23 B (1905). They are warmhouse foliage plants and require the same general treatment as *Philodendron*.

A. Lvs. green, not banded or mottled.

nitens, Bull. Lvs. obliquely ovate-acute, cordate at base, shining purplish green; needs further botanical definition. Malaya.

AA. Lvs. mottled or banded.

aureus, Lind. Fig. 3159. Strong evergreen climber with cordate-ovate-acute lvs., which are variously blotched and mottled with yellowish white, the body color being bright green. Solomon Isl. I.H. 27:381. S.H. 1:334.—The generic position of this plant—which is one of the commonest ones in cult.—is in doubt. It probably belongs to *Scindapsus* so treated by Engler. In a dark place the handsome markings of the lvs. tend to disappear. Branches will grow in water for a time. Prop. by cuttings or layers.

argenteus, Bull. Lvs. obliquely ovate-acuminate, silvery gray, with a deep green margin and a deep green band along the midrib; needs further definition. Borneo.

P. celatocalyx, N. E. Br. = *Monstera latevaginata*.—*P. Lotireiri*, Hook. & Arn. Climbing, branched, with aerial roots: petioles 4-5

in. long, linear, flat; blades decurved, much shorter than petiole, linear-lanceolate, acuminate; spathe $1\frac{1}{2}$ –2 in. long, linear to linear-lanceolate; spadix stipulate, 2–4 in. long, cylindric, green; berries smooth, scarlet, about $\frac{3}{8}$ in. long. S. China. B.M. 7744.

POTHUAVA: *Echmea*.

POT MARIGOLD: *Calendula*.

L. H. B.

POTS. Of the three firms of interest to horticulturists that are eligible to the Century Club because of one hundred years or more in the same business, are A. H. Hews & Co., potters, and J. M. Thorburn & Co., of New York, and D. Landreth & Co., of Philadelphia. This indicates the age of the flower-pot business in this country.

The first entry in the oldest Hews account book reads as follows: Weston, April 19, 1775, Lemuel Jones, to Ware, debtor: 0£ 2s. 8d. From 1788 to 1810, a period of twenty-one years, there is a continuous account. The charges within that entire term cover about as many pages as are now often entered in a day; and the amount in dollars and cents does not compare with single sales of the present time. Through all the years up to 1807 the term "flower-pots" does not once appear, and it is much to be regretted that the first sale of flower-pots and the name of the purchaser cannot be found.

In 1861, after war was actually declared, business conditions were much depressed. The members of the Hews firm felt sure that there would be no demand for flower-pots, they being more of a luxury than a necessity, and that the factory must close. At that time the writer succeeded in securing permission to make his first venture as salesman "on the road." Going first to C. M. Hovey, he secured what was a good order for those times, some 10,000 or more pots for the spring trade of 1862. Not once after that, during the Civil War, was the firm able, in the spring and fall rush, to fill all their orders for flower-pots. It is not that these orders were remarkably large or numerous, but they were beyond the capacity of the firm. In 1866, prices were a third or a half higher than they are today. The firm first got fairly under way with machinery for making small flower-pots in 1869.

Until about 1864 or 1865, common flower-pots throughout the world had always been made by hand on the potter's wheel. There have been, indeed, many different forms of this wheel, but it had always been propelled by hand- or foot-power. When, in the early fifties, a wheel was made to be propelled by the foot, with two sizes of pulleys and a balance-wheel whereby the speed of the wheel was increased in the proportion of three to one, it was thought that perfection had been reached. Much time, though very little money, had been spent previous to the fifties in attempts to make a pot machine. It was left to William Linton, of Baltimore, an experienced practical potter, to perfect and patent the first machine. From him two machines were purchased and the exclusive right to use them in Massachusetts. In a short time great improvements were made on his patent. America was far ahead of Europe in this kind of machinery, as also in improved machinery in general. The machine made only small pots, up to about 5 inches in diameter; and while it had previously taken an experienced man to make his thousand 3-inch pots in ten hours, a smart boy without any previous experience whatever could make 3,000 on the machine in the same time.

When the standard pot was adopted, about twenty-five years ago, the hand-process was practically abandoned in the principal potteries in favor of what is technically called the jigger. This is a revolving disc propelled by machinery. These discs, or jigger-heads, are made of different sizes and fitted with various rings. Plaster molds are made in very large numbers for each size of pot, and the larger standard pots (6- to 12-inch)

are all made at the present time in these molds. The old methods have now passed.

The making of the pot is not its only cost: previous to that comes the preparation of the clay. The hundred years from 1765 to 1865 saw no improvement in the process of preparing it for use. It was ground in a wooden tank or tub, propelled by an ox. The various other processes remained as crude in 1865 as they had been the century previous: the drying, firing, and all connected with the manufacture. The capacity of our flower-pot drying-rooms of today far exceeds the

3160. Pots of various sizes. All are "standard" pots except the rimless one at the right, which is a "rose pot."

entire product of any one year prior to 1865. At that time the custom of using wood for drying and firing pots still continued. It required three cords of white pine and from thirty to forty hours' labor thoroughly to fire a small furnace. Today three tons of bituminous coal will fire five times as much pottery in fifteen hours.

Grades of clay used in the manufacture of flower-pots are almost as numerous as the banks in which they are found, and require many different methods of treatment. To separate the stones from the clay has always been a very perplexing as well as expensive problem. The clay is first plowed by means of a horse and capstan, whereby one horse will do the work of twenty men with picks. This clay is then loaded in dump-carts and carried to the mill, where it is shoveled through a disintegrator, which expels the larger stones and crushes the smaller ones. It then falls on an endless belt and is carried to a revolving drier. This is a western device, with which, by the use of crude petroleum for heat, from 20 to 25 per cent of moisture is evaporated from the clay, and while it passes through a direct blaze of white heat there is sufficient moisture all the time to prevent it from burning. (Burning of the

3161. Fern-pans. A form of pottery useful for small bulbs and many shallow-rooted subjects of which spreading masses are desired.

clay at this stage would make it worthless.) To demonstrate this point beyond question, paper and dry shavings have been passed through with the clay, and they came out without even scorching.

From the drier, the clay goes into large bins, where it must remain twenty-four hours, so that portions of it which have become too dry and hard may absorb the moisture from that not dry enough. From these bins it is carried to whippers, which beat the clay without further crushing the stone. From the whipper it goes to the revolving screens, and thence to the elevators.

The next process is mixing, or, as it is termed, "pug-

ging." This is all done by machinery. From one machine the clay comes out very soft and plastic, to be worked in plaster molds. From the other the clay comes out into hard cubes for the iron molds of the machine. The pot machine and the jigger of today each does the work of six to eight men at the wheel.

The difference in cost between a good and a poor pot is very slight, and if the florist will demand and accept nothing but a first-class pot, a standard in quality as well as size will soon be reached. To be standard in quality a pot must be of clay properly prepared, be of uniform firing, and of a smooth surface inside as well as out. It must also be of right porosity, a condition which can be attained by the proper mixture of clay. Moreover, a machine-made pot should have a smooth rim on the inside, so that the man standing at his bench potting thousands of plants a day, as is being done constantly in large establishments, may have flesh remaining on his thumbs at night. Such a pot must also be able to stand transportation and years of usage if necessary. "Standard" flower-pots, such as are now used by American florists, are shown in Figs. 3160, 3161.

A. H. HEWS.

POTSHERDS. Gardener's name for broken pots and crocks, a material used in the bottom of pots, pans, boxes, and the like, to provide drainage. Coal-clinkers, gravel, and other inert materials, are often used for the same purpose.

POTTING. The first stage in the life of the plant is when the seedling is transplanted from the seed-bed or the cutting is put in the cutting-bench. It is only when either is potted that it can truly be said to take on the dignity of a plant. It is then out of swaddling clothes and enters the ranks of its big brothers and sisters, on the way to making its bow in society; to live perchance in the window of the tenement or on the fire-escape; mayhap to refresh the eye of the patient in the sick-room; or to lose its identity in rows of its fellows in great glass houses where the blossoms are garnered and sent to market; perhaps to take its place in row upon row of its kind and make an arabesque pattern or gay border, and so delight the eye or regale the senses with sweet odors.

The mechanical operation of potting includes also "shifting," i. e., transferring the plant from a small to a larger pot. Repotting signifies the same, generally speaking, as shifting; but speaking technically it means shaking out an established plant and putting it in a pot of the same size or one smaller, according to its needs. The actual operation of potting is very simple, and yet it must be well done to give the young plant a fair start

3162. Potting a cutting. The moment when the thumbs come into play.

in life. Careless potting is responsible for many losses in plants. The larger part of rooted cuttings and seedlings should be potted in 2-inch pots, and it is essential, particularly in the case of rooted cuttings, that it be done at the proper stage of development of the roots. When the roots are from $\frac{1}{8}$ to $\frac{1}{4}$ inch long they may be said to be at their best for potting. If sooner, the plants are not likely to develop so rapidly in the pot as if left in the cutting-bench; if later, they are harder to handle, injury is liable to result, and they do not so readily recover from the shock incident to the change.

The operation of potting as practised in commercial florists' establishments is as follows: The soil having been prepared, the workman places the empty pots at his left hand, the cuttings in front of him, and an empty "flat" to receive the potted plants at his right. With a simultaneous movement he takes an empty pot in his left hand and a handful of soil in his right. He "sets" the pot in front of him, fills it with soil, and while doing so reaches for the cutting, retaining a small portion of soil in his hand. With the index finger of the right hand he makes a hole in the center of the pot of soil, inserts the cutting, drops the portion of soil which he retained in his right hand into the hole, takes the pot between the index and middle fingers of both hands to steady it and obtain leverage, places his thumbs on each side of the cutting and parallel with his body (Fig. 3162), the right on the side away from his body, the left on the other side, and presses evenly and firmly; then shifts his thumbs so that they are at right angles with his body and presses again; transfers the potted plant with his right hand to the "flat," placing it with a little force to level the loose soil on top, reaching for another empty pot with his left hand as he does this, and repeats the movements. It is marvelous how rapidly these motions are made by expert workmen, and the work can be done as well rapidly as slowly when the cuttings are in the proper condition as to root-development already described. There was a time when 5,000 a day of ten hours was considered the maximum, and it is still good work for the average workman. James Markey, an employe of the late Peter Henderson, repeatedly potted 10,000 verbenas cuttings with two boys to assist in taking away the plants as potted, supplying him with empty pots and cuttings, the requisite quantity of soil having been previously placed on the bench. The writer was his only assistant when he made his first great effort at "breaking the record," when he succeeded in potting 7,500 in ten hours. Upon one occasion he potted 11,500 verbenas cuttings in a day of ten hours, which is the highest number ever reached. At a potting contest held in Madison Square Garden in New York city in 1892, George Martin potted 1,373 cuttings in one hour, the material used being arborvitae cuttings without roots. The "standard" pots (Fig. 3160) cannot be handled so rapidly as those without rims, for the reason that the lower edges of the rim are sharp and rough and make the fingers of the workman sore. Consequently the pots without rims are to be preferred.

The essentials in good potting are to put the cutting in the center of the pot and at the proper depth, to firm the soil thoroughly and evenly, and to leave $\frac{1}{4}$ inch, or a little less, between the top of the soil and the upper edge of the pot to receive water.

Included in potting is the care of the plants immediately after being potted and until they have taken root in the pots. First in importance is the "setting" of the plants on the bench; care should be taken that they are "set" perfectly level so that they will hold water. They should be watered thoroughly and shaded as soon as they are set. The best method of shading when large quantities are potted is by the use of lath shutters. These are made by nailing common laths on three parallel pieces of furring strip, allowing 1 inch space between the laths. They may be made any length, 3 feet being a very convenient size. Inverted pots of a sufficient height to clear the young plants make very handy supports for these shutters. During late spring and summer it will be necessary to supplement this method of shading by covering the shutters with paper or muslin, the muslin being preferred. Sew the muslin in 10-yard lengths, giving pieces 2 yards wide. Sprinkle the muslin copiously at intervals as it becomes dry. This care must be kept up for three to six days according to conditions; the shutters should be put over the plants early in the morning, first watering the plants; an hour or so later

the muslin should be put on, provided the sun is shining brightly. After the second day the period for covering the plants should be shortened by putting shutters and muslin on later and taking them off earlier until the plants are sufficiently established to get along without them. An important detail is to have about $\frac{1}{2}$

3163.
Implement
for firming
the soil in
large pots.

inch of sand on the bench to retain moisture and allow for the proper "setting" of the plants. Another very important detail, in case new pots are used, is thoroughly to saturate them with water before filling, allowing sufficient time for the water to evaporate from the surface before using. It is bad practice to work with wet pots, and worse still with wet soil. A good test of the proper amount of moisture in soil for potting is when it molds in the hand only under strong pressure. Another essential, in case old pots are used, is to see that they are clean inside at all events; they should be clean outside as well, but if any old soil is found adhering to the inside of the pot it should be cleaned out and thrown away.

Potting large plants from the open ground, such as carnations, roses, geraniums, and shrubs, is an entirely different operation from the foregoing. These all require pots 5 inches in diameter and over, and sufficient pressure cannot be given with the thumbs properly to firm the soil. It is necessary, therefore, to use a stick about an inch wide, and sharpened down to $\frac{1}{4}$ inch at the end. (Fig. 3163.) The handle should be round, and in a large place where much heavy potting and shifting are done it pays to have some of these sticks in regular tool stock. After the plant is placed in the pot and the latter filled with soil, take the stem of the plant at the surface between the index fingers and thumbs, the other fingers extended down the sides of the pot, lift the pot about an inch and set it back with a smart shock, at the same time pressing the plant down and steadying it; this settles the soil considerably in the pot. Next take the stick described above and run it around the inside edge of the pot twice or so to pack the soil, add more soil to fill up, finish by pressing evenly and firmly the entire surface with the thumbs, allowing $\frac{1}{2}$ inch of space between the surface of the soil and the upper edge of the pots to hold water. What has been said about new and clean pots applies with even greater force to large pots.

The potting of orchids is a radically different operation from the potting of purely terrestrial plants, about which the preceding has been written. Consider cattleyas as an example: being epiphytes, they do not require soil in which to grow; put them in as small pots as possible. The material for potting best suited to these and

3164. Potting an orchid. The pot is cut in two to show the proper conditions inside.

most orchids is fibrous peat and live sphagnum moss in equal proportions, adding a small portion of broken charcoal. If freshly imported pieces are to be potted, cut away all the old dead roots, pseudobulbs and leaves. If the formation of the piece is uneven, it should be cut in two, so as to combine the parts thus separated into a more symmetrical whole, with the growths pointing to the center. Have the pot thoroughly clean, fill it about half with clean "corks" and small pieces of charcoal, adjust the piece in the center of the pot,

distributing evenly any roots which remain; but first spread a layer of moss over the "corks," then press the preparation of peat and moss evenly and moderately firm around the piece and in the interstices between the roots, finishing up high around the center; insert some small-sized stakes at the proper places to support the piece, tie the growth to them, and the job is finished. Fig. 3164 will show better than words can describe how the plant should look after it is potted.

Repotting, when necessary, is almost identical in its details with potting itself. The spring is the best time to do it, even with species which flower in autumn. Carefully remove all the old corks and other

material, so as not to injure the roots, a pointed stick being the best implement for the purpose. Then replace as carefully with new material in a clean pot. The undersigned dwells upon cleanliness repeatedly, for herein lies the great essential in successful plant-growing. Potting orchids in baskets, which sounds paradoxical, is identical with potting them in pots as far as the essential details of manipulation are concerned. The potting of bulbs is discussed under *Bulb*.

"Shifting" is the technical term used in the florist's trade when plants are transferred to larger pots. (See Fig. 3165.) When the plant exhausts the soil in the small pot it must be put in a larger one to maintain growth. The trained eye detects at a glance by the appearance of the plant when it requires a "shift." Those lacking such training can discover it by turning the plant out of the pot and examining the roots. (See Fig. 3166.) If the outside of the ball of soil on the lower portion is well netted with roots as in Fig. 3167, and particularly if most of them have lost the fresh creamy white color of healthy "working" roots, then the plant must be at once shifted, or it will soon reach that stage which is the bane of the careless plant-grower, viz., "pot-bound."

"Knocking out" is the technical term used by florists to describe the turning of a plant out of a pot. The best way to do this is to take the pot in the right hand, invert it in passing it to the left, as the plant should be placed between the index and middle fingers of the left hand, give the pot a smart tap on its rim on the edge of the bench and the ball of soil is separated from the pot; place the plant in a flat ready for the purpose, and repeat. One tap is all that is necessary in ninety-nine cases out of a hundred. It is bad practice to get into the habit of giving a series of taps, as it makes slow work. We are considering now the first shift, i. e., from a 2-inch to a 3-inch pot.

The plants having been knocked out, the next operation is to "shoulder" them. This consists of removing

3165. "Shifting" an established plant into a larger pot.

3166. A plant may be turned out of its pot to ascertain whether it needs a "shift."

the shoulder or edge of the ball of soil with the thumb and forefinger down to where the roots begin. (Fig. 3167.) The object of this is obvious, to remove leached-out soil and supply a fresh, nutritious portion in its place, so as to get the greatest possible advantage from shifting. Everything being made ready, the operator proceeds by

3167. Repotting a sickly plant. The "shoulder" is rubbed off as at *b*, replaced by fresh soil and the whole ball of earth reduced in size. (Only a fraction of the plant's height is shown.)

putting a portion of soil in the bottom of the pot sufficient to raise the ball of soil flush with the edge of the pot. As this is being done, reach for the plant with the left hand and put it in the center of the pot; simultaneously take a handful of soil in the right hand and fill the pot, then grasp the pot between the index and middle fingers of each hand, place the thumbs on each side of the plant at right angles with the body, lift the pot about $\frac{1}{2}$ inch and set it back on the bench with a smart rap, pressing with the thumbs at the same time; change the thumbs to right angles with their former position and press again, then change so as to press where they have not touched already; three pressures of the thumbs and the rap on the bench, and the operation is done. A smart operator with two boys will shift 5,000 plants in ten hours. This amount of work is made possible only by eliminating all unnecessary motions and making them synchronous with each hand in reaching for soil, pot, and plant as described. One hand should not be idle while the other is employed. See Figs. 3168-3172 for good and bad examples of potting.

Be careful in shifting not to set the plants too deep. The tendency of roots is downward, and only enough of the stem to steady the plant in the pot should be in the soil. Plants set too deeply in the pots are easily over-watered, because so much soil is not within the influence of root-action. A few plants which root from the crown, like lilies, should be set deeper than such plants as roses, geraniums, fuchsias, palms, and all plants whose root-action is mainly downward.

Do not give too great a shift at one time; that is, do not attempt to shift from a 2-inch pot to a 5- or 6-inch. As a rule, an inch at a time is best, especially for commercial purposes, where plants are grown to be shipped

some distance. In private places soft-wooded plants may be shifted in spring from 2- to 4-inch pots and from 4- to 6-inch, as the question of shipping does not enter. But it would not be safe even with these to do the same in late fall when growth is slower and the days are growing shorter. Hard-wooded plants, such as palms, azaleas, and the like, and even roses should never be shifted

3168. Good and bad potting. The cutting should be placed in the center.

more than an inch at a time; in fact, it is better not to shift them later than September in any case. The spring is the best time to do it.

Drainage is necessary in all pots over 4 inches and for hard-wooded plants even that size is better drained. This is technically called "crocking," i. e., placing pot-

sherds in the bottom of the pot to allow the quick passage of water and admit air to the roots. Place a large piece over the hole in the bottom of the pot and the remainder in smaller pieces. There are usually enough broken pots around a place to supply the needs. Charcoal is an excellent material for supplying pot-drainage, none better. An inch or so of drainage is sufficient in a 5- or 6-inch pot, 2 inches or so for all sizes above

3169. Too deep.

3170. Too high.

these. A bottom of broken stone, cinders or gravel is essential upon which to stand the pots, as such a stratum accelerates drainage, while at the same time providing a moist surface so beneficial to plants in a greenhouse.

A few words of caution may not be out of place before closing this branch of the subject. Never shift plants while the ball of soil is wet; it should be dry enough to crumble readily to the touch. Never shift into dirty pots; it will pay to clean them, especially the inside. Never shift a pot-bound plant without loosening the soil on the surface of the ball. A few smart raps with the closed fist will do it; or better still repot as now described.

Repotting is necessary frequently when plants have become pot-bound, or when from any cause they appear to require it; such, for instance, as debility from over-shifting, over-watering or neglect of any kind. In such cases the soil should be washed from the roots almost entirely and the plant put into a pot a size or two smaller than it has been growing in, taking care to firm the soil well, and if a shrubby plant prune it back according to its needs and conditions. Shade such plants until danger of wilting is past and water sparingly until new and vigorous growths appear, showing that the subjects have regained their normal health.

There are a few cultural details intimately associated with potting which may with profit be added as a closing paragraph. The high narrow pot shown on the extreme right of the line of pots in Fig. 3160 is frequently used for roses and palms by some, especially for *Cocos Weddelliana*, which makes a long tap-root and which it is almost invariably fatal to break. It is feasible, however, to avoid this if the seeds are sown in 6-inch pots, using 4 inches of clinkers as a bottom. These check the downward growth and induce development of fibrous roots in the soil, so that the tap-root may be cut off below them and the ordinary 2-inch pot used with safety. It is not necessary to use the deep pot for roses in any case. Plants which exceed the diameter of the pot should be given room to allow for development. The best market growers plunge the pots in soil to half their depth, as it is necessary in the spring months because of the rapid evaporation of water. This refers especially to geraniums, fuchsias, heliotropes, petunias, and the like. Care must be taken, however, to lift them occasionally so as to prevent the roots from getting hold in the soil through the hole in the bottom of the pot. Ten inches apart from center to

center for such plants will not be too much if stocky plants well set with good flowers are wanted; and in these days such plants will bring enough in the best markets to pay for the space and trouble. For 2- and 3-inch pots use sifted soil, but for 4-inch and over, soil well broken, but having plenty of fiber from sod in it, should be used. Always water plants thoroughly after

3171. Pot too full.

3172. Good.

shifting so as to soak the soil to the bottom, and do not water again until they show dryness half way down the pot on the outside.

PATRICK O'MARA.

POURRÉTIA: *Puya*.

POURTHIÆA: *Photinia*.

POUTÈRIA (native name). *Sapotææ*. Trees or shrubs with small often short-peduncled fls. in clusters: corolla with 4 rounded lobes and a tube about twice as long; staminodes free, petal-like, borne at the edge of the tube; stamens borne at the base or middle of the tube, becoming free; ovary swollen at base, hairy, 2-4-celled, gradually produced into the long style: fr. a 1-4-seeded berry, hairy or glabrous, occasionally pointed.—About 30 species in Trop. Amer. *P. suavis*, Hemsl. Tree with rather slender flowering branches: lvs. crowded at the ends of the branches, narrow-oblong to lanceolate, about 4 in. long, coriaceous: fls. very small in fascicles borne in the axils of the fallen lvs.: fr. pear-shaped with a thin edible pericarp possessing a delicate perfume. Uruguay. Intro. into gardens abroad.

PRÀTIA (named after Prat-Bernon, with Freycinet's voyage). *Campanulææ*. Slender prostrate or creeping herbs, rarely ascending or erect, sometimes grown for ornament.

Leaves alternate, toothed: infl. axillary, in 1-fl. peduncles; fls. rather small, often unisexual; calyx-tube adnate to the ovary, 5-parted; corolla oblique, split to the base at the back, 2-lipped, upper lip 2-parted, lower lip 3-lobed; stamens 5, 2 lower tipped with short bristles, 3 upper naked; ovary 2-celled: fr. a globose or obovoid berry.—About 30 species, mostly from Austral. and New Zeal., but also in S. E. Asia and S. Amer. Several species seem to be more or less extensively cult. abroad. The genus is very closely related to *Lobelia* and similarly cult., differing from it in the indehiscent more or less succulent fr. They are used both as greenhouse and hardy herbaceous rockwork plants, depending on the species.

angulàta, Hook. (*Lobelia littoralis*, Cunn.). Fig. 3173. Perennial herb, very variable, slender, creeping or prostrate, glabrous or sometimes slightly pubescent: sts. 2-12 in. long: lvs. short-petiolate, orbicular or ovate-oblong to obovate: fls. white with purple streaks: berry globose or broadly ovoid, purplish red. New Zeal. G. 34:757. G.M. 53:897. G.C. III. 47:98. J.H. III. 71:57.—Hardy in England and used as a creeper for

rockwork. Var. *arenària*, Hook. f. (*P. arenària*, Hook. f.). Lvs. larger, obscurely toothed: peduncles very short. Auckland Isls.—Well adapted for shady localities; a quick-growing creeper with many white, star-like fls.

begonifolia, Lindl. Small, creeping, rooting, and pubescent: lvs. cordate-ovate, denticulate: fls. green, marked pink: berry short-ellipsoid, finally smooth, black. India, Malaya. B.R. 1373.—Sometimes grown in the greenhouse.

rèpens, Gaud. Creeping: lvs. petiolate, rather reniform, undulately subrenate: peduncles rather long, axillary, 1-fl.; fls. white with a violet tint. June-Oct. Falkland Isls.—Hardy in England; well adapted for a sunny position on rockwork.

P. ilicifolia, Hort., listed abroad as a charming little creeping plant with evergreen foliage studded through all the summer months with large pure white fls. followed by large lilac-colored berries, and loving a damp spot, is unknown botanically.

F. TRACY HUBBARD.

PRÉMNA (Greek, *stump* of a tree in allusion to the low sts. of most species). *Verbenææ*. Shrubs, subshrubs or trees, sometimes climbing: lvs. opposite, entire or dentate: cymes paniced or corymbose; fls. often polygamous; calyx small, cup-shaped, subequal or 2-lipped; corolla tubular, throat hairy, limb 2-lipped, 5-lobed or subequally 4-lobed; stamens 4, didynamous; ovary 2- or 4-celled, 4-ovuled: drupe small, surrounded below by the calyx, globose or oblong-obovoid.—About 80 species, inhabitants of the warmer regions of the Old World. *P. Gaudichaudii*, Schau. Branches puberulent: lvs. long-petiolate, broad-ovate, short-acuminate, entire: infl. terminal, corymbose panicles, many-fl.; fls. small; calyx short cup-shaped, subbilabiate; corolla subequally 4-lobed. Marianne Isls. This is known as "ahgao" and is said to be extensively used in Guam for the construction of buildings. The following E. Indian species have occasionally been cult. in hothouses abroad: *P. esculenta*, Roxbg., has yellowish white fls. in May and purple fr.: st. grows about 6-8 ft. high; *P. integrifolia*, Linn., with greenish white fls. in July, about 10-12 ft. high, and *P. latifolia*, Roxbg., with dirty white fls. in June, growing about 15 ft. high.

PRENANTHES (Greek words, meaning *drooping blossom*). *Compósitæ*. RATTLESNAKE ROOT. Tall perennial herbs, a few species of which are offered by collectors for use in wild-gardens.

Leafy-stemmed, with dull-colored heads borne in spike-like terminal panicles: lvs. alternate, lower ones

3173. *Pratia angulata*. ($\times \frac{1}{2}$)

petiolate, sagittate, cordate, often much divided; upper ones auriculate and much narrower and smaller: heads 5-30-fl.: achenes terete, 4-5-angled, usually striate.—About 16 species, of which 10 are native of N. Amer. (The N. American forms are by some botanists separated as *Nabalus*.) The species are extremely variable. They are of easy cult. in any good soil, but are very weedy and of little importance horticulturally.

A. *Involucre glabrous.*

B. Heads 5-7-fl.; involucre very narrow, only 1 line thick. *altissima*, Linn. A variable species, mostly perfectly smooth: st. 3-7 ft., slender; lvs. membranous, all stalked, ovate, heart-shaped; fls. greenish yellow; papus straw-colored or whitish. July-Oct. In open or shade, Canada to Ga. and Tenn.

BB. Heads 8-16-fl.; involucre broader, $1\frac{1}{2}$ -3 lines thick.

c. *Pappus deep cinnamon-brown.*

alba, Linn. St. 2-5 ft. high, usually smooth and glaucous or purplish: lvs. angulate or somewhat triangular halberd-form, the uppermost usually undivided; infl. thyrsoid-paniculate; fls. dull white. Aug., Sept. Open woods and sandy soil, Canada to Ga. and Ill. B.B. 3:289. Mn. 3:161.

cc. *Pappus straw-colored.*

serpentaria, Pursh (*Nabalus Fraseri*, DC.). St. usually about 2-4 ft. high, sometimes purple-spotted: fls. purplish, greenish white or yellowish. July-Oct. Ont. to Fla. and Ky. B.B. 3:289.—Little known in cult. and usually only a weed as a wild plant.

AA. *Involucre hirsute-pubescent.*

racemosa, Michx. St. 6 in. to 2 ft. high: st.-lvs. mainly sessile, while they are mostly petiolate in the other species here described: fls. purplish. Aug., Sept. Moist open places, Canada to N. J. and Colo. B.B. 3:291.

F. W. BARCLAY.
N. TAYLOR.†

PRESTÖEA (named after H. Prestoe, of the Botanic Gardens at Trinidad). *Palmaceæ*. Slender dwarf palms with a reed-like, annulate caudex, occasionally grown in the warmhouse: lvs. long and slender-petioled, pinnatisect at the base, upper segms. connate in an oblong blade, 2-cleft at the apex, lower segms. narrow: spathe 2, membranaceous, finally lacerate; spadices short-peduncled, fuscous-pubescent, with strict erect-spreading branches: fls. small, monœcious; male fls. asymmetrical, calyx 3-lobed, minute, petals obliquely ovate, stamens 6, ovary rudimentary; female fls. larger than the male, globose, sepals reniform-rotundate, petals broadly ovate, ovary obovoid-oblong, 1-celled. Three species, W. Indies and Colombia. *P. pubigera*, Hook. f. (*Hyospathe pubigera*, Griseb. & Wendl.). Trunk 10-12 ft. high: lvs. 3-4 ft. long, green with pale nerves, glabrous; lower segms. somewhat distant, linear-acuminate, $1\frac{1}{2}$ -2 ft. long, upper more or less cohering and forming oblong or oblong-linear blades: exterior spathe 2-keeled, 5 in. long, interior 12-15 in. long; lower branches of spadix about 6 in. long, thickened at base, glomerules somewhat distant: fls. minute and sessile. Trinidad.

PRESTÖNIA (named for Dr. Charles Preston). *Apocynaceæ*. Tall climbing pubescent or glabrous shrubs, among which is *P. venosa*, a tender foliage plant once offered in America as *Echites nitans*.

Leaves opposite, with a few well-separated pinnate veins: cymes often densely corymbose or almost umbelliform, pseudo-axillary; calyx nearly 5-parted with 5 entire or lacerated scales inside at the base; corolla salver-shaped with 5 linear erect scales below the throat, which is constricted, 5-lobed; ovary 2-carpelled, ovules numerous in each carpel: follicles hard, erect or divergent at base.—About 30 species, natives of Trop. Amer.

Prestonia venosa is cultivated for the network of crimson veins on its foliage. The plant blooms rarely, and its flowers are inferior to *Echites* or *Dipladenia*. When properly cultivated it makes a charming subject, but if neglected it is as worthless as a weed. It can hardly be propagated by cuttings; the fleshy roots are cut into pieces 1 to 2 inches long. The plant demands a temperature of 85° F., with an atmosphere as moist as possible. Foliage should never be syringed.

Young plants should be raised every season, as older plants become unsightly. The plant was formerly considerably grown, being trained to a balloon-shaped wire trellis. Needs warmth to bring out the markings.—From Lowe's "Beautiful Leaved Plants."

venosa, Mottet (*Echites nitans*, Anders. *Hæmadi-tyon venosum*, Lindl.). Lvs. opposite, ovate-lanceolate, villous beneath: fls. yellow, in pedunculate panicles; corolla-lobes roundish, wavy. St. Vincent in the W. Indies. B.M. 2473. Lowe 58.

F. TRACY HUBBARD.†

PRICKLY ASH: *Xanthoxylum*. **P. Comfrey:** *Symphytum aspernum*. **P. Pear:** *Opuntia*. **P. Poppy:** *Argemone*.

PRIDE OF INDIA: *Melia Azedarach*.

PRIM: *Ligustrum*.

PRIMROSE: *Primula*. **Arabian P.:** *Arnebia cornuta*. **Cape P.:** *Streptocarpus*. **Common P.:** *Primula vulgaris*. **English P.:** *Primula vulgaris*. **Evening P.:** *Oenothera*.

PRÍMULA (*Primula veris*, the "first in spring," was an old appellation of one or more of the species). *Primulacææ*. **PRIMROSE.** Low plants, for the most part herbaceous, mostly spring-blooming but a few kinds used for winter flowering, producing usually clusters of attractive flowers mostly in white, pink, and rose, but sometimes in red, blue, and yellow.

Perennial (plant sometimes monocarpic or blooming but once), with monopetalous salverform fls. in clusters on scapes that arise from a radical cluster of simple entire or lobed lvs.: corolla-tube usually surpassing the 5-toothed or 5-cleft calyx; corolla with 5 spreading lobes, which are commonly notched or retuse at the end and more or less narrowed at the base; stamens 5, affixed to the corolla-tube; ovary 1-loculed, with many ovules on an axile placenta, and 1 undivided filiform style and a capitate stigma, dehiscent by 5-10 valves: bracts of the floral involucre sometimes lf.-like: the fls. of some species are strongly dimorphic or trimorphic,—the stamens and pistils of different lengths in different fls. of the same species (Fig. 3174). See Dar-

3174. Dimorphism in stamens and style of *Polyantha primrose*.

win's work, "The Different Forms of Flowers on Plants of the Same Species;" this polymorphism is associated with cross-pollination. Often the herbage is covered with a loose meal or farina or powder.—Primulas are natives to the N. Temp. zone, only one being known in the cold parts of S. Amer., one in Java, and sparingly in Afr. They are mostly boreal or alpine plants. About a score are native to the colder parts of N. Amer. Twenty-five years ago, Pax (Monographische Übersicht über die Arten der Gattung Primula, Leipzig, 1888, and in Engler's Bot. Jahrbücher, vol. 10), admitted 145 species. Pax & Knuth, in Engler's Das Pflanzenreich, hft. 22 (iv. 237), 1905, describe 208 species and many marked hybrids, and others have been recognized since that time. The number of species now known is upward of 300, with the greatest extension in China (about one-half the species), about 70-75 in the Himalayan region, and the remainder in Japan, N. Amer., Eu., and Eurasia. *P. magellanica* occurs in Patagonia, but is apparently not in cult. The latest horticultural treatment is by S. Mottet, Monographie du genre primevère, Paris, 1915; this work follows the systematic analysis of Pax & Knuth, which also is adopted herewith. The fancier of primules must

also have the proceedings of the Primula Conference held in London in 1913, comprising botanical and horticultural discussions (Journ. Roy. Hort. Soc. 39). The discussion contains a full synonymy of the Chinese and other Asiatic species by Balfour and of European species by MacWatt. For cult. and horticultural descriptions (for England), the reader should consult H. M. Paul, "Handbook of the Hardy Primula," 1911. For evening primrose and Mexican primrose, see *Enothera*.

Notwithstanding the volume of the recent literature, a comprehensive monograph is still lacking, due to the great extension of the genus by contemporary explorers. Further collecting in the Himalaya-Thibet-China region will undoubtedly discover many more forms. The numbers of new species have made it necessary to extend and to recast the sections as defined by Pax & Knuth; but these have not yet been redefined and keyed at once in a connected treatment for the entire genus, and in a compilation like the present it is necessary to spread the Paxian groups as a tentative expedient, even if species of not very close relationship are brought together; in this compilation, the purpose is not so much to show botanical affinities as to make an effort to enable the consultant to identify given species. Even so, it can not be expected, in a genus so large, so variable, and in which so many of the species are recently discovered and little known, that the groups and keys will be always satisfactory to the student. Much change is likely to take place in the definition or recognition of species in the genus, as the many forms are more closely studied. In the present account, the characterizations of the species have been drawn so far as possible from the recent working authorities. The portraits are cited in the text under the names they bear in the different publications, and the author cannot vouch for the authenticity of all of them. The reference R. H. S., in the citation of portraits, is to the Journal of the Royal Horticultural Society.

The date of introduction, given for some of the recent species, is the year in which they were brought into cultivation in Great Britain. The informal notes on culture, under the different species, apply mostly to Great Britain.

Primulas are cool-climate or cool-season plants, mostly spring-bloomers. Many of them grow at very high altitudes, and depend on very special conditions for their perfect development. Several cultural groups of primulas may be recognized: (1) The alpine and sub-alpine section affords some of the most useful plants for rock and alpine gardens. The relatively little attention given to alpine gardens in this country is the reason for the neglect of these charming spring-flowering plants. In recent years, many species have been added to these outdoor primulas and great interest has arisen in them abroad. (2) The polyanthus class, comprising fully hardy spring-flowering plants, suitable for culture under ordinary garden conditions, and always popular in this country. To the same class belong the true cowslip (*P. veris*) and the oxlip (*P. elatior*), but these are rarely seen in our gardens in their pure form. All are easily propagated by division. (3) Yellow-flowered or purple-flowered verticillate-clustered outdoor species, of the *P. imperialis* and *P. japonica* type, some of which are hardy even in the northern states with some winter protection. (4) The true greenhouse species, represented by the old *P. sinensis* (Chinese primrose), the more recent *P. obconica* and the still more recent *P. malacoides*. These are Chinese species. The colors are of the cyanic series. (5) The auriculas of gardens, developed from *P. Auricula*.

In Great Britain, much interest is now taken in new primulas, and very many species are more or less in cultivation, the larger part of them as fancier's subjects. Not many of them have been tried to any extent in this country, and it is commonly assumed that the

American hot summers are against them. Many of them are easily grown from seed and can be carried over in pots in a frame, if they are not hardy or will not withstand the changeable conditions of the open winter. Some of the species do well in open light, but the larger number of the new kinds probably require protection from sun; the species demand an equable supply of moisture. Some of the species mentioned in this country for outdoor growing are *P. Auricula*, *P. Beesiana*, *P. Bulleyana*, *P. capitata*, *P. cortusoides*, *P. denticulata*, *P. farinosa*, *P. frondosa*, *P. japonica*, *P. marginata*, *P. minima*, *P. pulverulenta*, *P. rosea*, *P. Sieboldii*, *P. sikkimensis*, *P. Veitchii*, aside from the English primroses, oxlips, and cowslips (*P. acutis*, *P. elatior*, and *P. veris*), and the auriculas. For the cultivation of the auricula, see Vol. I, page 430.

Cultivation of hardy primulas. (E. J. Canning)

The hardy primulas are not so well known in American gardens as they deserve to be, although their culture is gradually on the increase, and new species are occasionally introduced. Perhaps the best known and most commonly cultivated are those which are native to the meadow lands of Great Britain, central and northern Europe. These are the English primrose (*P. acutis*), the cowslip (*P. veris*), the oxlip (*P. elatior*), and the polyanthus (*P. Polyantha*). They are all simple in their requirements, growing and flowering freely in any good garden soil, and are quite hardy as far north as Massachusetts at least, provided they are not planted in a too exposed or wind-swept position. They are all very attractive when in flower, and they can also be grown in pots and easily forced for flowering in the greenhouse in February and March.

These primulas may be propagated by seeds or division. Seeds may be sown in February in pans or small shallow flats in a mixture of loam, leaf-mold, and sand of about equal proportions, making the surface very fine, pressing the seeds evenly into the soil and covering with about $\frac{1}{4}$ inch of the finely sifted mixture. Place the flats or pans in a warm greenhouse or a temperature of 55° to 60° at night with a rise of 15° by day. In two or three weeks the seedlings should begin to appear. As soon as large enough to handle, they may be pricked out into other flats in a similar soil, and about 2 inches apart each way. By the middle of May they will be good plants, and since they do not flower the first season, they may be planted out in lines in some sheltered part of the garden till September, when they may be lifted and planted where they are wanted to flower in spring. Also those intended for flowering in the greenhouse should be potted at this time. Seeds may also be sown in a coldframe in April or May, scattering them very thinly in shallow drills, watering and keeping free from weeds in the summer, and transferring them in September to the position in the garden where they are to flower in the spring.

Propagating by division is practised when the plants become rather large or to perpetuate some very fine variety. It consists simply in dividing the plant or clump into two or more parts and replanting again. September is the best month to do this.

The cowslip, oxlip, and English primrose are excellent subjects for massing or naturalizing in open woodland, on sheltered banks, or any position where they are not too shaded, and where they can be left undisturbed for several years. They are almost indispensable in gardens where a spring display of flowers is wanted. A light mulching with stable-manure, or in very cold gardens, a few branches of hemlock or pine, is all the winter protection they need.

Other hardy primulas not so well known as the above, but even more beautiful and showy and some of them of larger growth, are species from China and Japan, some of them from high altitudes in the Himalaya

mountains, and others from boreal and mountainous regions of Europe and North America. From Japan, *P. japonica* and *P. Sieboldii* are the best. From China, *P. pulverulenta* and the recently introduced species, *P. Bulleyana* and *P. Beesiana*, are large and showy, producing their bright flowers in whorls, *P. Beesiana* having from five to eight whorls with an average of sixteen flowers in a whorl. From experience and observation, the writer finds that they must have a deep rich moist soil in a sheltered place, with an eastern aspect, or where they are shaded during the warmest part of the day. A low moist nook in a properly constructed rock-garden is an ideal place for them.

The high mountain and northern species, *P. cortusoides*, *P. denticulata* and the variety *cachemiriana*, *P. rosea*, *P. farinosa*, *P. mistassinica*, and *P. Auricula*, require a rich moist soil with an eastern aspect in a rock-garden for their successful culture. It is not so much the cold of the winters as it is the heat and drought of our summers that makes their cultivation difficult.

Most of them flower through the months of May and June. They are all propagated by seeds which may be sown in flats in a cool shaded frame as soon as ripe or about the end of July, wintering the seedlings in a cool greenhouse or frame the first winter, and planting out in the rock-garden in spring; or seeds may be sown in February in a warm greenhouse as recommended for the English primrose, but keeping the seedlings in flats in a shaded frame till September before planting in the rock-garden. A light dressing of decayed stable-manure carefully placed between the plants as winter comes on and a few hemlock or pine branches to protect them from the sun in winter are beneficial.

While this last group of primulas may never become so popular in this country as they are in the cool and moist climate of England, yet, for anyone who can provide the conditions, they are well worth growing.

Commercial culture of florist's primulas. (E. A. White)

Primulas have long been regarded as important by commercial plant-growers. Their compact dwarf habit of growth and their freedom of flower production make them especially desirable. They have never been used extensively as cut-flowers, yet the flower-clusters of some species, such as *P. obconica* and *P. malacoides*, lend themselves well to artistic arrangement and are sold in limited numbers in the larger cities, usually in bunches of twenty-five sprays. *P. Polyantha* also produces sprays of blooms which are particularly attractive in spring when cut and arranged in a somewhat formal manner similar to bunches of trailing arbutus. The species most generally grown under glass for potted plants are *P. obconica*, *P. sinensis*, *P. kewensis*, and *P. malacoides* (fairly primrose); *P. Forbesii* (the baby primrose) is still sometimes grown.

While *P. sinensis* in its varying varieties is still grown as a potted plant to a considerable extent, it is of less importance commercially than are *P. obconica*, *P. kewensis*, *P. malacoides*, and *P. floribunda*. *P. sinensis* var. *stellata* seems more in demand than the type. When taken from the greenhouses to a dwelling-house or a flower-store, the individual flowers of *P. sinensis* soon fade and the plants become unsightly. Retail dealers speak of them as "poor keepers." The most desirable varieties of *P. sinensis* are Crimson King, Pink Beauty, Reading Blue, Orange King, The Czar, The Duchess, Coral-Pink, Princess May, and Royal White. In the stellata group, White Star, Pink Star, Light and Dark Blue Star, and Giant Red Star are most frequently grown. *P. malacoides* and *P. obconica*, the latter in its several varieties, Kermesiana, Fire King, and Giant Red are probably the most important present-day primulas.

Primulas are usually propagated yearly from seed. When very large plants for exhibition purposes are

desired, the plants may be carried over a second year. Young plants are usually more productive of blooms, hence are more desirable. Seeds must be fresh. Primulas may also be propagated from cuttings.

When large plants are desired for Christmas, the seed is sown in January. Later sowings may be made in February and March. Seed-pans should have a layer of broken crock in the bottom for drainage, and a little coarse material is placed above this. The seed-pan is then filled evenly full with a mixture of equal parts of leaf-mold and sand. This is compacted slightly, being careful to have the surface even. The top of the soil should not be over $\frac{1}{8}$ inch below the top of the rim of the pan. If lower than this, the confined atmosphere about the seedlings may cause an attack of the "damping-off" fungus. The seeds are then sown evenly and thinly over the surface and a thin covering of one-half finely sifted leaf-mold and sand, thoroughly mixed, is sprinkled evenly over the top. The seed-pans are then sprinkled with a fine spray, covered with glass, and placed in a partially shaded spot. As soon as the seedlings germinate, the glass should be removed. The germination period in the life of primulas is a critical one, and temperature, light, and moisture require particular attention.

When the seedlings have developed about three leaves, they should be transplanted. Small flats are preferable to pots. The seedlings are spaced about $1\frac{1}{2}$ inches each way. A soil compost of equal parts of leaf-mold and sand is excellent for the first transplanting. When the seedlings have developed about five leaves they should be potted into 2- or $2\frac{1}{4}$ -inch pots. Care should be taken in this first potting and in subsequent repottings not to set the plants too deeply in the soil, as it causes the lower leaves to decay. The crown should be even with the soil. If it is above the soil, the plants will be inclined to topple over as they reach maturity and it may be necessary to stake them. At no time should the young plants be allowed to become pot-bound. Any check in their development during the rapid-growing period prevents the perfection of the plants. They should be repotted several times and the soil made a little richer each time by the addition of well-rotted cow-manure and bone-meal.

About the tenth of June primulas may be put into a frame out-of-doors. A shaded glass sash should be put over them and raised about 2 feet above the frame. This gives excellent air circulation about the plants and makes them strong and stocky. In August the plants are repotted for the last time. Six-inch pots are mostly used. The soil at this time should be considerably heavier and richer than previously. A mixture of three parts leaf-mold, two parts finely chopped sod, one part sand and one part well-rotted cow-manure with a liberal sprinkling of bone-meal makes an excellent soil for primroses. Watering should be carefully attended to in the summer months.

About the middle of September the plants should be brought into the greenhouse and placed in a coolhouse where a night temperature of about 45° can be maintained. This low temperature induces a stocky healthy growth and subsequently large strong flower-spikes. After bringing the plants into the greenhouse, they should become accustomed gradually to full sunlight. After a few weeks in a coolhouse, the temperature may be gradually raised to 50° or even 60° ; but the plants are better if grown in a low temperature.

KEY TO THE SECTIONS OR GROUPS.

- I. Plants of hybrid origin, of many kinds, more or less in cult. I. HYBRIDS, p. 2786.
- II. Plants of specific difference, representing wild or native species of *Primula*.
 - A. Young lvs. involute (edges turned inward).
 - B. Lvs. mostly thick or coriaceous: fls. umbellate: bracts of involucre usually not lf.-like. II. AURICULA, p. 2787.
 - BB. Lvs. thin or membranaceous: fls. in superimposed whorls or verticels: bracts of involucre leafy. III. FLORIBUNDA, p. 2791.
 - AA. Young lvs. revolute (edges turned backward).
 - B. Lvs. lobed and distinctly petioled, the lobes dentate or crenate. IV. SINENSES, p. 2791.
 - BB. Lvs. not lobed or only indistinctly so.
 - C. Calyx leafy, strongly accrescent (increasing in size) after flowering. V. MONOCARPICÆ, p. 2795.
 - CC. Calyx little or not leafy or accrescent: plant stoloniferous. VI. MINUTISSIMÆ, p. 2796.
 - CCC. Calyx as in cc.: plant not stoloniferous.
 - D. Fl. solitary on a bractless scape. VII. OMPHALOGRAMMA, p. 2796.
 - DD. Fls. usually many (sometimes solitary) on a bracted scape.
 - E. Foliage usually pilose or pubescent.
 - F. Blossoms distinctly pedicellate (each one on a stalk).
 - G. Lf.-texture coriaceous or nearly so, strongly rugose.
 - H. Length of lvs. 4 in. or less. VIII. BULLATÆ, p. 2796.
 - HH. Length of lvs. 4 in. or more. IX. CAROLINELLÆ, p. 2797.
 - GG. Lf.-texture thin or membranaceous, rugose.
 - H. Base of lf.-blade cordate; petiole distinct. X. FALLACES, p. 2797.
 - HH. Base of lf.-blade usually attenuate into a petiole. XI. VERNALES, p. 2797.
 - FF. Blossoms sessile or very short-pedicellate.
 - G. Bracts of involucre short and broad. XII. SOLDANELLOIDEÆ, p. 2799.
 - GG. Bracts lanceolate or subulate. XIII. CAPITATÆ, p. 2800.
 - EE. Foliage usually glabrous or only minutely pubescent.
 - F. Bracts of involucre gibbous or saccate at base. XIV. FARINOSÆ, p. 2801.
 - FF. Bracts not gibbous or saccate.
 - G. Base of lf.-blade cordate; petiole distinct: caps. cylindrical.
 - H. Corolla funneliform. XV. CORDIFOLIÆ, p. 2804.
 - HH. Corolla cylindrical. XVI. SREDINSKYA, p. 2804.
 - GG. Base of lf.-blade gradually narrowed into petiole: caps. globose.
 - H. Umbel 1-2-fld.: lvs. somewhat coriaceous: plants low, sometimes very small. XVII. TENELLÆ, p. 2804.
 - HH. Umbel several- to many-fld.: lvs. either petioled or narrowed into a winged base, the midrib very wide: plant mostly low, but scape sometimes long. XVIII. PETIOLARES, p. 2805.
 - HHH. Umbel several- to many-fld.: plant tall.
 - I. Blossoms pedicellate, in superimposed umbels: lvs. membranaceous or papery, serrulate or denticulate. XIX. CANKRIENIA, p. 2805.
 - II. Blossoms very short-pedicelled or nearly sessile, mostly in simple umbels: lvs. usually coriaceous, obtusely denticulate. XX. CALLIANTHÆ, p. 2807.

- ggg. Base of lf.-blade narrowed into a winged petiole, the lf.-margin entire or denticulate: caps. cylindrical. XXI. NIVALES, p. 2807.
- gggg. Base of lf.-blade cuneate or rounded, contracted to petiole, the margins usually coarsely toothed toward apex: caps. cylindrical or ovoid. XXII. MACROCARPÆ, p. 2808.

I. HYBRIDS AND REPUTED HYBRIDS.

Several hybrid primulas have attained more or less prominence in cult. aside from those in the Vernaes group (*P. elatior-veris-acaulis* set), and they are briefly described here; *P. kewensis* is apparently the best known of them in cult. In a genus so vast and abounding in beautiful forms, many good cultural hybrids are to be expected, although the number of artificial ones is surprisingly small considering the number of species and the length of time some of them have been in cult. For an account of Primula hybrids in nature, see Farrer, Journ. Roy. Hort. Soc. 39:112-28; also the monograph by Pax & Knuth.

A. Fls. yellow.

1. *kewensis*, W. Wats. (*P. floribunda* × *P. verticillata*). Fig. 3175. A hybrid that appeared in one of the houses at Royal Botanic Gardens, Kew, in 1897, blooming in 1899: it has some of the mealiness of *P. verticillata* and the general appearance of a robust form of *P. floribunda*: lvs. in rosette, 6-8 in. long and 1½-2 in. wide, obovate-spatulate, tapering to a petiole-like base, margins wavy and dentate: scapes many, 1 ft. high, slender but erect, glabrous, bearing 2-4 whorls of 6-10 bright yellow fragrant fls. on slender pedicels: bracts large, dentate: calyx campanulate, the lobes regular and acute; corolla-tube 1 in. long, the limb ¾ in. across, the lobes nearly circular and notched. G.C. III. 27:195. R.H. 1908:400. Gn. 59, p. 198; 64:10. G.M. 43:232; 51:320. G. 26:99. Gn.M. 15:18. Gn.W. 20:249; 21:214.—A var. *farinosa*, Hort., is listed, the sts. and foliage covered with silvery white powder. *P. kewensis* is a good winter bloomer of long season, and a desirable companion for *P. sinensis* and *P. obconica*; requires the general treatment of *P. obconica*.

AA. Fls. not yellow, in shades of red or purple, sometimes white.

B. Plants of the Auricula section or type.

2. *admontensis*, Gusm. Said to be a hybrid between *P. Auricula* and *P. Clusiana*, but probably a *P. Clusiana* form or *P. Clusiana* × *P. minima*: described by Paul as a very dwarf-growing plant, hardly 3 in. high: fls. large, purplish lilac, in June: lvs. fleshy, round-oval, evergreen. Admont, in Steiermark, Austria.—Said to thrive in full sun in limestone soil.

3. *Arctötis*, Kerner. One of the numerous hybrid progeny of *P. Auricula* and *P. hirsuta* (see *P. pubescens*, No. 20): as a garden plant, said to have acquired some of the characteristics of both parents: fls. lilac-purple or white, in May and June, on scapes 4-5 in. high.—Succeeds in partly shady places in sandy loam; natural hybrid.

4. *Berninæ*, Kerner (*P. hirsuta* × *P. viscosa*). Three to 4 in.: fls. large, rosy purple, on short sts.; April, May.—A natural hybrid.

5. *Biflora*, Huter. Natural hybrid of *P. glutinosa* and *P. minima*: fls. in 2's, deep rose-colored, rising scarcely more than .1 in. above the foliage, early.—Requires partial shade and a well-drained position.

6. *Bilëkii*, Hort. A natural form from the Tyrol, probably hybrid of *P. minima* and *P. hirsuta*: very small, resembling *P. minima* but slightly taller, bearing profusely of large pale rose-colored fls.; late spring and early summer.

7. *Böwlesii*, Farr. (*P. pedemontana* × *P. viscosa*). A natural hybrid, usually larger than *P. pedemontana*, the upper face of lvs. densely glandulose, scale longer, pedicels longer and densely glandular, the umbel few-fl. and 1-sided; smaller than *P. viscosa*, the fls. wider, the lvs. and pedicels with more or less rufous glands: intermediate between the parents, with which it was found. Intro. 1911.

8. *discolor*, Leyb. (*P. Pörtæ*, Huter). Natural hybrid of *P. Auricula* × *P. ænensis*: said by Paul to be "a charming plant for sunny places on the rockery." 3-4 in.: fls. lilac-purple with silvery white eye; April-June.

9. *Fächinii*, Schott. Natural hybrid of *P. minima* × *P. spectabilis*: said to inherit the strength and vigor of *P. spectabilis* and the free-flowering qualities of *P. minima*: 3 in.: fls. rosy purple, usually 2 or 3 to each

3175. *Primula kewensis*. (× ½)

st.; May, June.—Paul says that it is essentially a rock-plant, succeeding in shady positions as well as in full sun in light sandy soil. G.W. 15, p. 273.

10. *Floerkeana*, Schrad. Natural hybrid, *P. glutinosa* × *P. minima*: an excellent plant, intermediate between the parents: 3 in. or less: fls. bright rose, in heads.—Succeeds best in partly shaded places in rockery, in peaty loam.

11. *Försteri*, Stein. Natural hybrid of *P. hirsuta* × *P. minima*: resemblance closer to *P. minima*, but with 2 or 3 larger fls., which are rosy purple with white throat, carried 3-4 in. above the foliage. Brenner Alps. G.C. III. 52:490.—Prefers loamy soil in partial shade; blooms in early spring and also in autumn.

12. *Goëbelii*, Kerner (*P. Goëbelii*, Hort.). Natural offspring of *P. Auricula* × *P. hirsuta*: 4-5 in.: lvs. stiff and fleshy, in close rosettes: fls. brownish violet;

May-July.—Sunny position in rockery. See *P. pubescens*, No. 20.

13. *Heëri*, Bruegg. Natural hybrid of *P. hirsuta* and *P. integrifolia*: a showy dwarf tufted plant, with loose heads in June of bright purple fls.—Shady place in the rock-garden, in light loam.

14. *Hüteri*, Kerner. Natural offspring of *P. glutinosa* × *P. minima*: very small, scarcely more than 1 in. high; fls. rather large for size of plant, deep violet, borne singly; May, June. Tyrol.—Of good constitution; prefers slightly shaded place.

15. *intermedia*, Hort. Several applications are covered by the name *P. intermedia*: described and illustrated in G. 8:259 as “one of the most beautiful of the members of a very large family, and closely resembles the alpine auriculas, its fls. being purplish crimson, with a conspicuous yellow eye, and produced on stout sts, in crowded clusters that overtop the foliage.” fragrant. April.—The garden plant under the name *P. intermedia* is probably one of the natural hybrids of *P. Clusiana* and *P. minima*.

16. *Këllereri*, Widm. Natural hybrid of *P. hirsuta* and *P. minima*: very dwarf, but sturdy: fls. pale rose-colored, in trusses; May, June. Tyrol.—Slightly shaded positions in a light sandy soil.

17. *Kërneri*, Goeb. & Stein. *P. Auricula* × *P. hirsuta*, a natural hybrid (see *P. pubescens*, No. 20): 4–5 in., hairy: fls. rose-lilac, with yellowish white eye; April, May.—Sunny and dry positions in rockery.

18. *Muretiàna*, Moritz. (*P. Mureti*, Charp.). Natural hybrid of *P. integrifolia* and *P. viscosa*; a similar cross is *P. Dinyàna*, Lager, which may be the preferable name for the group: lvs. pale green, in rosettes, stiff and fleshy: scapes 4–5 in.: fls. bright purple, in clusters; April, May.—Lightly shaded places in rockery.

19. *Peyritschii*, Stein. Natural hybrid of *P. Auricula* and *P. hirsuta* (see No. 20): 4–5 in., producing many crimson-purple fls. in large clusters; March-May.—Strongly recommended for partly shaded places in well-drained soil in the rock-garden.

20. *pubescens*, Jacq. Several natural forms of *P. Auricula* × *P. hirsuta* are included under the name *P. pubescens*; here may be referred the variants represented by the names *P. helvetica*, Don, *P. rhætica*, Gaud., *P. Arctotis*, Kerner, *P. Goeblii*, Kerner, *P. Kernerii*, Goeb. & Stein, *P. Peyritschii*, Stein, all probably differing in minor characters and garden value. *P. pubescens* is a hardy plant, according to Paul, and easy to grow in both sun and shade, if it has a well-drained place: 3–4 in.: fls. rosy crimson with white eye; May, June. *P. pubescens alba* = *P. hirsuta* var. *nivea* (No. 41), a very free-flowering plant, with large snow-white fls. which make an excellent display against the rosettes of stiffish lvs. Gn. 75, p. 88. G.L. 16:95.

21. *rhætica*, Gaud. One of the *P. pubescens* forms (No. 20), hybrid of *P. Auricula* and *P. hirsuta*: lvs. white-mealy: scape 3 in. above foliage, mealy: fls. large, clustered, brilliant violet-purple; May-July, flowering continuously in a sunny place in the rockery.

22. *salisburgënsis*, Floerke. Natural form of *P. glutinosa* × *P. minima*, perhaps not in cult.: lvs. cuneate, strongly 7–9-toothed toward the top, serrate at summit; scape not glutinous: fls. rose-colored.

23. *Stürrii*, Schott. Natural hybrid of *P. minima* and *P. villosa*: dwarf and tufted but vigorous and free-flowering: fls. large, bright rose-purple, borne singly; April-June.—For shaded places in the rock-garden.

24. *venusta*, Host (*P. Jelénkæ*, Gusm.). Natural hybrid of *P. Auricula* and *P. carniolica*: habit of *P. carniolica*, but the lvs. and calices sometimes more or less white-mealy: vigorous and hardy; 3–4 in., forming large spreading rosettes: fls. fragrant, red to brownish

rose or purple; April-June.—For half-shady places in the rock-garden.

25. *Venzdi*, Huter (*P. adulterina*, *P. cridalensis*, *P. micrantha*, and *P. valmenona*, Gusm.). Natural hybrid of *P. tyrolensis* and *P. Wulfeniana*: large or small, mostly a strong and free grower with lvs. in rosettes: scapes 3–4 in. above foliage: fls. in loose heads or clusters, large, lilac-purple.—For half-shady places in the rock-garden.

26. *vochinënsis*, Gusm. One of the natural forms of *P. minima* × *P. Wulfeniana*: robust, 4–6 in., or much less in the wild: lvs. oblong, usually few-toothed but rarely entire: fls. in trusses, bright red, spring to late summer.—Said by Paul to be serviceable for chalky soils in dry sunny places.

BB. Plants of various sections, probably not of the Auricula group or kind.

27. *Aréndsii*, Hort. Arends. Said to be a hybrid between *P. obconica* and *P. megaseæfolia*, “in general appearance similar to a glorified *P. obconica*”: fls. rich lilac-pink in color, in many-fl. umbels: lvs. more nearly resembling those of *P. megaseæfolia*, the petioles exceedingly hairy.

28. *Briscoei*, Hort. Veitch. (*P. Bulleyana* × *P. japonica*, of garden origin). Habit of *P. japonica*, but with paler lvs. and more crimsoned midrib, the infl. inheriting to some extent the powdery character of *P. Bulleyana*; the scapes and fls. are said also to resemble *P. pulverulenta*; purple-fl. (?).

29. *Förtunei*, Vatke, is undetermined. The plant in cult. is described and figured in G.C. III. 53:238 as a perennial with coarsely dentate lvs., with very little farina: scapes about 3 in. high, terminating in a loose head of fls. which suggest those of *P. farinosa*: fls. about ½ in. diam., bluish lilac, with primrose-yellow eye. “Flowering early in the year, it is a useful subject for the alpine house, and the blooms last fresh for a considerable period.” Fl. Mag., X. 7 (1860). J.H. III. 63:343. Gn. 69, p. 210; 77, p. 182. G. 37:279.—Rare in cult.; at Kew grown recently from stock contributed in 1905 by Col. Beddome. Perhaps hybrid of *P. denticulata* and *P. farinosa*. Said to be suggestive, as it grows, of *P. frondosa*.

30. *Lindsayi*, Hort. Hybrid, parentage not recorded, with deep crimson fls. with purplish yellow eye: “a pretty plant with neat foliage and fls. of a kind of deep crimson and a purplish yellow eye.” Named for R. Lindsay, Edinburgh.

31. *Silva-Tarouçana*, Fedde (*P. pulverulenta* × *P. Cockburniana*, a garden hybrid). Known also as Unique: foliage much like that of the common primrose, the blade decurrent on the petiole: fls. turkey red, in tiers, the calyx and pedicel white-farinose. A fine garden plant. G.C. III. 41:391.

32. *Sueptitzii*, Gusm. (*P. rosea* var. *grandiflora* × *P. cashmeriana*, a garden hybrid). Fls. light blue, in April, on strong sts., and strong plants: sometimes bloom in autumn: hardy and free-flowering.—Intro. by P. Süptitz, Bad Lauterberg, Germany.

33. *Tewfikiana*, Hort. Vilm. Garden hybrid of which one of the parents is supposed to be *P. Bulleyana*: a vigorous grower, producing infl. 2 ft. high: fls. in several tiers, salmon-rose with yellow eye: fertile.

II. AURICULA.

Fleshy-lvd. or coriaceous-lvd. species from the Alps, Pyrenees, and other high mountains of Eu.: fls. in umbels (rarely varying to nearly or quite single): bracts not foliaceous or leafy.

A. Fls. yellow (much modified in color in cult. forms, particularly in No. 34).

34. *Auricula*, Linn. (*Auricula lutea*, Opiz). AURICULA. See p. 430 and Fig. 440, Vol. I, and also for

cult. Low, with a radical rosette of thick obovate-cuneate glabrous or pubescent mealy lvs. 2 or 3 in. long, which are often crenate on the upper part: scape 1-8 in. high (sometimes nearly or quite wanting), usually exceeding the lvs.: fls. in an umbel, sometimes as many as 20, bright yellow and fragrant or inodorous, short-stalked, subtended by minute oval mealy bracts, the segms. obovate-cuneate and emarginate; stamens dimorphous.—This description represents the wild form as understood by J. G. Baker in B.M. 6837. "It is one of the most widely spread of all the species," Baker writes, "as it extends in a wild state from Dauphine and the Jura on the west through Switzerland to Lombardy, the Tyrol, Hungary, and Transylvania." In cult., the plant has run into fls. of many colors. It is possible that some of these forms are hybrid progeny with related species. Baker writes: "What the relation is of this widely spread wild type to the multiform races of the garden *Auricula* is a subject that still remains to be fully worked out." The cult. forms are of two groups,—those having farina on the lvs. and those without it. Var. *albocincta*, Hort. Lvs. densely farinaceous, white-margined. The wild form of the species is little known in cult. MacWatt writes that "by nature it flourishes best where it is most at home, amongst the limestone rocks of the Alps, the Apennines, and the Carpathians. In the wild state the flowers are comparatively small, but under cultivation the scape often carries a big head of large-sized flowers." Var. *ciliata*, Koch (*P. ciliata*, Moretti. *P. Bálbisii*, Lehm. *P. bellunensis*, Vanzo), has lvs. not farinose, cartilaginous-margined, more or less glandular-pilose, the edges densely long-ciliate: fls. scentless. Var. *Obristii*, Beck (*P. Obristii*, Stein. *P. similis*, Stein. *P. Bálbisii*, Beck). Lvs. silvery green, not mealy, more or less glandular-hairy, the margin cartilaginous and ciliate: fls. fragrant, yellow, the calices and pedicels mealy; May-July.—For dry sunny edges or rocks.

35. *Palinūri*, Petag. Rhizome woody and widely spreading: lvs. large, often 8 in. long and 3 in. wide, obovate or oblong, fleshy and pliable, light green, not farinaceous, dentate, narrowed into a petiole which is sometimes elongated: scape surpassing the lvs., farinose above, bearing a many-fld., even to 40-fld., umbel: fls. pedicellate, drooping to one side, the floral bracts leafy and farinose; calyx densely white-farinose, campanulate at top, deeply cut into sharp-pointed lobes; corolla deep yellow, standing well out of the calyx, the lobes emarginate: caps. equaling or exceeding the calyx. S. Italy in the Apennine region. B.M. 3414. G.C. III. 41:18. Gn. 76, p. 227. G.M. 55:381.—A striking species with a cowslip odor, blooming in England in May; it is advised in England to grow it in good loam to which peat and sand have been added; in cold districts it is to be kept under glass, with plenty of light and air, in winter; does not bloom until it has attained good size.

AA. Fls. rose, violet, purple, or bluish.

B. Lvs. entire, coriaceous, cartilaginous-margined: bracts narrow and long: fls. rose-colored.

C. Foliage pellucid-punctate and viscid.

36. *spectabilis*, Tratt. (*Arbitia spectabilis*, Link). A low plant (3-4 in.) with stiff, glossy green oblong or rhomb-oblong viscid entire lvs. that have a pronounced cartilaginous margin or edge, acute or subacute, deeply pitted on the upper surface: scape equaling or exceeding the foliage, bearing a 1-7-fld. umbel: bracts linear and acute, usually reddish: fls. mauve-colored; calyx tubular-campanulate, with lanceolate obtuse lobes, minutely glandular; corolla exceeding the calyx, about 1 in. across, widened above, the lobes obcordate. Alps. R.H.S. 39:105.—A showy species, requiring a shady place in light soil in the rock-garden; worthy of attention.

CC. Foliage not pellucid-punctate or viscid, green or glaucous.

37. *glaucescens*, Moretti. A vigorous glabrous species, not farinose: lvs. 1-4 in. long, lightly glaucous and blue, stiff, shining, narrowly oblong or lanceolate, acute, broadly cartilaginous-margined: scape 2-5 in. high, somewhat exceeding the foliage, bearing a 2-6-fld. umbel: bracts leafy, usually reddish, linear: fls. rose, lilac, or purple; calyx tubular, cut to middle or below, the lobes lanceolate or oblong and acute or somewhat obtuse; corolla funnel-form, about 1 in. across, with obcordate lobes: caps. oblong, included in calyx. Alps. Gn. 61, p. 360. R.H.S. 39:105. Var. *calycina*, MacWatt (subsp. *calycina*, Pax & Knuth. *P. calycina*, Duby). Stouter: lvs. and calyx large, the latter cut beyond middle with acute lobes: corolla-limb about $\frac{3}{8}$ in. across. G.W. 15, p. 271. G. 36:273. Var. *longobárda*, MacWatt (subsp. *longobárda*, Pax & Knuth. *P. longobárda*, Porta). Smaller: lvs. and calyx small, the latter cut to middle with acute or obtuse lobes: corolla-limb scarcely $\frac{3}{8}$ in. across.

38. *Wulfeniana*, Schott. Spreading tufts: lvs. 1-2 in. long, stiff, lanceolate to oblong and elliptic, not viscous, shining, dark green, margined and minutely glandular: scape about 2 in. high, equaling or surpassing the foliage, bearing 1-3 fls.: bracts linear, usually reddish: fls. rose-colored; calyx tubular, glandular, more or less purplish, with ovate-obtuse lobes; corolla with white throat, the limb funnel-form and about 1 in. across, the obcordate lobes deeply emarginate: caps. included in calyx. Alps, chiefly Austrian. Gn. 61, p. 429.—Very early blooming in cult. and not difficult to grow.

39. *Clusiàna*, Tausch. Foliage lighter in color than in No. 38, the lvs. stiffish and somewhat shining, scarcely viscid, ovate or oblong, acute or obtuse, entire and the margin narrowly cartilaginous: scape sometimes 4 in. or more high (usually 6-7 in. under cult.), glandular, 1-6-fld.: bracts lanceolate or linear, more or less purplish: fls. rose-colored or lilac; corolla-lobes bifid rather than emarginate. Austrian Alps. G.W. 15, p. 271. R.H.S. 39:105.—Of easy cult. in a slightly shaded place.

BB. Lvs. serrate or dentate (sometimes only subserrate or, as in No. 40, perhaps entire), coriaceous or fleshy: bracts various: fls. rose-colored, bluish, or violet.

C. Foliage not farinose but reddish glandular-hairy, at least on margin (with a reddish exudate).

D. Glandular-hairy on margins of lvs. only.

40. *pedemontàna*, Thomas. Lvs. ovate or oblong-lanceolate, acute or obtuse, dentate or sometimes practically entire, shining, the margin densely glandular red-ciliate, otherwise glabrous or nearly so: scape surpassing the lvs., about 6 in. high, glandular, bearing 1 to many rose-colored or rarely white handsome fls.: bracts ovate and obtuse, scarious: calyx tubular-campanulate, glandulose; corolla minutely reddish glandular, the throat white, limb about 1 in. across, the lobes obcordate. Graian and Cottian Alps. B.M. 5794. Gn. 61, p. 397; 72, p. 166.

DD. Glandular-hairy on both surfaces of lvs.

E. Fls. long-pedicelled (pedicels usually $\frac{1}{8}$ - $\frac{1}{2}$ in. or so in length): scape mostly shorter than the lvs.

41. *hirsuta*, All. Lvs. broadly obovate or rhomboid, varying rarely to somewhat cuneate, obtuse, very viscid, with yellow, orange, or reddish glands, toothed toward the apex or throughout: scape glandular, often shorter than lvs., to about 3 in. high, bearing 1 to many fls. on filiform pedicels: bracts broadly ovate and obtuse, scarious: fls. lilac, rose, or white; calyx broad-campanulate, glandular; corolla-limb 1 in. or less across, with obcordate emarginate lobes: caps. included in calyx. Pyrenees, Alps, Apennines. B.M. 14 (as *P. villosa*); 1922 (as *P. decora*). Gn. 61, p. 359. R.H.S. 39:105.

The species is said to be grown sometimes as *P. viscosa*. Runs into var. *angustata*, Widm., with oblong lvs. gradually narrowed into a petiole, and rose-colored fls.; var. *exscapa*, Pax, scape very short or none, and lvs. nearly sessile; var. *nivea*, Sims, fls. white. B.M. 1161. Gn. 78, p. 314. G.M. 57:191. The white-fl. plant cult. as *P. nivalis* and as *P. pubescens alba* is this form (see No. 20). In gardens are forms known as vars. *ciliata*, *coccinea*, and *Balfouriana*.

EE. Fls. short-pedicelled (pedicels usually $\frac{1}{4}$ in. or shorter):
scape equaling or exceeding the lvs.

F. Shape of lvs. narrow and cuneate.

42. *œnensis*, Thomas (*P. daonensis*, Leyb. *P. cadinensis*, Porta). Lvs. very viscid and bearing large red glands; oblong-cuneate to lanceolate-cuneate, grad-

44. *villôsa*, Jacq. Lvs. strongly viscid and densely covered with red glands, broad-obovate or oblong or oblong-lanceolate, gradually rarely suddenly narrowed to the petiole, obtuse, often dentate from the middle or only at the apex or even more or less subentire. scape red-glandular, about 6 in. high, exceeding the lvs., 1-12-fl.: bracts green or scarious, broadly ovate, obtuse: fls. rose or lilac; calyx glandular, not split to the middle with short triangular acute or obtuse lobes; corolla-tube slightly broadened toward the white throat, the limb $\frac{1}{2}$ -1 in. across with emarginate obcordate lobes. E. Alps. Gn. 61, p. 429. G.W. 6, p. 112. R.H.S. 39:105. Var. *commutata*, Chitt. (*P. commutata*, Schott. *P. villôsa*, subsp. *commutata*, Widm.), from Steiermark, has larger and thinner often oblong and coarsely toothed lvs. Gn. 61, p. 328.

3176. *Primula sinensis*. A young plant, as the flowers are beginning to appear. ($\times \frac{1}{2}$) No. 60.

ually narrowed to a petiole, obtuse or truncate at apex, upper margin serrate or dentate: scape mostly exceeding the lvs., about 3 in. high, with 1-7 fls.: bracts broadly ovate, scarious: fls. rose-colored; calyx densely glandulose, tubular-campanulate, with ovate obtuse lobes; corolla white in throat, the limb $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with emarginate obcordate lobes: caps. about equaling the calyx. Rhætian Alps. R.H.S. 39:105.—Said to be easily raised in partial shade in a variety of soils.

FF. Shape of lvs. oblong to broad-ovate.

43. *apennina*, Widm. Lvs. bearing large, short, yellow at length brown glands, ovate, oblong or lanceolate-cuneate, gradually or suddenly narrowed to the petiole, obtuse, entire or toward the apex slightly denticulate or dentate: scape slightly exceeding to double the length of the lvs., bearing 1-8 fls.: bracts scarious, ovate or rounded: fls. reddish purple; calyx glandular: caps. included in the calyx. Apennines.—Dwarf, blooming freely in April and May, in a shady part of rock-garden; said to prefer limestone soil.

45. *Cöttia*, Widm. Lvs. viscid and very densely covered with red glands, obovate or oblong-lanceolate, gradually or rarely suddenly narrowed to the short petiole, obtuse or subacute, denticulate or dentate from the middle, rarely from the base or rarely entire: scape frequently exceeding the lvs., glandular, bearing 2-12 fls.: bracts subscarious, obtuse: fls. rose; calyx glandular, campanulate with triangular obtuse or subobtuse lobes; corolla-tube scarcely broadened toward the glandular white throat, the limb $\frac{3}{4}$ -1 $\frac{1}{4}$ in. across with emarginate obcordate lobes: caps. about equaling or slightly shorter than the calyx. Cottian Alps, 3,200-8,000 ft. altitude. R.H. S. 39:105.

cc. Foliage farinose or not, sometimes glutinous but not red-glandular.

D. Bracts elongated: lvs. coriaceous, truncate at apex.

46. *minima*, Linn. Lvs. little more than $\frac{1}{2}$ in. long, shiny, firm, almost glabrous, the margin not cartilaginous, cuneate or obtriangular, exceedingly truncate and serrate at the apex, narrowed toward the base:

scape short or very short, shorter or rarely longer than the lvs., 1-2-fld.: bracts 1-2, small; fls. rose or white, when rose-colored usually bearing a white eye; calyx covered with sessile glands, not split to the middle, with obtuse or mucronate lobes; corolla-tube whitish, the throat glandular, limb funnel-shape from the base, finally flat, $\frac{1}{2}$ - $1\frac{1}{4}$ in. across, with bifid, obcordate lobes; caps. included in the calyx. Mountains of S. E. Eu. (Austria and Balkan region), in limestone and granitic regions. Gn. 61, p. 397. G.W. 15, p. 273. R.H.S. 39:113.—A choice little plant of several forms, one of which has fringed corolla-lobes. Plant about 1 in. high.

DD. *Bracts elongated: lvs. fleshy.*

E. *Scape equaling or exceeding the lvs.*

47. *Kitaibeliäna*, Schott. Lvs. more or less glandular-pilose, viscid, the glands discolored, subglaucous, intense-smelling, elliptic or oblong-lanceolate, gradually narrowed to the long petiole, acute or obtuse, margin entire or toward the apex wavy-denticulate: scape glandular, shorter than the lvs., bearing 1-2 fls.: bracts herbaceous, linear: fls. rose or lilac, with white throat; calyx glandular, reddish, split almost to the middle, with ovate or oblong, acute or obtuse lobes; corolla-tube white, the limb almost flat, $\frac{3}{4}$ -1 in. across, the throat glandular with emarginate, obcordate lobes; caps. included in the calyx. Mountains of S. E. Eu.—Needs a moist shady place.

48. *integrifolia*, Linn. Lvs. scarcely vicidulous ciliate, upper surface covered with few, small, pellucid glands, green, rather shining, margin not cartilaginous, very entire, elliptic or oblong, almost sessile, obtuse or subacute: scape glandular, reddish, bearing 1-3 fls.: bracts herbaceous, often reddish, linear or lanceolate, obtuse or acute: fls. rose-lilac, rarely white; calyx more or less reddish, glandular, not split to the middle, tubular or tubular-campanulate, with ovate or oblong obtuse lobes; corolla-tube broadened toward the densely glandular, rose-colored throat, the limb broad-funnel-form, $\frac{3}{4}$ -1 in. across, with emarginate lobes; caps. included in the calyx. Pyrenees and Alps. G.C. III. 52:253. R.H.S. 39:112.

EE. *Scape very short, less than the lvs.*

49. *tyrolensis*, Schott. Lvs. viscid, densely covered with hyaline glands, intense green, somewhat shiny, slightly scented, rounded or broad-obovate, suddenly narrowed to the very short petiole, apex rounded, minutely denticulate or almost subentire: scape glandular, more or less exceeding the lvs., bearing 1-2 fls.: bracts herbaceous, linear or lanceolate: fls. rose or rose-lilac; calyx glandular, split to the middle, campanulate, with ovate obtuse lobes; corolla-tube broadened at the glandular white throat, the limb broad-funnel-form, $\frac{1}{2}$ -1 in. across, with emarginate, obcordate lobes; caps. included in the calyx. Mountains of S. Cent. Eu. (Dolomites). R.H.S. 39:112.

50. *Alliönni*, Loisel. Lvs. strongly viscid, densely clothed with discolored glands, rather thick, gray-green, slightly scented, not cartilaginous margined, rounded or oblong or oblong-cuneate, gradually narrowed to the shorter or longer petiole, obtuse, entire, or denticulate: scape almost none, bearing 1-7 fls.: bracts scarious, ovate obtuse: fls. rose; calyx glandular, split to the middle with ovate obtuse or acute lobes; corolla-tube paler pink than the limb, the throat glandular, white or yellowish white, the limb $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with the lobes emarginate: caps. included in or equal to the calyx. Maritime Alps, both in sun "and in shallow sunless caves where neither sun nor rain reaches it." G.C. III. 53:85. R.H.S. 39:112.—Said to be difficult to grow in the open, but thrives in perpendicular position in rock-garden where well protected from sun and rain; may also be grown in a pot plunged in a frame.

DDD. *Bracts broad but short: fls. violet or rose.*

51. *marginata*, Curt. Plant 3-4 in. high: lvs. farinose, not cartilaginous margined, the surface not farinose, punctate with short glands, oblong or obovate, obtuse, narrowed gradually to a short petiole, regularly dentate-serrate: scape usually exceeding the lvs., bearing 2-20 fls.: bracts with the pedicels farinose, broad-ovate, lf.-like, short; fls. blue-lilac; calyx more or less farinose, campanulate, purplish, split almost to the middle, with the lobes triangular; corolla-tube many times exceeding the calyx, gradually broadened upward, the limb broad-funnel-form, rarely flat, $\frac{3}{4}$ -1 in. across, with emarginate lobes; caps. equaling or exceeding the calyx. Maritime and Cottian Alps. B.M. 191. Gn. 61, p. 398; 63, p. 261; 71, p. 179. G.W. 15, p. 271. R.H.S. 39:104.—Should not be grown vertically. Naturally it hangs from crevices in the rocks; it is recommended to grow it in an elevated place in the rock-garden where it may droop.

52. *carniolica*, Jacq. Entirely devoid of farina: lvs. glabrous or only the margin sparsely glandular-pilose, shiny, bright green, margin cartilaginous, obovate or oblong, narrowed to a short or long petiole, obtuse or subacute, entire or slightly wavy, very rarely remotely somewhat denticulate: scape much exceeding the lvs., sometimes 8 in. long, bearing a many-fld. umbel: bracts broad-ovate, obtuse or acute: fls. rose, at length lilac, white-eyed; calyx split to the middle, campanulate with acute or subobtusate lobes; corolla-tube gradually broadened to a farinose throat, the limb $\frac{1}{2}$ -1 in. across, broad-funnel-form with emarginate, obcordate lobes; caps. equaling or frequently exceeding the calyx. Alps, Idrian district, Austria, near Trieste. Gn. 61, p. 327. R.H.S. 39:104.—The plant is recommended to "be grown in turf to which has been added a little leaf-mold, in positions where it does not get full sun."

53. *viscosa*, All. (*P. latifolia*, Lapeyr.). Not farinose: lvs. fairly densely clothed with short discolored glands, intensely rank-smelling, yellowish green, rather soft, often more or less curved, the margin not at all cartilaginous, oval or oblong-cuneate or lanceolate-cuneate, obtuse or acute, gradually narrowed or contracted to a petiole more or less equaling the blade, dentate, wavy-dentate or entire: scape glandular, exceeding the lvs., bearing a several- to many-fld. umbel: bracts broad-ovate: fls. 1-sided, nodding, fragrant, violet or red-violet; calyx glandular, or even sparingly farinose, narrowly campanulate, split to the middle with the lobes acute or subacute; corolla-tube gradually broadened from the cylindrical base, the throat sparingly farinose, the limb funnel-form almost $\frac{1}{2}$ in. across with emarginate lobes; caps. more or less exceeding the calyx. Mountains of S. Eu., in several forms. Gn. 61, p. 430; 69, p. 186; 73: 572. G.W. 15, p. 272. H.F. 1:242. R.H.S. 39:104. Forma *cynoglossifolia*, Widm., has lvs. smaller and oval or oblong, entire or only lightly toothed: umbel many-fld. R.H.S. 39:104.—The *P. viscosa* of commerce, according to MacWatt, is chiefly varieties of *P. hirsuta*.

DDDD. *Bracts broad and leafy: fls. bluish violet*

54. *glutinosa*, Wulf. Deciduous: 3-4 in.: lvs. glandular-viscid, rather stiff, somewhat shining, punctate above, the margin toward the apex subcartilaginous, lanceolate-cuneate or oblong-lanceolate, gradually narrowed to the short-petiole, obtuse, denticulate from the middle, rarely subentire: scape exceeding the lvs., bearing a little head of 1-6 fls.: bracts broad, imbricate, frequently brownish purple, broadly ovate, obtuse: fls. fragrant, intense blue finally violet, rarely white; calyx glandular, not split to the middle, with ovate obtuse lobes; corolla-limb $\frac{1}{2}$ - $\frac{3}{4}$ in. across, funnel-form, with divaricate bifid lobes; caps. slightly shorter than the calyx. Tyrolean and Cent. Alps. Gn. 61, p. 359.—

Said to be difficult to flower under cult., but blooms freely in marshy places where it grows wild; it has the color of a blue gentian.

55. *deodrum*, Velen. Plant 8-10 in. high: lvs. provided with sessile glands, subcoriaceous, stiff, margin cartilaginous, punctate above, oblong or lanceolate, very entire, acute, gradually or scarcely narrowed toward the base: scape viscid, obscurely colored

3177. Single and semi-double flowers of *Primula sinensis*. (X1)

upward, exceeding the lvs., bearing a somewhat nodding, 1-sided umbel of 5-10 fls.: bracts oblong-linear: fls. intense purple-violet; calyx viscid, dark green, split to the middle, with narrowly triangular acute lobes; corolla gradually broadened toward the glandular throat, the limb funnelform, about $\frac{1}{2}$ in. across, with slightly emarginate lobes: caps. included. Bulgaria. B.M. 8124. G.C. III. 37:98. R.H.S. 39:113. F.S.R. 2, p. 239.—Said to be difficult to grow, but thrives in a rock-garden if well drained.

III. FLORIBUNDA.

Thin-lvd. verticillate species, with leafy involucrel bracts, from S. W. Asia and Afr.

A. Plant not farinose: calyx very deeply cut.

56. *floribunda*, Wall. BUTTERCUP PRIMROSE. Plant glandular-pubescent, 5-8 in.: lvs. elliptic or ovate, acute or obtuse, membranaceous, narrowed to a broad petiole which is shorter than the blade, irregularly dentate: scape bearing 3-5 many-fld., superimposed umbels which are distant from each other: bracts sessile, lf.-like, ovate or lanceolate, acute, denticulate: fls. golden yellow, fragrant; calyx split below the middle, broadly campanulate with acute lobes which are reflexed after flowering; corolla-tube slender with obcordate, rounded or slightly emarginate lobes: caps. ovate, smooth. Himalayas. B.M. 6712. G.C. II. 19:113; III. 27:195. Gn. 41:580; 61, p. 270. R.H. 1895, pp. 400, 401. Gt. 45:1424; 47, p. 221. Gn.W. 5:453. Var. *grandiflora*, Hort., is offered. Var. *Isabellina*, Hort., free-flowering, with sulfur-yellow bloom.—*P. floribunda* makes a good pot-plant for winter bloom, smaller and more compact than *P. kewensis*. It is grown the same as *P. kewensis* and *P. obconica*.

AA. Plant often farinose: calyx not cut to base.

57. *verticillata*, Forsk. Not glandular, very glabrous, scarcely farinose, 8-10 in. high: lvs. membranaceous, lanceolate or ovate-lanceolate, not farinose, acute or acuminate, irregularly and acutely serrulate, narrowed to a short broad-winged petiole: scape bearing several many-fld. superimposed umbels, farinose below the umbels: bracts 1-nerved; the lower lanceolate or lanceolate-linear, acuminate, sharp-serrulate, longer than the pedicels; the upper smaller, narrow, entire, shorter than the pedicels: fls. yellow, fragrant; calyx deeply parted, campanulate, with linear entire lobes; corolla glabrous, the tube slender, cylindrical, the limb $\frac{3}{4}$ in. across, with obcordate, slightly emarginate lobes: caps. globose, glabrous. S. Arabia. Gn.W. 24:398.—

Tender in England except in sheltered places in the milder parts; requires partial shade and a light soil.

58. *simensis*, Hochst. (*P. verticillata* var. *simensis*, Hook. f. *P. Courtii*, Hort. Veitch). Not glandular, bald, or farinose: lvs. membranaceous, ovate-elliptic, acute, irregularly and sharply serrate, narrowed to a short broad-winged petiole: scape bearing several many-fld. superimposed umbels: bracts 1-3-nerved; the inferior lanceolate or ovate, acuminate, sharp-serrate, longer than the pedicels; the upper smaller, subentire, shorter than the pedicels: fls. yellow; calyx deeply parted, campanulate, with triangular-lanceolate, entire lobes; corolla-tube slender, cylindrical; the limb about 1 in. across with broad-ovate, slightly emarginate lobes: caps. globose, included. Abyssinia. B.M. 6042.

59. *Boveana*, Decne. (*P. verticillata* var. *Boveana*, Mast.). Not glandular, more or less farinose or glabrous: lvs. membranaceous, rhomboid or spatulate, acute or acuminate, irregularly serrate or even somewhat incise-lobed, narrowed to a winged petiole which is shorter than the blade: scape bearing several many-fld. superimposed umbels: bracts (at least the lower) sessile, lf.-like, 3-nerved, rhombic-ovate, acuminate, sharp-serrate, exceeding the pedicels; the upper smaller: fls. yellow; calyx campanulate with triangular-lanceolate, acuminate, denticulate lobes; corolla glabrous, tube slender, cylindrical, the limb more or less than $\frac{1}{2}$ in. across with broad-ovate scarcely emarginate lobes: caps. globose. Sinai. B.M. 2842 (as *P. verticillata*).

IV. SINENSES.

Plants of various habit, with lobed distinctly petiolate lvs., the lobes dentate or crenate. Himalaya-Chinese region.

A. Calyx prominently inflated, truncate, or squared at the base.

60. *sinensis*, Lindl. (*P. chinensis*, Hort. *P. Mandarina*, Hoffmg. *P. prænans*, Ker. *P. semperflorens*, Lois.). CHINESE PRIMROSE. Figs. 3176, 3177. Trunk short and woody, but as known in gardens the plant is practically stemless, the ample foliage and the strong short scapes arising directly from the surface of the ground or very near it: whole plant soft-hairy: lvs. rotundate, soft, and usually limp, several-lobed and

3178. Wild form of *Primula sinensis*, after one year's cultivation from seed collected in China.

the lobes unequally incise-dentate, long-petioled: scapes erect, exceeding the lvs., bearing 2-3 superimposed umbels: fls. now of many colors, several to many in an umbel, large and showy, salverform, the segms. obcordate; calyx inflated; corolla-limb about $1\frac{1}{4}$ in. across, spread out, the lobes broad-cordate, emarginate: caps. glabrous. China. Winter bloomer, as grown in

3179. Wild form of *Primula sinensis*, as it grows at Ichang, China.

greenhouses. B.M. 2564. L.B.C. 10:916, 20:1926. B.R. 539. F.S. 22:2334-7. I.H. 32:551; 35:42. Gn. 51:468 and p. 469. G.C. III. 25:181, 203, 205. Gng. 2:91. A.F. 8:623, 625, 671. F.R. 4:29.—The Chinese primrose is variable under cult. There are double-fl'd. forms of various shapes and colors and of various degrees of doubling. For pictures of various double and half-double forms, see R.H. 1867:250, 330. F.S. 20:2145. I.H. 31:512; 35:42; 38:126. J.H. III. 44:515. The normal form of this primrose has a somewhat flat-topped fl.-cluster, but there are forms with pyramidal and elongated clusters. *Primula sinensis* was intro. into England from Chinese gardens in 1820, but it was not until 1879 that the original wild form was known to botanists. For accounts and pictures of this wild primrose as grown in English gardens, see essay by Sutton in Journ. Royal Hort. Soc. 13:99 (1891). G.C. III. 5:117; 8:564; 9:209; 31:270 (reproduced, less than half in Fig. 3179); 11:13 and 31:271 showing the plant after one year of cult. and reduced in Fig. 3178 (figure reproduced in A.G. 13:245). Gn. 49:214. B.M. 7559. G.C. III. 45:148; 55:131. Gn. 62, p. 307. R.H.S. 39:128. Dr. Augustine Henry, who has collected the wild plant at Ichang, in China, writes in Gardeners' Chronicle that "The habitat and mode of growth is remarkably different from what we find in the cultivated forms. The wild plant grows on the ledges of rocky cliffs of limestone, in spots where there is no soil, and practically no moisture, exposed to the sun, and living amidst the decaying remains of former generations of the plants. These ledges of *Primula* are often continuous for hundreds of feet, and in December and January, when the flowers appear, present a scene of great beauty. The scent of the leaves is very strong, and can be perceived at once on entering any of the ravines where the ledges occur. The flowers are pinkish, with a yellow ring around the neck of the corolla."

The general improvement of *P. sinensis* has taken place without hybridity with other species. There are now crested or fringed forms (var. *fimbriata*, Hort.), and those with a frill or extra corolla projecting from the throat (Fig. 3177). Gt. 43:1402; 45:1432; 46, p. 192. G.Z. 31:217. H.F. II. 2:228. G.C. III. 27:141. J.H. III. 62:31. The lvs. are variable in shape and depth of lobing. Some forms have crisped lvs. (var. *filicifolia*, Hort.). G.Z. 12:2. Var. *stellata*, Hort. (*P. stellata*, Hort.), Fig. 3180, is a form with handsome star-like long-stemmed fls. in successive whorls or tiers in a long open cluster, in pink, blue, red, and white; now a popular conservatory and florist's form, prized for its taller and freer habit and smaller more numerous fls. Gn. 53, p. 229; 57, p. 52; 59, p. 252 (bench). G. 20:632; 26:88. G.C. III. 45:149. R.B. 36, p. 268. Gt. 64, p. 91. A.F. 17:7; 18:42. F.E. 19:339. A.G. 18:201; 20:384, 385. A.F. 12:605. Gng. 5:167.

AA. Calyx produced into a horn.

61. *pycnoloba*, Bur. & Franch. Plant woolly: lvs. petioled, broadly ovate-cordate, the apex subobtusely lobulate, the lobes unequally denticulate: scape shorter or longer than the lvs., bearing 5-12 fls.: bracts large, lanceolate, reticulate-nerved: corolla-tube cylindrical, the lobes small, erect, obovate emarginate and apparently subincised. Cent. China. Intro. 1906. B.M. 8612. R.H.S. 39:148.—Of this plant Balfour writes: "From a group of petiolate hairy leaves with broad heart-shaped lamina, so common in plants of its alliance, there arises a short scape bearing a close cluster of flowers in which the calyx has enlarged as a long creamy white membranous horn with wide mouth, from the edge of which extend the spike-like sepaline segments. Closing, as it were, the mouth of the horn is seen the small dark red limb of the corolla. There is nothing like it elsewhere in *Primula*. The species is easily grown if protected from overhead moisture when resting, and it spreads rapidly in the soil by root buds which provide a ready means of propagation." He makes for it the Section *Pycnoloba*.

AAA. Calyx little or not at all inflated, narrowed at the base.

B. Shape of calyx goblet-like, after flowering becoming larger.

c. Lobes of calyx entire, acute.

62. *Siëboldii*, Morr. (*P. cortusoides* var. *amëna*, Lindl., var. *grandiflora*, Lem., and var. *Siëboldii*, Hort. *P. patens*, Turcz. *P. amëna*, Hort.). Fig. 3181. Pubescent all over except the corolla: lvs. petioled, ovate-oblong, base cordate, lobed, the lobes numerous, unequally dentate; the petiole longer than the blade: scape exceeding the lvs., bearing a simple many-fl'd. umbel: fls. white, rose, or purple; calyx funnelform, with narrowly triangular-lanceolate acute lobes which are lf.-like and glabrous; corolla-lobes broad and emarginate. Japan. B.M. 5528. I.H. 16:599. Gn. 29, p. 382; 35, p. 335; 36:318; 72, p. 327. G.M. 51:911. G. 9:454; 19:175. G.L. 17:365. C.L.A. 23, No. 5, 53. R.H.S. 39:176. Gng. 8:241, 242. R.H. 1892:300.—Looks like a large and robust form of *P. cortusoides*, with fls. $1\frac{1}{2}$ to nearly 2 in. across, the throat usually striped and the limb in various colors. The fls. are two to three times larger than those of *P. cortusoides*. In some forms the fls. are fringed. Blooms in late spring. Hardy N. Several named forms are mentioned in gardening literature, as var. *clarkiflora* (G. 37:109), var. *grandiflora*, and others.

63. *obcónica*, Hance (*P. poculiformis*, Hook.). Fig. 3182, and Plate XCII. Slender, with loose-hairy lvs. (the sharp hairs often irritating-poisonous): lvs. all radical, ovate-oblong or round-oblong, base more or less cordate, long-petioled, scallop-toothed and very finely serrate: scapes many, 4-10 in. tall, exceeding the lvs.: bracts small, linear, and unequal: fls. small, lilac or light purple, several to many in umbels, on long-spread-

ing or somewhat drooping pedicels, the segms. obcordate; calyx wide open and shallow-toothed. China. B.M. 6582. Gn. 26:206 and p. 206; 29, p. 241; 51, p. 317; 60, p. 416; 61, p. 271; 72, pp. 190, 255; 77, p. 630. G.C. III. 9:401 (house); 35:245; 40:208; 47:28. G.M. 44:51. Gn.M. 2:228. G. 7:389; 20:33; 28:128, 129; 32:321. C.L.A. 2:233. R.H.S. 39:144. Gt. 43, p. 138. F.R. 1:941.—Of late years this species has become a popular winter-blooming pot-plant. The fls. are nearly or quite an inch across in well-grown specimens. There is a var. *grandiflora*, Hort., with fls. nearly or quite $1\frac{1}{2}$ in. across. Gn. 51:316; 74, p. 200. J.H. III. 60:196. G.W. 3, p. 109. R.H. 1892, p. 114. Gt. 46, p. 193. S.H. 2, p. 52. A.F. 13:1063; 18:43. Gng. 6:245. Some of the large-fl. forms have somewhat lacerated or fringed petals (var. *fimbriata*, Hort.); var. *rosea*, Hort., has rose-colored fls.; var. *semi-plena*, Hort., has partially doubled fls. (G.M. 46:206); var. *superba*, Hort., is a large-fl. race in different colors. (R.H. 1906:448); var. *undulata*, Hort., has crisped or undulate fls. (R.H. 1914:300).—Intro. 1880. For history, see Hill, Journ. Genetics, Vol. 2 (1912). *P. obconica* is very easily grown. Prop. by seed. Persons liable to poisoning by the hairs of *P. obconica* should rinse the hands or exposed parts in alcohol, then wash with soap and water.

A number of very recent species closely allied to *P. obconica* are likely to find their way into cult. and perhaps to extend the usefulness and range of this type of primula. Some of these species are: *P. ambita*, Balf. f., a glabrous type from a dry site, with a remarkable involucre; *P. barbicalyx*, C. H. Wright, hairy all over and with a bearded calyx, the lvs. somewhat elongated and with rounded lobes; *P. oreodora*, Franch., in which the characters of *P. barbicalyx* are more emphasized (the plant cult. under this name is said to be *P. saxatilis*); *P. begoniæformis*, Petitm., smaller than *P. obconica* and less hairy; *P. parva*, Balf. f., very dwarf, xeromorphous; *P. Vilmoriniana*, Petitm., very hairy, lvs. 2-3 times usual size, scapes short, fls. minute; *P. Petitmenginii*, Bonati, a grotto plant, lvs. large, membranous, and delicate, scapes very short.

64. *sinolisteri*, Balf. f. A recent species of the *P. obconica* type that promises to be of much horticultural value, since it does not have the irritant hairs, is a free grower, forms compact masses of foliage, and produces many trusses of white sometimes lilac fls.: lvs. acutely lobed. Yunnan, China. R.H.S. 39:145.—Said to have been distributed as *P. Listeri*.

cc. Lobes of calyx entire, obtuse.

65. *Listeri*, King (*P. obconica* vars. *rotundifolia* and *glabrescens*, Franch.). Lvs. petioled, glabrescent or glabrous, membranaceous, opaque, reniform-orbicular from a cordate base, sinuate-dentate, the lobes irregularly few-toothed or subentire, acute; the petioles slender, manifestly longer than the blade, very short-pubescent, glabrescent; scape much shorter than the lvs., glabrescent, 3-5-fl. bracts small, linear; fls. rose; calyx almost glabrous, broad-campanulate, with broad-semiorbicular, obtuse or scarcely mucronulate lobes; corolla-tube almost $\frac{1}{2}$ in. long, the lobes obovate, bilobed, at other times entire or denticulate. Himalayas; usually credited to China, but the oriental forms are probably distinct. G.C. III. 53:271.

ccc. Lobes of calyx denticulate.

66. *malvacea*, Franch. (*P. langkongensis*, Forr.). Whole plant fairly densely short-pubescent; lvs. glabrescent, bright green, open-cordate at the base, rotundate or very broadly ovate, coarsely crenate, the crenatures denticulate; the petioles longer than the blades; scape thick, exceeding the lvs., bearing 2-3 superposed umbels which are slightly separated from each other; bracts, those below the lowest umbel, fl.-like, large, ovate-lanceolate; fls. reddish; calyx pubes-

cent, at the same time clothed with melliferous glands intermixed, cup-shaped, with the lobes frequently denticulate; corolla-limb about $\frac{3}{4}$ in. across, distinctly annulate at the throat, with obovate, 2-lobed lobes; caps. small, globose, not exceeding the calyx-tube. China. Intro. 1908. R.H.S. 39:149.

67. *blattariformis*, Franch. Whole plant covered with short papilliform hairs: lvs. ovate or obovate, from a rotund or shortly attenuate base, coarsely crenate, the crenatures denticulate; the petioles shorter than the blades; scape erect, much exceeding the lvs., bearing a raceme 8-12 in. long; the pedicels short; bracts equaling the calyx; fls. lilac; calyx broad-campanulate, with acute dentate lobes; corolla-tube puberulent outside, the limb $\frac{1}{2}$ - $\frac{3}{4}$ in. across, broadly obcordate, acute; caps. subglobose, small, included in the calyx. China. —"A first glance at the plant suggests *Verbascum*."—Balfour.

BB. Shape of calyx more or less tubular, little if any enlarging after flowering (perhaps exception in No. 80).

c. Stamens affixed in base of corolla-tube.

68. *heucherifolia*, Franch. (*P. Gagnepainii*, Petitm.). Lvs. petiolate, deeply and narrowly cordate, rotundate, 7-9-lobed to a depth of scarcely one-fourth the diam., sparsely pilose, the lobes ovate-deltoid, unequally dentate; the petiole villous with red hairs; scape much exceeding the lvs., when mature short-pulverulent as well as short-pilose, bearing 3-4 fls.: bracts short, linear-lanceolate, pulverulent; fls. purplish; calyx narrowly

3180. *Primula stellata* of florists, a form of *P. sinensis*, prized for its small well-formed slender-stalked flowers that stand well above the foliage. ($\times \frac{1}{2}$)

campanulate-tubular, with lanceolate acute lobes; corolla-tube cylindrical, the limb concave, about $\frac{1}{2}$ in. across, with shortly bilobed lobes. Thibet and China. G.C. III. 50:102.

cc. Stamens affixed in the tube or at the throat of corolla.

d. Lvs. paper-like, suborbicular, glaucous beneath.

69. *chartacea*, Franch. Lvs. long-petiolate, chartaceous, glabrous, ovate-suborbicular, base slightly cordate, obscurely crenate-dentate, glaucous above, pin-

nately somewhat 7-nerved, both surfaces densely finely rusty-punctate: scapes frequently several, 2-3-fld.; the pedicels very slender-puberulent: fls. rose-lilac; calyx urn-shaped, 5-cleft to the middle, the lobes oblong, obtuse, strewn especially at the margin with resinous red dots; corolla salver-shaped, the lobes ovate, 2-cleft: caps. spherical, not exceeding the calyx-tube. Cent. China.

DD. *Lvs. membranaceous or thin, oblong in general outline, doubly crenate and often somewhat lobed.*

70. *cortusoides*, Linn. Lvs. in a rosette on the ground, rather large and soft, loose-hairy (at least on the midrib and petioles), ovate-oblong or cordate-oblong, irregularly many-notched: scapes few to several, 6-12 in. tall, much exceeding the lvs., very straight, hairy: bracts linear: fls. rose-colored, about 1 in. across, short-pedicelled, in a loose many-fld. umbel, the segms. obovate and deeply notched or even lobed. W. Siberia. B.M. 399. Gn. 29, p. 382; 62, p. 217. G.M. 43:247.—A handsome hardy species, blooming in May in the northern states, and represented by garden forms; known sometimes as "bear's-ear primrose," from the large radical lvs. G. 2:207 (var. *amæna*); J.H. III. 44:277 (var. *grandiflora lilacina*). It is a question, however, whether *P. cortusoides* is now much known in cult., the plants grown under this name being perhaps *P. Sieboldii* and *P. saxatilis*. It is recognized, according to Balfour, by the short pedicels of the fls.

71. *saxatilis*, Komar. Fig. 3183. Plant pubescent: lvs. oblong or broadly oblong-ovate from a cordate or subcordate base, incise-frequently slightly curled-incise-lobed, the lobes sometimes subentire, sometimes crisped or dentate; the petioles frequently exceeding the blades: scape exceeding the lvs., pubescent below, subglabrous above, bearing 1-10 fls.: bracts linear: fls. rose-violet; calyx ovate-cylindrical or narrowly campanulate,

3181. *Primula Sieboldii*. ($\times \frac{1}{3}$)

prominently nerved, with deltoid acute very shortly puberulent lobes; corolla tubular, the limb up to $\frac{3}{4}$ in. across, with emarginate lobes: caps. oblong, included, very glabrous. E. Siberia. R.H.S. 39:173.—Said to be cult. under the name of *P. oreodoxa*. Pedicels much exceeding the bracte

DDD. *Lvs. membranaceous, rounded or deltoid in general outline, lobed.*

E. *Foliage bullate or blistered.*

72. *violodora*, Dunn. Plant pubescent: lvs. reniform or orbicular, frequently bullate, base cordate, lobed, the lobes bicrenate; the petiole longer than the blade, covered with violet hairs: scape 8-12 in. high, bearing 2-3 superposed umbels, rarely only 1: bracts small: fls. with the odor of violets, rose-lilac; calyx subglabrous, green, narrowed at the base, with very acute strongly nerved lobes; corolla-tube cylindrical, the mouth yellow, the limb up to $\frac{3}{4}$ in. across, with obcordate lobes. Cent. China.

EE. *Foliage not bullate or blistered.*

F. *Lobes of lvs. obtuse (the lobes sometimes with more or less acute large teeth).*

73. *möllis*, Nutt.

Plant softly hirsute-pubescent, 1 ft.: lvs. deeply cordate at the base, the sinus closed, cordate in general outline, sinuate-lobed, crenulate-denticulate, softly pubescent; the petiole densely pubescent, equaling or exceeding the blade: scape pubescent, 8-10 in., after flowering growing to as much as 16 in. high, much exceeding the lvs., bearing 3-5 many-fld. superposed umbels: bracts lanceolate, the upper narrower: fls. bright rose; calyx intense red, soft-hirsute, tube turbinate, with spreading acute lobes; corolla-limb more or less oblique, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with obovate emarginate lobes. E. Himalayas. B.M. 4798. F.S. 12:1230. Gn. 76, p. 424. G.W. 13, p. 123. R.H.S. 39:184.—May and June to July, requiring a moist or boggy place.

74. *sinomöllis*, Balf. f. Lvs. gray-hairy, rounded, petiolate, very shallowly rounded-lobed or scalloped: scapes long, bearing superposed whorls of red fls.: calyx cup-shaped to campanulate, ribbed, with straight erect lobes. Yunnan, China. Intro. 1913. R.H.S. 39:148.

75. *septemloba*, Franch. Whole plant scattered with soft white hairs: lvs. up to $3\frac{1}{2}$ in. diam., in outline orbicular, deeply cordate, sparsely pilose, 7-lobed, the lobes one-third the depth of the lf.-diam., broadly ovate or triangular, obtuse but sometimes with more or less acute large teeth, denticulate; the petioles somewhat hairy, much exceeding the blade: scape up to 12 in. high, slender, clothed with spreading hairs, bearing a small cluster of fls.: bracts linear-lanceolate, obtuse: fls. reddish purple, semi-pendulous and somewhat fragrant; calyx glabrous, tubular-campanulate with lanceolate acute lobes; corolla-limb about $\frac{1}{2}$ in. across, concave, with obovate emarginate lobes. Cent. China. Intro. 1908. G.C. III. 58:297. R.H.S. 39:145.

76. *oculata*, Duthie. Allied to *P. septemloba*, with geranium-like lvs. and red-purple drooping fls. which are darker in color than those of the related Chinese species. W. China. Intro. 1904.

FF. *Lobes of lvs. acute.*

77. *Kaufmanniana*, Regel. Lvs. pubescent, becoming glabrescent, petiolate, about 2 in. long and broad,

3182. *Primula obconica*. ($\times \frac{1}{2}$)

orbicular in outline, cordate or subtruncate at base, the many lobes oval and few-toothed, the petiole exceeding the blade: scape 6-8 in. tall, over-topping the lvs., soft-pubescent below and glabrescent above, carrying a many-fl. umbel: bracts lanceolate, acute, exceeding the pedicels: fls. rose-purple; calyx glabrous or nearly so, the lobes erect and acute; corolla exceeding calyx, the limb more than $\frac{1}{2}$ in. across, the obcordate lobes emarginate. Cent. Asia.

78. *polyneura*, Franch. Lvs. petiolate, 1-2 $\frac{1}{2}$ in. long, broadly deltoid or suborbicular, about 11-lobed, the lobes broadly ovate and dentate or crenate, the petiole very long: scape 4-16 in. tall, much overtopping the lvs., pubescent, the umbel solitary or 2 or 3 superposed: bracts lanceolate, shorter than the villose pedicels: fls. purplish or violet(?); calyx ribbed, long-tubular, pilose, the lobes lanceolate-acute; corolla-tube cylindrical, twice exceeding the calyx, the limb about $\frac{1}{2}$ in. across, lobes bifid. Cent. China.—*P. Veitchii* and *P. lichiangensis* may be minor forms of this.

79. *Veitchii*, Duthie. Lvs. petioled, when young subrugose, about as broad as long, lobed, the lobes dentate, green and pubescent above, dense-white floccose-tomentose beneath; the petiole equaling the blade: scape exceeding the lvs., 10-12 in. high, bearing a rather densely many-fl. umbel or several umbels superposed: bracts shorter than the pedicels, ciliate, pubescent: fls. rose-purple or violet, the anthers yellow; calyx subtruncate at the base, pubescent, with lanceolate acute often unequal lobes; corolla pubescent, the limb yellow-tinted at the mouth with broad-obcordate emarginate lobes: caps. twice as long as the calyx. Cent. China. Intro. 1906. B.M. 8051. G.C. III. 37:344. G.M. 48:314. R.B. 36, p. 270. R.H.S. 39:144.—A very desirable hardy free-flowering species. *P. Veitchiana*, Petitm., is a different species, apparently not in cult.

80. *lichiangensis*, Forr. (*P. cortusoides* var. *lichiangensis*, Forr.). Much like *P. Veitchii*, but foliage less hairy and not white underneath, and fls. fewer, larger, and more drooping, with larger eye and purple anthers, the calyx somewhat inflated at base: plant 6-14 in. tall: lvs. petiolate, ovate-oblong, deeply cordate, lobed, and toothed: bracts lanceolate: fls. fragrant, rich rose-red or almost crimson in shade, the eye greenish yellow. Lichiang Range, N. W. Yunnan, China, altitude 10,000 ft. Intro. 1908. G.C. III. 50:472. R.H. 1912, p. 488. G. 35:9. R.H.S. 39:129.

81. *geraniifolia*, Hook. f. Very short-pubescent: lvs. about 2 in. long and broad, orbicular in outline, cordate at base, 11-15-lobed, the lobes triangular and many-toothed and acute, the slender petiole much exceeding the blade: scape 8-10 in. high, bearing 1 or 2 umbels: bracts small (about $\frac{1}{2}$ in. long), linear: fls. rose-colored, on slender pedicels about $\frac{1}{2}$ in. long; calyx campanulate, glabrous, the lobes acute; corolla exceeding calyx, the limb about $\frac{1}{2}$ in. across, the lobes lightly emarginate. Thibet. R.H.S. 39:184.

82. *Paxiana*, Gilg. Plant tall and very showy: lvs. very thin-membranaceous, reniform from an open cordate base, acute, many-lobed, at first sparse-pilose on the nerves, somewhat ciliate, primary nerves 3, prominent, dividing ternately, the lobes shortly and broadly triangular, denticulate; the petiole much exceeding the blade: scape tall, 16-20 in. high, sparsely puberulent, bearing 3-4 superposed umbels which are 4-6-fl. and 1-2 in. apart: bracts small, almost subulate: fls. bluish lilac; calyx campanulate, somewhat strigose-puberulent with acute lobes; corolla cylindrical, the limb up to 1 in. across, with obovate, deeply bifid lobes. China.—The foregoing species may be difficult to separate from printed descriptions. In *P. Kaufmanniana* and *P. polyneura*, the lf.-lobes are oval and few-toothed; the former has a glabrous and the latter a pilose calyx. In *P. geraniifolia* and *P. Paxiana* the lobes are triangular

and many-serrate; in the former the corolla-tube is twice and in the latter thrice or more longer than the calyx.

V. MONOCARPICÆ.

Lvs. little if at all lobed: calyx leafy, often much enlarging after flowering: Chinese.

83. *malacoides*, Franch. FAIRY PRIMROSE. Fig. 3184. A slender and open grower, 8-20 in. high, larger and more branched than *P. Forbesii*, somewhat hairy below with white hairs, glabrous above: lvs. thin-papery, glabrescent, broad-ovate, under surface sometimes sparsely white-farinose, upper pale green, the base open-cordate, broadly 6-8-lobed, the lobes acutely incise-dentate; the petiole exceeding the blade: scape more or less exceeding the lvs., bearing 2-6 many-fl. superposed umbels which are distant from each other: bracts short, linear-lanceolate, acute, white-farinose below: fls. rose and lilac; calyx densely white-farinose, campanulate from a spherical base, with the lobes

3183. *Primula saxatilis*. Often cultivated under the name of *P. cortusoides*. (Separate fls. $\times \frac{1}{2}$)

short, acute, and spreading; corolla-tube cylindrical, slender, the limb a little concave, $\frac{3}{8}$ - $\frac{1}{2}$ in. across, with obcordate lobes: caps. globose, included. China. Intro. 1908. G.C. III. 44:396, 397; 52:308. R.H. 1912:156. Gn. 76, p. 157; 77, p. 291, 624. J.H. III. 60:399. G. 31:53. G.M. 51:914; 56:917. G.W. 13, p. 42. Var. *alba*, Hort., has white fls. Var. *plena*, Hort., has double fls. G.C. III. 54:428.—An excellent greenhouse species, blooming well in winter. Although perennial, it is usually treated as an annual; seed sown in spring should produce flowering plants in autumn. It blooms several months, bearing fls. in successive whorls on very slender sts., which sometimes reach a height of 18 in. It is now common in cult., and self-sows about the greenhouse. Several shades of color are represented, and also large-fl. forms which are possibly hybrids (see G.C. III. 55:180). The plant grows well out-of-doors in the

rock-garden in mild climates, with some protection. Often confounded with baby primrose (*P. Forbesii*), but the oblong long-petioled lvs. at once distinguish it, as well as the tall and open infl.

84. *pseudomalacoides*, Stewart. Much like *P. malacoides*, but more delicate in every way and said not to seed readily unless cross-pollinated: lvs. more prostrate, oblong. Yunnan, China. Intro. 1908.

85. *Fórbessii*, Franch. BABY PRIMROSE. Figs. 3185, 3186. Handsome slender species, monocarpic in the form first intro. but a perennial as now grown: loosely white-hairy, at least on the lvs. and lower part of the scape: lvs. small, 1-2 in. long, oval-oblong to cordate-oblong, shallowly sinuate-toothed, minutely serrulate: scapes very slender, 6-14 in. high, much exceeding the lvs., often bent above the whorls: fls. small (about $\frac{1}{2}$ in. across), light lilac, slender-pedicelled, appearing in successive umbels or whorls, the segms. obcordate, calyx sharp-toothed, small, somewhat loose. China; Burma, 3,000 ft. B.M. 7246. R.H. 1892, p. 259. G.C. III. 14:685; 35:20; 40:192. J.H. III. 49:287. R. H.S. 39:149. A.F. 14:757. Gng. 7:149. F.E. 11:72.—Although first described so recently as 1886, and first exhibited in London in 1891, this plant was once a common conservatory plant in America. It is a most profuse bloomer, beginning to flower when not more than 2 or 3 in. high and continuing until the scapes reach a height of 10-12 in. It is easily grown from seeds, and blooms well all winter. Unless given plenty of light and room, the scapes become weak and crooked. In recent years it has dropped from favor with florists, its place being taken in part by *P. malacoides*. Its botanical status is not well understood.

VI. MINUTISSIMÆ.

Plant very small or minute, producing stolons: lvs. toothed or crenate: Himalaya, Thibet.

86. *minutissima*, Jacq. Plant very small, stoloniferous, the stolons short and leafy: lvs. small, less than $\frac{1}{2}$ in. long, sessile, spatulate-obovate or lanceolate, acuminate, dentate or crenate, more or less farinose below: scape very short, almost hidden among the lvs., 1-3-flid.: bracts 1-2, small: fls. strictly sessile, large in relation to the plant's size, purple; calyx glabrous, tubular-campanulate, split to the middle with acute lobes; corolla-tube slender, the limb $\frac{1}{2}$ in. or less across, with obcordate, deeply emarginate lobes. Himalayas.

VII. OMPHALOGRAMMA.

Lvs. little if any lobed: fls. solitary on a bractless scape, the calyx little or not at all enlarging after flowering: China, Himalaya.

A. Fls. appearing with or after the lvs.

87. *vinciflora*, Franch. Plant with a short perennial rhizome: lvs. thin, papery, oblong or oval, densely overlapping and forming a narrow erect crown, all erect or nearly so, the upper ones larger, all entire but ciliate,

covered with reddish glands: scape short (6-9 in.): fl. solitary, purple-violet or blue, $1\frac{1}{2}$ in. across, the tube cylindrical or long-obconic, yellowish at the base and covered with black glandular hairs outside; the segms. well separated and broadly obcordate, the 3 upper reflexed on the tube; calyx small, not inflated. China. B.M. 8564. G.C. III. 1:574; 40:230; 54:198. Gn. 77, p. 497; 79, p. 242.—A most odd species, with vinca-like fls., of simple cultural requirements.

88. *Elwesiana*, King. Rhizome scaly: lvs. about 4 in. long, including the petiole, ovate-lanceolate, very remotely and scarcely denticulate, almost subentire, leathery, acute, glabrous, gradually narrowed to a winged, puberulent petiole: scape stout, 4-6 in. high, without bracts, red-hairy, 1-flid.: fls. violet; calyx pubescent, parted almost to the base, with lanceolate-linear, subobtuse lobes; corolla-tube pilose, broadened toward the throat, the limb funnelform, with almost quadrate lobes which are slightly narrowed toward their base and are almost truncate and denticulate at their apex: caps. cylindrical, equaling the calyx. Sikkim, Himalaya.

AA. Fls. appearing before the lvs.

89. *Delavayi*, Franch. Plant slightly soft white-hairy pubescent: lvs. long-petiolate, thin-papery, about 3 in. long and almost as broad, broadly ovate or suborbicular, the base more or less cordate, wavy-dentate or crenate: scape produced before the lvs., without bracts, 1-flid., densely pubescent, laxly enveloped up to the middle with fuscous, membranaceous, very broad scales: fls. bright purple; calyx broadly campanulate, deeply parted, with linear-lanceolate lobes about $\frac{1}{2}$ in. long which are entire or denticulate and acute or obtuse; corolla outside pilose, the funnel form tube broad, slightly constricted above the base, then gradually broadened, the throat sprinkled with hairs, with oblong-ovate incised lobes: caps. ovate-oblong, $\frac{3}{4}$ -1 in. long, $\frac{3}{4}$ in. thick. S.W. China.

VIII. BULLATÆ.

Lvs. strongly rugose or bullate, hairy or glandular, more or less coriaceous, little

if any lobed, small (2-4 in. long): fls. pedicelled: China, Thibet.

90. *ovalifolia*, Franch. Lvs. membranaceous, finally subcoriaceous, ovate, obtuse, crenulate or subentire, ciliate, contracted abruptly to the petiole which equals or is shorter than the blade and is more or less covered with red hairs: scape 1-6 in. high, equaling or shorter than the lvs., somewhat red-hairy: bracts lanceolate, acuminate: fls. purple; calyx open-campanulate, with lanceolate acuminate, hairy lobes; corolla-tube broadened to the concave limb, which is up to 1 in. across, with obovate slightly emarginate lobes. Cent. China. Intro. 1906. G.C. III. 38:70.

91. *Fórestii*, Balf. f. Beautiful undershrub of very recent intro., not farinose, with glandular fragrant foliage, and in its native places producing rootstocks 2-3 ft. long and probably in some cases 50-100 years old: lvs. petiolate, ovate-elliptic, attenuate or sub-

3184. *Primula malacoides*. ($\times \frac{1}{2}$)

cordate at base, irregularly bi-crenate, rugose above and densely farinose beneath: scape stout and erect, 3-9 in. high and equaling or exceeding the lvs., bearing a 10-25-fld. umbel: bracts leafy, lanceolate: fls. on slender erect pedicels, large, fragrant, deep orange (or deep yellow?) with an orange-yellow tube; corolla-limb nearly 1 in. across, the lobes ovate or rounded and deeply emarginate; calyx pouch-like or scarcely campanulate: caps. ovoid. Pendulous from dry shady crevices of limestone cliffs of the Lichiang Range, S. W. China; in cult. said to thrive in limestone well-drained soil in the alpine rocky. Intro. 1908. B.M. 8313. G.C. III. 45:274, 299; 51:240. R.H.1912, p. 490. Gn. 73, p. 242. G.M. 52:325. G. 31:289; 36:209. R.H.S. 39:152.—Placed in a new section *Suffruticosa* by Balfour, together with several others. A very recent and interesting species of this group is *P. rufa*, Balf., with golden meal and hairy: fls. yellow. Yunnan, China.

92. *rédolens*, Balf. f. Allied to *P. Forrestii* and in foliage much resembling it but softer and more hairy: scapes 6-9 in. tall, bearing umbels of 12-20 fls. that vary in color from white to pale pink and splashed purple, with a small yellow eye. W. China; a very recent intro., and probably not yet tested in this country.

93. *cærulea*, Forr. Rhizome not woody: lvs. petiolate, 2-4 in. long, ovate or ovate-elliptic, densely pubescent beneath and mostly bullate (puckered) above, at the base more or less attenuate, at the apex rounded, sinuate-crenate: scape 1-3 in. high, more or less woolly, 1- or 2-fld.: calyx broadly bell-shaped, lightly pubescent, the lobes triangular and acute; corolla purplish blue, the tube funnellform and throat greenish yellow, the limb 1 in. or more across, lobes broadly obovate and entire or nearly so. China, on rocks in exposed situations. Intro. 1911.

IX. CAROLINELLA.

Much like *Bullata*, but lvs. larger: Asia Minor, China.

94. *megaseæfolia*, Boiss. More or less somewhat ferrugineously-pilose, at length almost glabrous everywhere: lvs. chartaceous, rotund or ovate-rotund, obtuse, the base slightly cordate or subrotund, remotely somewhat spinulose-dentate, glabrous above, ferrugineous-pubescent along the nerves below; the petioles stout, more or less equaling the blade, narrowly winged: scape shorter than or equaling the lvs., glabrescent, bearing 1 or 2 closely approximate superposed many-fld. umbels: bracts lanceolate, with a subulate-acuminate apex; pedicels slender, nodding white infl.: fls. rose; calyx glabrous, narrowly tubular, 5-ribbed, with lanceolate, acute, slightly reflexed lobes; corolla-limb 1 in. across, with obcordate, deeply emarginate lobes: caps. glabrous, oblong, exceeding the calyx. Mountains of Asia Minor, B.M. 7901. G.C. III. 29:223. Gn. 59, p. 298; 65, p. 323. G.M. 44:287. G. 32:347. Gn.W. 20:211. F.S.R. 2:24. R.H.S. 39:117.—An interesting and distinct species, suitable for outdoor planting.

X. FALLACES.

Lvs. membranaceous, rugose, hairy, cordate at base, distinctly petiolate: infl. bracteate, about 2-3-fld. Japan.

95. *Reinii*, Franch. Densely covered with long, many-celled hairs, especially the petioles and the upper surfaces of the lower lvs.: lvs. petiolate, 4-6 in. diam., rotundate or reniform, base deeply cordate, incise-crenate to scarcely one-third the depth of the blade the lobes with the edges overlapping: scape scarcely longer than the lvs., bearing 2-6 fls.: bracts lanceolate: fls. pale violet; calyx glabrous, lobed to the middle, the lobes ovate, obtuse, and callous-mucronate; corolla with deeply bifid lobes. Japan. G.M. 58:207. R.H.S. 39:177.

96. *tosaënsis*, Yatabe. Lvs. petiolate, membranaceous, pubescent below, ciliate, about 2 in. diam., base cordate, orbicular or very broadly ovate, slightly lobed, the lobes acute, dentate; the petioles pubescent, subequaling the blades: scape exceeding the lvs., pubescent, glabrescent toward the top, bearing a simple 2-4-fld. umbel or 2 superposed umbels: bracts short, subulate: fls. pale purple; calyx tubular, split scarcely to the middle with narrowly triangular lobes; corolla-tube slightly dilated toward the top, the limb about $1\frac{1}{4}$ in. across, the mouth annular; the lobes ovate, emarginate: caps. long-cylindrical, very much longer than the calyx. Japan. Gn. 79, p. 266.

XI. VERNALES.

Lvs. membranaceous, rugose, gradually attenuate at base (rarely cordate): fls. pedicelled: handsome species: Eu., Asia. This is a group of spring-flowering plants to which the polyanthus and the true cowslip belong. They are much varied and hybridized, and the botany of them is therefore much confused.

A. Limb of corolla concave; calyx open-campanulate.

97. *veris*, Linn. (*P. veris* var. *officinalis*, Linn. *P. officinalis*, Hill. *P. odorata*, Gilib. *P. domestica*, Hoffm. *P. coronaria*, Salisb.). COWSLIP. Fig. 3187. Stemless, minutely soft-pubescent: lvs. rugose, membranaceous or chartaceous, ovate or ovate-oblong, obtuse, more or less contracted or narrowed to the petiole, crenate, more or less pilose or canescent-or white-tomentose below; the petiole winged, shorter than or equaling the blade: scape pubescent, bearing a many-fld. umbel, 4-8 in. high: bracts linear, acute, small: fls. fragrant, bright golden or light yellow, rarely purplish; calyx pubescent, campanulate, more or less broadened, 5-ribbed, whitish, with triangular, acute frequently mucronulate lobes; corolla-limb concave, rarely somewhat flat, expanding little beyond the bulge of the calyx, $\frac{1}{2}$ -1 in. across, with obcordate obtuse emarginate lobes: caps. oval, included in the calyx. S. Cent., and N. Eu., Britain, Asia. G.W. 4, p. 245 (var. *grandiflora*); 13, p. 74; 15 p. 270.

The cowslip is a variable species, with a strong tendency to abnormal development of the calyx. Var. *macrocalyx* (*P. macrocalyx*, Bunge. *P. officinalis* var. *macrocalyx*, Koch), Asian, has calyx about $\frac{3}{4}$ in. long and broadly obconic at base, the lobes short-triangular and acute-mucronate: corolla exceeding calyx, orange-yellow, $\frac{3}{4}$ -1 in. or more across: lvs. usually more or less tomentose or subcanescent beneath (sometimes greenish), attenuate or contracted into a winged petiole.

3185. *Primula Forbesii*, the baby primrose, at the beginning of its blooming season.

Var. *inflata*, Reichb. (*P. inflata*, Duby. *P. canescens*, Opiz. *P. officinalis* var. *canescens*, Beck. *P. pannonica*, Kerner). Calyx equaling or surpassing corolla-tube, more or less open-campanulate, about $\frac{3}{4}$ in. long; corolla $\frac{1}{2}$ – $\frac{3}{4}$ in. across: lvs. contracted or narrowed into petiole, cano-tomentose or glabrescent beneath.

Var. *suaveolens*, Reichb. (*P. Colimnae*, Ten. *P. officinalis* var. *Colimnae*, Pax). Calyx campanulate; corolla-limb little concave or almost plane, about $\frac{3}{4}$ in. across: lvs. ovate to oblong-ovate, cordate, densely white-tomentose beneath.

AA. Limb of corolla plane.

B. Scape evident.

C. Fls. yellow.

98. *elatior*, Hill. OXLIP. Lvs. rugose, membranaceous, ovate or oblong, the apex, obtuse, more or less contracted or narrowed to the petiole, crenulate or denticulate, more or less pilose or canescent-tomentose below; the petiole more or less winged, shorter than or equaling the blade: scape more or less pubescent, 4–8 in. high, bearing a many-fld. umbel: bracts linear, acute, small: fls. pale yellow, turning green in drying, scentless; calyx more or less pubescent, 5-ribbed, tubular, with narrowly lanceolate acute lobes that are shorter than the tube; corolla-tube cylindrical, the limb flat, more or less than $\frac{3}{4}$ in. across, with obcordate, emarginate lobes: caps. cylindrical or oblong, equaling or exceeding the calyx. Eu., especially in the mountains and the northern part, southeast to Caucasus and Persia. Gn. 62, p. 217.

G.W. 15, p. 269.—Var. *gigantea*, Hort., is offered, with fls. more than 1 in. across, yellow predominating. For cowslip $\times$ oxlip, see New Phytologist, vi:162 (1907).

From the cowslip the oxlip differs in having the fls. more or less upright, the corolla-limb is plane and the throat is open without folds. The species is widely variable. Var. *carpathica*, Griseb. Lvs. ovate or oblong, the petiole more or less winged and the blade strongly rugose and crenulate: calyx usually ventricose-tubular before flowering: caps. cylindrical. Carpathians. Var. *intricata*, Pax. Lvs. ovate-elliptic, gradually attenuate into a winged petiole, little rugose, green beneath: scape only equaling the lvs.: calyx tubular, the lobes triangular and acute: caps. short-cylindrical, equaling or perhaps exceeding the calyx. S. Eu. Var. *Pallasii*, Pax (*P. Pallasii*, Lehm. *P. altaica*, Pall.). Lvs. oblong or elliptic, gradually attenuate into petiole, nearly glabrous, little or not at all rugose: calyx very narrowly tubular, the lobes very narrow and recurved at apex. Urals, Caucasus, N. Persia, Altai. Var. *cordifolia*, Pax (*P. cordifolia*, Rupr.). Lvs. round-ovate, cordate at base, the petiole wingless or narrowly winged, nearly glabrous, scarcely rugose: calyx very narrowly tubular, the lobes very narrow and at apex recurved. Caucasus and Armenia.

99. *pseudoelatior*, Kusn. Differs from *P. elatior* in calyx-lobes being broad-lanceolate and about equaling the length of the tube: lvs. ovate, hairy, rugose, green beneath,

abruptly contracted into petiole, the base cordate to truncate: scape exceeding the lvs., bearing a simple umbel: corolla yellow, with plane limb: caps. rounded, much shorter than calyx. Caucasus.

100. *leucophylla*, Pax. Differs from *P. elatior* in the lvs. being densely white-tomentose beneath: lvs. somewhat coriaceous, oblong or elliptic, obtuse, rugose, petiolate: scape exceeding the lvs., pubescent but becoming more or less glabrescent, bearing a many-fld. umbel: corolla yellow, scarcely exceeding the calyx, the limb plane, lobes obcordate: caps. cylindrical, equaling or less than the calyx. Carpathians.

CC. Fls. violet, rarely white.

101. *amœna*, Bieb. Lvs. submembranaceous, somewhat roughened or thin, narrowed to the petiole or abruptly and longer petioled, in which case the base is cordate or subcordate, sometimes minutely denticulate or subentire, sometimes decidedly coarse-crenate, ashy tomentose or glabrous below; the petiole equaling the blade: scape 1–5 in. high, exceeding the lvs., bearing a many-fld. umbel: bracts short-lanceolate, acuminate; fls. purple or lilac, rarely white; calyx narrowly tubulate, with lanceolate acuminate lobes; corolla-tube cylindrical, the limb flat, $\frac{3}{4}$ – $1\frac{1}{4}$ in. across, with obcordate emarginate lobes: caps. cylindrical, equaling or exceeding the calyx. Caucasus region to Asia Minor, in several varieties. B.M. 3252.

BB. Scape none or nearly none, the umbels therefore borne in the foliage and the fls. standing singly on the long rays.

C. Lvs. not white-tomentose beneath.

102. *acaulis*, Hill (*P. vulgaris*, Huds. *P. veris* var. *acaulis*, Linn.). PRIMROSE. Lvs. many, tufted, somewhat wrinkled, membranaceous, oblong or obovate-oblong, apex obtuse, gradually rarely evenly narrowed to the petiole which is shorter than the blade, sometimes sessile, more or less pilose or glabrescent, crenulate; the petiole more or less winged: scape none; pedicels $2\frac{1}{2}$ –4 in. long, more or less equaling the lvs., soft-pubescent, as is the calyx: fls. pale yellow, or rarely purple or blue, becoming greenish in drying; calyx ovate-tubular, 5-ribbed with narrow-lanceolate, acuminate lobes; corolla-tube cylindrical, the limb flat, 1– $1\frac{1}{2}$ in. across, with obcordate emarginate lobes, the throat slightly contracted and bearing a circle of scale-like folds: caps. ovate, included in the calyx. Eu., widely distributed and well known. B.M. 229. Var. *rubra*, Sibth. & Smith. *P. Sibthorpiae*, Hoffmg.), has rose-colored or purple fls. E. Medit. region. A. *arisiaca*, Stapf, is a hybrid of *P. acaulis* and *P. elatior*. *P. Croussei*, Hort., is probably a garden form of *P. acaulis* or one of the hybrid derivatives. For pictures of various forms of *P. acaulis* or *vulgaris*, see Gn. 7, pp. 319, 345; 11, p. 127; 12:496; 29, p. 385; 54:142, and pp. 142, 143. A.F. 13:1102. Gng. 6:245. R.H. 1880: 90; 1898:12. In cult., the primrose runs into many forms and colors, some of them double-fld. More or less caulescent forms (var. *caulescens*, Hort.) are probably hybrids.

103. *Polyantha*, Hort. Fig. 3188. A garden group supposed to be hybrids of *P. veris* or *P. elatior* and *P. acaulis*, although some botanists refer it to *P.*

3186. *Primula Forbesii*. ($\times \frac{1}{2}$)

3187. The cowslip.—*Primula veris*. ($\times \frac{1}{4}$)

elatio direct, and some consider it to be a direct development of *P. acaulis*, with elongated scapes. Whatever its origin, the group is distinct for garden purposes, and it is the commonest form of hardy primula known in American gardens. The fls. are several to many in an erect umbel that usually stands well above the long lvs.; the colors are mostly yellow and red-and-yellow, running into orange, bronze, and maroon, and sometimes pure white. Gn.M. 2:59.—There is a form with one corolla inside the other, known as duplex or hose-in-hose. The polyanthus is perfectly hardy, blooming in earliest spring. Prop. easily by seeds sown as soon as fully ripe; also by division. *P. variabilis*, as used in horticultural literature, usually refers to this Polyanthus group or to plants of similar origin.

cc. Lvs. white-tomentose beneath.

104. *Julia*, Kuhn. Lvs. thin, glabrous, reniform-orbiculate or ovate-orbiculate, base cordate, coarsely crenate, abruptly passing into the somewhat winged petiole which is 2-3 times as long as the blade: scape none: pedicels numerous, 2-3 times longer than the lvs.: fls. rose or red; calyx glabrous, narrowly tubular, angled, with narrow-lanceolate very acuminate lobes; corolla-limb flat, $\frac{3}{4}$ -1 in. across, with narrow deeply obovate lobes. Transcaucasus. Intro. 1910. B.M. 8468. G.C. III. 51:293. R.H. 1914, p. 251. Gn. 78, p. 194. G. 35:327.—Said to be a free grower, liking moisture, and producing its red fls. in profusion.

XII. SOLDANELLOIDEÆ.

Lvs. more or less hairy or pubescent: fls. sessile or very nearly so: involueral bracts short and broad: Himalaya, China.

A. Infl. spicate.

105. *spicata*, Franch. Lvs. membranaceous, short-pubescent on both surfaces, petiolate, with the petiole $1\frac{1}{2}$ -3 in. long, ovate or oblong-ovate, obtuse, short-attenuate at base, double-serrate; the petiole narrowly winged and shorter or longer than the blade: scape slender, 2-3 times longer than the lvs., glabrous, short-pubescent toward the top: infl. elongated, 1-sided, spicate: bracts lanceolate: fls. sessile, horizontal or somewhat pendulous, violet; calyx campanulate, sparsely white-farinaceous, triangular, acute; corolla-tube short, abruptly dilated into a broad flattened cup-shaped limb, ovate, emarginate, the apex erose-dentate: caps. globose, about equaling the calyx. China. Intro. 1908. R.H.S. 39:157.

AA. Infl. capitate or umbellate (fls. sometimes solitary).

B. Fls. several or many.

106. *Wattii*, King (*P. Gillii*, Hort.). Lvs. covered with flexuous white hairs especially on the nerves and margin, glabrescent, membranaceous, oblong-lanceolate, gradually narrowed to the petiole which equals the blade, coarsely crenate-dentate, the teeth entire or crenulate: scape $4\frac{1}{2}$ -6 in. high, many-fl., glabrous: bracts membranaceous: fls. sessile, nodding, violet; calyx open cup-shaped, membranaceous, with lobes which are quadrate or semi-orbicular in outline and dentate; corolla glabrous, the limb broad-funnelform, broad-obcordate, emarginate as well as crenulate. Sikim-Himalaya. B.M. 8456 G.C. III. 51:286. Gn. 76, p. 191. R.H.S. 39:192.

107. *florida*, Balf. f. & Smith. Lvs. long-stalked, the blade ovate, covered beneath with white meal (farina): scape very much overtopping the lvs., which spread on the ground: fls. in umbel, short-stalked, with mealy calices, the corolla purple-blue, and rapidly fading to paler tint. Yunnan, China. G.C. III. 57:207.—A humus-loving species.

108. *dryadifolia*, Franch. Glabrous: lvs. small, ovate crenulate, contracted to a petiole about $\frac{1}{2}$ in. long or subcordate, white-farinose below or devoid of farina:

scape 2-3 times longer than the lvs., puberulent, bearing 3-5 fls. which are clustered: bracts broad-ovate, sometimes tridentate, green or becoming purple, sparsely farinose: fls. subsessile, violet; calyx broadly campanulate, split scarcely to the middle with ovate, obtuse, entire or minutely crenulate lobes; corolla-limb flat, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with noticeable 4-lobulate lobes: caps. ovate-oblong, about equaling the calyx. China. Intro. 1911.

109. *pinnatifida*, Franch. Lvs. clothed with soft, white hairs especially so on the nerves and margin, petiolate, $1\frac{1}{2}$ in. or less long, ovate or oblong, base cuneate, entire, or else incise-lobed, the lobes quadrate or ovate, the lower and upper smaller, entire, the intermediate variously lobed; the petioles narrowly winged,

3188. Polyanthus.—*Primula Polyantha*. ($\times \frac{1}{4}$) No. 103.

equaling the blades: scape 2-3 times longer than the lvs., glabrous, somewhat farinate toward the top: bracts lanceolate, acuminate, frequently colored: fls. capitate, reflexed, violet; calyx becoming violet, sparsely golden-farinose, campanulate, with ovate, obtuse lobes frequently denticulate or erose at the apex; corolla-tube cylindrical, the limb cup-shaped, less than $\frac{1}{2}$ in. across, with ovate, entire or scarcely emarginate lobes. China. Intro. 1908. R.H.S. 39:156.

110. *cérnua*, Franch. Closely allied to *P. pinnatifida*, whose fls. have similar capitate infl., differs however in having the lvs. broadly ovate, short, indistinctly petiolate, margins scarcely conspicuously crenulate: bracts of the involucre ovate not lanceolate: calyx-lobes ovate, mucronate not rounded or crenulate at the apex: fls. blue. China.

BB. Fls. few or only 1.

C. Blossoms large for the plant.

111. *Reidii*, Duthie. Lvs. membranaceous, upper surface convex, puckered, laxly silky-villous, oblanceolate, obtuse, coarsely lobulate-dentate or -crenate, narrowed to a winged petiole which is shorter than the blade: scape stiff, up to 4 in. high, several-fl.: bracts broad: fls. subsessile, nodding, ivory-white; calyx campanulate, white-farinose inside, with broad, rotundate, obtuse, glandular-ciliate lobes; corolla-lobes broad-oblong, closed in a globe almost $\frac{3}{4}$ in. diam., the apex 2-cleft with a tooth between. Himalaya. B.M. 6961. G.C. II. 26:693; III. 49:195. Gn. 77, p. 231. G.M. 58:288. R.H.S. 39:185.

112. *uniflora*, Klatt. Devoid of farina, small: lvs. small, membranaceous, sparsely white-villous, broad-ovate or orbicular-ovate, acute, base truncate or acute, incise-dentate or crenate; the petiole slender, equaling or exceeding the blade: scape slender, long, exceeding the lvs., 1-2-fld.: bracts minute, oblong: fls. large in relation to the plant, sessile, nodding, pale violet; calyx campanulate, membranaceous, deeply 5-lobed, the lobes quadrate, truncate, apiculate, frequently undulate-crenulate; corolla funnelform, the limb almost $1\frac{1}{4}$ in. across with broad, coarsely dentate lobes: caps. globose. Sikkim-Himalaya. R.H.S. 39:186.

113. *pusilla*, Wall. Plant minute, caespitose, small-lvd., small-fld., and the habit of an androsace: lvs. less than $\frac{1}{2}$ in. long, spreading-recurved, spatulate or oblanceolate, obtuse, pinnatifid, somewhat strigose-pilose above, more or less puberulous below, the midrib stout, toward the base narrowed to a petiole which can scarcely be distinguished from the blade: scape slender, about 2 in. high, bearing 1-4 fls. in a head: bracts ovate-lanceolate: fls. purple or violet; calyx farinose, campanulate, with triangular acute lobes; corolla-tube densely villous at the throat, the limb almost $\frac{3}{8}$ in. across, with spreading, obcordate, emarginate lobes; ovary depressed-globose. Himalaya. B.M. 7079. R.H.S. 39:208.

cc. Blossoms small for the genus: plant minute.

114. *sapphirina*, Hook. f. Very small and densely caespitose, small-lvd. and small-fld., glabrous or nearly so: lvs. $\frac{1}{4}$ - $\frac{1}{2}$ in. long, cuneo-spatulate or obovate, narrowed into petiole, pinnatifid: scape slender, 1-2 in. high, 1-4-fld.: bracts minute, lanceolate: fls. very short-pedicelled, nodding, capitate or essentially so, violet; calyx cup-like with triangular lobes; corolla funnelform, with short tube, scarcely surpassing the calyx, the limb about $\frac{1}{2}$ in. diam., lobes ovate and emarginate. Sikkim, 12,000 to 15,000 ft. altitude. B.M. 6961.

XIII. CAPITATÆ.

Much like the *Soldanelloideæ*, but bracts subulate or lanceolate: fls. sessile or pedicelled: W. Himalaya to China.

a. Fls. erect; calyx tubular-campanulate.

115. *erösa*, Wall. (*P. capitata* var. *crispa*, Hort. *P. denticulata* var. *erösa*, Duby). Glabrous or puberulous, 5-7 in. high: lvs. appearing with the fls., not farinose, somewhat pellucid, slender reticulate-veined, obovate-spatulate or oblanceolate, obtuse, gradually narrowed to the petiole which can scarcely be distinguished from the blade, sharply erose-denticulate: scape slender, 8-10 in. high, much exceeding the lvs., bearing a many-fld. umbel: bracts small, triangular, farinose: fls. purple or violet; calyx open tubular-campanulate, the tube short, with lanceolate acute lobes; corolla-limb about $\frac{1}{2}$ in. across, with obcordate emarginate lobes: caps. included in the calyx. Temp. Himalaya. B.M. 6916 A. Gt. 2, p. 130. Gn. 62, p. 131. G.L. 16:95. R.H.S. 39:187.—Said to require a moist place or a bog in the rock-garden. Hooker says that the lvs. are sometimes 18 in. long.

116. *denticulata*, Smith. Scapes 4-18 in. tall, bearing a dense umbel or head of pale purple fls.: lvs. in a rosette on the crown, usually not full grown until the fls. are past, and surrounded beneath by short, broad, thick, lf.-like bracts; lf.-blades oblong-obovate or spatulate, usually narrowed into a winged stalk, sharply denticulate, more or less mealy: corolla-tube about twice as long as the calyx-teeth, the corolla-lobes obcordate. Himalaya region, 7,000-13,000 ft., and said by Hooker to be "the commonest Himalayan primula, and very variable." The fls. are said to be eaten in salad and the powder of the roots to be used in killing leeches. Intro. 1842. B.M. 3959. B.R. 28:47. Gn. 11, p. 127; 29, p. 382; 35, p. 529; 41, p. 588; 62, p. 218; 79, p. 161.

G.M. 54:344. G.C. III. 47:152. J.H. III. 62:261; 67:529. R.H.S. 39:160.—A hardy plant, usually treated as a rockwork subject. Blooms in earliest spring. Var. *purpurea*, Hort., has dark purple fls. Var. *alba*, Hort., has white fls. Gn. 50, p. 372; 78, p. 165. G.L. 23:422. Gn. W. 22, suppl. May 13 (as var. *alba grandiflora*). Var. *pulcherrima*, Hort., is very robust, with deep purple fls. in dense heads. Var. *variegata*, Hort., has lvs. bordered white. Var. *Fire Ball* has bright purple fls. in large heads.

Var. *cachemiriäna*, Hook. f. (*P. cachemiriäna*, Munro. *P. cashmeriäna*, Hort.). Lvs. nearly or quite full grown when the fls. are in bloom, usually more mealy (yellow-mealy beneath and sometimes on top): fls. rich purple with yellow center: perhaps a hybrid. W. Himalayan region. R.H. 1880:330. J.H. III. 60:199. Gn. 79, p. 97. *P. sibirica* var. *kashmiriana*. (B.M. 6493) is a different plant. See No. 132.

117. *pseudodenticulata*, Pax. Glabrous: lvs. chartaceous, appearing with the fls., linear-oblong, obtuse or acute, scarcely noticeably denticulate, almost entire, not farinose, gradually narrowed to the winged petiole: scape stiff, exceeding the lvs., $1\frac{1}{2}$ -4 in. high, sparsely farinose below the top, bearing a head of many fls.: bracts lanceolate, acuminate from a broad base: fls. lilac, the outer ones of the head opening long before the inner ones; calyx tubular-campanulate, white-farinose, with narrowly triangular, obtuse pilose lobes which do not turn black; corolla-limb annulate at the throat, about $\frac{1}{2}$ in. across, with broad-obcordate, deeply emarginate lobes. S. W. China. Intro. 1908. G.C. III. 53:264.—Another recent species of this group is *P. nessensis*, Forr., with bright pink fls., "of considerable merit" for both indoors and outdoors; scape slender and much overtopping the oblong-rugose or bullate lvs. R.H.S. 39:160. It is said that this is the name for the plant that has been distributed as *P. farinosa* var. *Beesii*, and also for some of the *P. pseudodenticulata*.

118. *gläbra*, Klatt. Lvs. not farinose, membranaceous, small for the size of the plant (about $\frac{1}{2}$ in. long), ovate-spatulate, obtuse, erose-dentate, attenuate into a narrow petiole-like base: scape slender, 2-3 in. high, bearing a close head-like umbel: bracts small, acute: fls. purple-violet, very short-pedicelled; calyx tubular-campanulate, incised or cut scarcely one-third the length, the lobes obovate and very obtuse; corolla-tube scarcely exceeding the calyx, the lobes narrowly obcordate and bifid. Sikkim-Himalaya, 12,000-15,000 ft. and more altitude. R.H.S. 39:192.—Apparently cult. only very recently.

AA. Fls., or the outer ones, reflexed, nodding or pointing downward; calyx mostly globose-campanulate. (Some of the plants of this group have been associated by Balfour as a section *Muscarioides*, with a muscari-like flower habit. "The characteristic feature of the group is the aggregation of small fls., which have tubular corollas with a short erect limb, in a close spike or capitulum, in which they are all inserted with the mouths of the corollas downwards.")

b. Calyx-teeth acute.

119. *capitata*, Hook. Lvs. appearing with the fls., oblong-lanceolate, obtuse or acute, finely denticulate, more or less intensely white-farinose below, narrowed to the petiole, which is shorter than the blade and frequently scarcely distinct from it: scape 8-16 in. high, stout, slightly thickened toward the top, bearing a dense, rarely a little lax, many-fld. head: bracts lanceolate, acute: fls., the outer ones, opening long before the inner, reflexed or nodding, the inner forming a dense crown, bright purplish blue; calyx open-campanulate, scurfy, split to the middle, with the lobes triangular acute, rather concave, about $\frac{1}{2}$ in. across with obcor-

XCII. A plant of *Primula obconica*.

date emarginate lobes. Himalaya. B.M. 4550. F.S. 6:618. Gn. 16:534; 29, p. 382; 45, p. 503; 50, p. 373; 54, p. 467; 76, p. 183; 79, p. 124. J.H. III. 32:209; 50:407. J.F. 1:80. In China this species is represented by forms regarded as distinct species, as in Nos. 120 and 121. Var. *grandiflora*, Pax, is a culture-form with large fls. in a more open head, the fls. being very short-pedicelled. B.M. 6916 B.

120. *pseudocapitata*, Ward. A Chinese (Yunnan) representative of *P. capitata*, with smaller trusses of purple fls.; bracts cut. Intro. 1911.

121. *sphaerocéphala*, Balf. f. & Forr. Much like *P. capitata*, with small globular heads, the fls. purplish inside, not annulate, bracts fimbriate; delicately perfumed. S. W. China.—This and No. 120 are distinguished from No. 119 by the much smaller corolla-limb and more globular heads.

122. *Giraldiana*, Pax (*P. muscarioides*, Hemsl.). Not farinose, 8–12 in.: lvs. flaccid, very thin-membranaceous, glabrescent, the younger ones cobwebby-pilose below, especially on the nerves, narrowly oblong, acute or obtuse, lobulate-crenate-dentate, long-narrowed to a winged petiole which is shorter than the blade: scape 8–12 in. high, glabrous, bearing a many-fld., globose-cylindrical head: fls. strictly sessile, reflexed, blue; calyx open-campanulate, split below the middle, with ovate, acute, denticulate, ciliate lobes; corolla-tube slender, the limb rather concave, about $\frac{1}{4}$ in. across, with broad-ovate, entire, very obtuse not emarginate lobes: caps. globose, little exceeding the calyx. Shensi, in Cent. China. Intro. 1908. B.M. 8168. R.H.S. 39:153.—Said to require a moist and somewhat shaded place.

BB. *Calyx-teeth obtuse.*

C. *Corolla-lobes less than half the exerted part of the tube.*

123. *deflexa*, Duthie. Rootstock short and rather stout: lvs. rosulate, rather thin, 5–11 in. long, narrowly oblanceolate, obtuse or subacute at apex, tapering to long winged petiole, minutely white-hairy, irregularly crenate-dentate, the teeth with reddish gland-like tips: scape often 2 ft. high, much exceeding the lvs., bearing nearly globose heads about 1 in. diam. of crowded sessile deflexed dark blue or rose-purple fls. with a delicate blue center and which often turn whitish after expansion: calyx about $\frac{1}{4}$ in. long, yellow-farinose, unequally lobed; corolla about $\frac{1}{2}$ in. long, glabrous, funnel-shaped, the lobes cuneate-oblong and broadly emarginate: caps. depressed-globose in form. W. China, 10,000–13,000 ft. altitude. Intro. 1906. R.H.S. 39:153.

124. *bellidifolia*, King. Puberulous: lvs. thin-flaccid, not farinose, oblanceolate or spatulate, irregularly sublobately dentate, obtuse, narrowed to a petiole more or less equaling the blade: scape 4–8 in. high, glabrous, exceeding the lvs., bearing a dense many-fld. head: bracts small: fls. reflexed, purplish blue; calyx open-campanulate, puberulent, split below the middle, with ovate obtuse farinose lobes; corolla-tube slender, the throat constricted, annulate, the limb about $\frac{1}{4}$ in. across, concave, with obcordate lobes: caps. globose. Sikkim.

125. *Watsonii*, Dunn. Lvs. sessile and rosulate, 3–6 in. long, oblanceolate, obtuse, long-attenuate at base, more or less lobulate-crenate, hirsute on veins and not farinose: scape strict, very much exceeding the lvs. (to 1 ft. high), glabrous, farinose at apex, bearing a small globose or ovate spike or head of many sessile deep purple fls. which are $\frac{1}{3}$ – $\frac{1}{2}$ in. long: calyx broad-campanulate, the 5 broad-ovate ciliate teeth equaling the tube; corolla glabrous, dark purple, the tube cylindrical, the limb cup-shaped, the lobes truncate or obtuse: caps. ovoid. W. Szechuan, China.—Scapes powdery yellow. Intro. 1911. R.H.S. 39:157.

cc. *Corolla-lobes more than half as long as the exerted part of the tube.*

126. *Littoniana*, Forr. Plant 2 ft. or more, with spikes resembling those of *kniphofia*: lvs. broadly lanceolate, attenuate into petiole, rounded at apex, irregularly dentate, hairy, about 8 in. long: scape thick, erect, much exceeding the lvs., farinose toward the top, bearing a dense many-fld. elongated spike (which is 3–5 in. long) of violet-blue, sessile or short-pedicelled fragrant fls.: bracts linear, farinose: calyx broadly campanulate, deeply cut or split, the scarlet lobes ovate or ovate-lanceolate and acute; corolla-tube exceeding calyx, the limb concave and about $\frac{1}{2}$ in. diam., the lobes narrow-ovate and entire with rounded apex: caps. small, globose, not exceeding the calyx. S. W. China, 10,000–11,000 ft. altitude. Intro. 1908. B.M. 8341. G.C. III. 46:14, 15. Gn. 73, p. 361. G.M. 52:528. R.H.S. 39:156.—“Named to commemorate the late Consul Litton of Tengyveh.” *P. Vièli*, Franch., is very like this species but smaller and lacking the hairs; the plant described under this name in Pax’s monograph is said to be a chimera or confusion of *P. deflexa*, *P. gracilenta*, and *P. Watsonii*. *P. cernua* (No. 110) is by recent authors associated with this group.

127. *gracilenta*, Dunn. Perennial, not farinose: lvs. petioled, in rosettes, oblong and obtuse, narrowed at base, irregularly dentate and wavy, hairy: scape slender, 6–8 in., bearing a head of sessile deflexed deep lilac fls., subtended by lanceolate bracts; calyx broad-campanulate, the teeth ovate and more or less ciliate; corolla with cylindrical tube, the lobes oblong and terminated by short tail, giving a fringed effect to the corolla. Yunnan. Intro. 1915. G.C. III. 57:207.—A humus-loving species.

XIV. FARINOSÆ.

Lvs. glabrous or minutely pubescent: involucrel bracts gibbose or saccate at base: widespread in arctic and subarctic regions of both hemispheres and in mountains of Eu., Asia, to Japan.

A. *Fls. sessile or very nearly so.*

128. *algida*, Adam. Farinose or not so: lvs. glabrous, oblong-spatulate or oblong, obtuse, gradually narrowed to a short, frequently obscure, winged petiole, minutely and sharply denticulate or subserrate, rarely with the lower margin subentire: scape exceeding the lvs., 1–8 in. high, bearing a frequently many-fld. umbelliform head: or rarely a congested umbel: bracts lanceolate, acuminate, their base subsaccate: fls. violet; calyx split to the middle, the teeth lanceolate, rather obtuse or rather acute, black, rarely green; corolla-limb about $\frac{3}{8}$ in. across, with obcordate trifid lobes: caps. oblong, more or less equaling the calyx. Caucasus, Asia, and Asia Minor, in several marked forms. Gn. 78, p. 180. R.H.S. 39:96.—For shady cool parts of rock-garden; May, June.

129. *auriculata*, Lam. (*P. longifolia*, Curt.). Lvs. glabrous, not farinose, membranaceous, elliptic, lanceolate or oblong-spatulate, obtuse, remotely and minutely denticulate or subentire, narrowed to a short, often obscure petiole: scape exceeding the lvs. 4–14 in. high, bearing a many-fld. umbelliform head, sparsely farinose or not so below the infl.: bracts linear-lanceolate, acuminate, more or less auriculate: fls. rose, violet, or lilac with a whitish eye; calyx split two-thirds to three-fourths its length, the teeth lanceolate, rather obtuse or rarely rather acute, often colored at their apex; corolla-limb $\frac{1}{2}$ – $\frac{3}{4}$ in. across, with obcordate lobes: caps. ovate or rotundate, slightly exceeding the calyx or not. Mountains of Greece to Persia. B.M. 392. Gt. 1874, p. 225.

130. *capitellata*, Boiss. Lvs. farinose or becoming bald, ligulate-lanceolate or subspatulate, narrowed to

an often obscure petiole, obtuse or rather acute, obsoletely and sparingly denticulate or subentire, rarely sharply denticulate: scape exceeding the lvs. or (in alpine forms) more or less equaling them, $1\frac{1}{2}$ –10 in. high, bearing a densely fld. subsessile head: bracts oblong-lanceolate, obtuse base produced below the place of insertion: fls. rose; calyx split one-third to one-half its length, with ovate, obtuse lobes which become black; corolla-limb less than $\frac{1}{4}$ in. across, with short obcordate lobes: caps. globose, about as long as the calyx. Persia and Afghanistan. G. 31:49.

AA. Fls. distinctly pedicellate (pedicels short in No. 139).

B. Lvs. distinctly petiolate, the blade usually gradually contracted at base, the petiole not winged.

c. Lf.-margin entire.

131. *involucrâta*, Wall. (*P. Munroi*, Lindl. *P. Traillii*, Wilson). Fig. 3189. Not farinose: lvs. leathery, becoming somewhat glaucous, ovate, oblong, or deltoid-orbicular, obtuse, very entire or obsoletely and minutely denticulate, suddenly contracted to a petiole which exceeds the blade: scape much exceeding the lvs., 4–12 in. high, slender, bearing a 3–6 to many-fld. umbel: bracts linear, their base spurred with appendages: fls. white; calyx glabrous, tubular, 5-ribbed, with narrowly triangular subacute lobes; corolla-throat annulate, yellowish, the limb about $\frac{3}{4}$ in. across, lobes obcordate. Himalaya. F.S. 10:1023. Gt. 1863: 394. G.C. III. 22:263 (reduced in Fig. 3189). Gn. 79, p. 197. R.H.S. 39:209.—Needs a moist position.

3189. *Primula involucrata*.
($\times \frac{1}{4}$)

132. *sibirica*, Jacq. Plant wholly green: lvs. pale green, membranaceous, glabrous, elliptic-orbicular or ovate, very entire or rarely with a tendency to be denticulate, suddenly contracted to a petiole which almost equals the blade: scape exceeding the lvs., 2–7 in. high, slender, bearing a lax, few-fld. umbel: bracts oblong, obtuse, their base appendaged-saccate: fls. lilac or pink; calyx glabrous, tubular, 5-ribbed, with short, rather obtuse lobes; corolla-throat naked, the limb about $\frac{1}{2}$ in. across or less, with obcordate deeply emarginate lobes: caps. cylindrical, exserted from the calyx.

Var. *integrifolia*, Pax (*P. integrifolia*, Eder. *P. sibirica* var. *kashmiriana*, Hook. f.), has fls. mostly smaller, the corolla-tube scarcely exceeding the calyx, and the corolla-lobes narrower. B.M. 6493. Var. *brevicalyx*, Trautv., has corolla-tube twice or more longer than calyx. Arctic and alpine regions of the northern hemisphere. B.M. 3167 (as *P. sibirica*); 3445 (as var. *integerrima*). G.C. III. 41:350 ("the small variety"). Gn. 78, p. 412. G. 37:247. G.M. 56:963.

133. *conspersa*, Hort. Veitch. Allied to *P. sibirica*: lvs. finely but variably serrate, about $1\frac{1}{2}$ in. long and $\frac{1}{2}$ in. broad, erect, firm in texture, not farinose, fls. rather more rosy: scape about 9 in. high, farinose, bearing an umbel about 12-fld.: fls. about $\frac{3}{4}$ in. across, pale lilac: later than *P. farinosa* and with taller scapes and larger fls. W. Kansu, China.

134. *tibetica*, Watt (*P. pumilio*, Pax). Not farinose, dwarf: lvs. leathery, glabrous, elliptical, acute or obtuse, very entire, contracted to a petiole which almost equals the blade: scape very short, $\frac{3}{4}$ in. (frequently less) high, bearing 1–5 fls.: bracts linear-oblong, their base hardly gibbous: fls. rose or blue; calyx tubular, 5-angled, with short-triangular obtuse lobes; corolla-throat annulate, the limb hardly $\frac{3}{4}$ in. across, with deeply obcordate lobes: caps. long-exserted, cylindrical. High mountains of Thibet.

cc. Lf.-margin more or less denticulate.

D. Involucral bracts scarcely gibbous at base.

135. *Knuthiana*, Pax. Farinose, not hairy: lvs. membranaceous, oblong-ovate or lanceolate, acute or obtuse, narrowed to a winged petiole which is distinguishable from the blade or scarcely so and is equal to or shorter than the blade, densely farinose below, denticulate: scape equaling or exceeding the lvs., 4–5½ in. high bearing a many-fld. lax umbel: bracts broad subulate-acuminate from the base which is scarcely gibbous: fls. violet; calyx open-campanulate, split to the middle with triangular acute lobes; corolla-throat constricted, the limb about $\frac{1}{2}$ in. across, with obcordate deeply emarginate lobes: caps. globose, included in the calyx. China, in two or more forms. G.C. III. 51: suppl. May 25. G.M. 55:254. F.E. 33:975. R.H.S. 39:160.

136. *frondosa*, Janka. Farinose or entirely devoid of farina, not hairy: lvs. very thin-submembranaceous, the inner ones finally becoming elongated, cuneate-oblong or when obovate, obtuse, gradually narrowed to a petiole which equals or exceeds the blade, sharply denticulate or when mature wavy-crenulate, a little undulate: scape exceeding the lvs., $1\frac{1}{2}$ –4 in. high, bearing a many-fld. lax umbel: bracts small, linear-lanceolate, their base not saccate: fls. bright blue; calyx tubular-campanulate, with triangular acute lobes; corolla-limb almost $\frac{1}{2}$ in. across, with obcordate, bifid-emarginate lobes: caps. cylindrical, equaling or half longer than the calyx. Balkans. Gn. 71, p. 323; 72, p. 167; 76, p. 194. Gn.W. 25:529. G. 36:534. R.H.S. 39:97.—It has been stated that the plant in cult. under this name is not the plant of Janka, but this is probably an error (see Roy. Hort. Soc. 39, pp. 103, 178).

DD. Involucral bracts somewhat saccate at base.

137. *efarinosa*, Pax. Not farinose, very glabrous: lvs. membranaceous, $1\frac{1}{2}$ in. (more or less) long, oblong-ovate, obtuse, sharply erose-denticulate, narrowed into a winged petiole which equals or is shorter than the blade: scape exceeding the lvs., 5–7 in. high, bearing a lax, many-fld. umbel: bracts acuminate from a saccate base: fls. violet; calyx tubular-campanulate, not split to middle with shortly triangular, subobtuse lobes; corolla-tube not constricted at the throat, the limb about $\frac{1}{2}$ in. across, with narrowly obovate, deeply emarginate-bifid lobes: caps. globose, included in the calyx. Cent. China.

138. *dariatica*, Rupr. Plant farinose or not so, glabrous: lvs. $\frac{3}{4}$ –2½ in. long, soft, obovate-lanceolate, oblong or spatulate, obtuse, sharp-denticulate or serrate, suddenly cuneate-attenuate to a petiole which is longer or shorter than the blade: scape equaling or exceeding the lvs., bearing a few- or many-fld. umbel: bracts linear, their base somewhat saccate: fls. rose; calyx subglobose, split to the middle, with oblong, subacute, greenish lobes; corolla-limb less than $\frac{1}{2}$ in. across, with obcordate, bifid lobes: caps. exceeding the calyx. Caucasus region. R.H.S. 39:176.

139. *elliptica*, Royle. Not farinose: lvs. small ($\frac{1}{2}$ –¾ in. diam.), membranaceous, glabrous, glaucous beneath, orbicular to elliptic, obtuse, strongly dentate, petioled, with base dilate and vaginate: scape exceeding lvs., 4–5 in. tall, somewhat flexuose, bearing a 3–10-

fld. nodding umbel: bracts linear and obtuse, dilated and saccate at base, exceeding the short pedicels: fls. rose-colored; calyx campanulate-tubular, cut to the middle, the lobes triangular and somewhat obtuse; corolla exceeding calyx, the limb more than $\frac{1}{2}$ in. across, the lobes obovate: caps. included in calyx. W. Himalaya, Tibet.

BB. *Lvs. scarcely distinctly petiolate, the base of blade short-attenuate, the petiole winged.*

c. *Fls. yellow.*

140. *lutèola*, Rupr. Not farinose, glabrous: lvs. membranaceous, long lanceolate-elliptic, obtuse, denticulate, gradually narrowed to a petiole which is very frequently scarcely distinguishable from the blade: scape exceeding the lvs., 4-6 in. high bearing a densely many-fld. umbel: bracts lanceolate acute, their base saccate-produced: fls. pale sulfur-yellow; calyx campanulate, split two-thirds its length, with lanceolate acute lobes; corolla-limb about $\frac{1}{2}$ in. across, with obovate lobes. E. Caucasus regions. G.M. 58:264.

cc. *Fls. rose, lilac, or purplish.*

d. *Corolla-tube little if at all exceeding the calyx, or only twice or less as long.*

141. *rōsea*, Royle. Fig. 3190. Tufted, with rhizome bearing somewhat lf.-like scales, plant 4-8 in. tall, glabrous, not mealy: lvs. many, oblong-obovate or oblanceolate, crenulate or small-toothed: fls. few to many in a rather loose head (each fl. distinctly stalked), rose-red, more or less drooping, the tube somewhat exceeding the long sharp calyx-teeth, the lobes obovate. W. Himalaya. B.M. 6437. Gt. 1879:994. Gn. 16:12; 29, p. 382; 31, p. 597; 39, p. 417; 62, p. 82; 77, p. 193; 79, p. 161. G. 14:110. R.H.S. 39:208. G.C. II. 19:540. F.M. 1879:360. R.H. 1880:330.—One of the best of the alpine primulas. Var. *grandiflora*, Hort., has large fls. Gn. 50:372. *P. magnifica*, Hort., is a German seedling from *P. rosea* var. *grandiflora*: lvs. coarsely toothed, gray-white when full-grown. Intro. 1904.

142. *Ólgæ*, Regel. Glabrous, not farinose: lvs. about $\frac{1}{2}$ -1 in. long, obovate-oblong, obtuse, narrowed into broadly winged petiole, crenulate-denticulate: scape about 3 in. tall, exceeding the lvs., bearing a dense umbel of rose-lilac fls.: bracts lanceolate, acute, somewhat saccate at base; calyx green and purple-striped, the lobes lanceolate and acute; corolla-tube twice as long as calyx, the lobes obovate and bifid. Turkestan.—Alpine garden; late spring and early summer.

143. *farinosa*, Linn. (*P. Warei*, Stein). Fig. 3191. Farinose at least when young: 4-8 in.: lvs. variable in size, glabrous, veiny, elliptic-lanceolate, obovate or ovate-rotundate, obtuse, frequently gradually narrowed to a petiole which is scarcely distinguishable from the blade, denticulate or subentire: scape exceeding the lvs. $\frac{1}{2}$ -12 in. high, sometimes slender, sometimes stout, bearing a rather dense or lax many-fld. umbel: bracts lanceolate, acute, their base slightly saccate: fls. lilac, blue, or becoming purple, the throat yellow; calyx urn-shaped, green, with oval or subtriangular obtuse or rarely subacute lobes; corolla-limb $\frac{1}{2}$ in. or less across, with obovate deeply emarginate lobes: caps. subequaling or almost twice exceeding the calyx. Generally distributed in boreal and alpine regions of the northern hemisphere, in N. Amer., occurring in Maine, on Lake Superior, and in the mountains as far south as Colo. Gn. 29, p. 385; 62, p. 29; 63, p. 406 (var. *alba*); 70, p. 271; 78, p. 282. G.C. III. 40:193; 58:333 (reduced in Fig. 3191). G. 8:456. F.E. 15:674.—A widely variable species, with which Pax & Knuth unite *P. mistassinica* and others. The Rocky Mt. form has been separated by Rydberg as *P. americana*. It is difficult to find good dividing lines between the many geographical forms of this type, and one must combine

them all into *P. farinosa* or keep many of them separate as species. The above description of *P. farinosa* is the inclusive one. More narrowly defined, it may be characterized as follows: lvs. obovate-lanceolate, farinose beneath: fls. variable in color and breadth of lobes, but usually pale lilac with yellow center, umbellate; calyx oblong-ovate, with linear teeth; corolla-limb flat; corolla-lobes obovate and rounded below, distant, as long as the tube: caps. twice as long as calyx.

144. *scôtica*, Hook. The form in the extreme north of Scotland, on sandy heaths: half as large as *P. farinosa*: lvs. obovate-lanceolate: fls. bluish purple with yellow center; calyx swollen, the teeth short-ovate and blunt; corolla-limb flat, the lobes broadly obovate and about half the length of the tube: caps. scarcely exceeding the calyx.

145. *modèsta*, Biss. & Moore (*P. farinosa* subsp. *modèsta*, Pax). Treated as a subspecies of *P. farinosa* by Pax & Knuth: lvs. farinose, about $2\frac{1}{2}$ in. long and one-sixth as broad, spatulate, dentate-serrate: scape about 5 in. tall, 10-fld.: bracts setaceous: pedicels about 1 in. long; calyx campanulate. Japan. R.H.S. 39:180.

146. *davùrica*, Spreng. (*P. farinosa* subsp. *davùrica*, Pax). Small or tall, 2-12 in. or more: lvs. 1-3 in. or more long, less than $\frac{1}{2}$ in. wide, lanceolate or narrow-elliptic or narrow oblong-lanceolate, obtuse, nearly or quite devoid of farina, wing-petioled, very nearly or quite entire: fls. rose or lilac-rose, on filiform pedicels. Siberia, Mongolia, subarctic N. Amer.

147. *mistassinica*, Michx. (*P. farinosa* subsp. *mistassinica*, Pax. *P. pusilla*, Hook.). Plant small and slender, with only mere traces of mealiness if any: lvs. only $\frac{1}{2}$ in. long, stalked or not, spatulate or obovate, toothed or repand: scape about 6 in. tall, with few fls., the latter flesh-colored (rarely white) and shorter than

3190. *Primula rosea*. ($\times \frac{1}{2}$)

in *P. farinosa*. Arctic Amer., and south to N. New England, Cent. N. Y., Lake Superior, etc. B.M. 2973 (?), 3020.

148. *magellànica*, Lehm. (*P. farinosa* var. *magellànica*, Hook. f.). The south hemisphere representative, growing in S. Chile, Terra del Fuego, Patagonia: robust, 4-8 in. tall: lvs. farinose beneath, rhomb-elliptic, crenulate-denticulate: scape strong, exceeding the lvs.: fls. nearly capitate, flesh-colored or white; calyx-teeth subacute: seeds large and granulate.

149. *concinna*, Watt. Very small but very handsome species, the whole plant in the wild not more than 1 in. high and growing in cushion-like clumps: lvs. about $\frac{1}{2}$ in. long, oblanceolate, acute or obtuse, entire or crenulate, yellowish farinose beneath: scape very short, not exceeding the lvs., with a 2-5-fld. umbel: bracts short, linear-oblong: fls. rose-purple varying to white, with notched yellow corona, the corolla-tube equaling the calyx, the lobes obcordate. High Himalayas; a charming alpine. R.H.S. 39:208.

150. *cognata*, Duthie. Lvs. rosulate, $1\frac{1}{2}$ -3 in. long, obovate or spatulate, obtuse, narrowed into a winged petiole, crenate-dentate and ciliolate, farinose beneath and minutely puberulent above: scape about 9 in. high, farinose, bearing 6-12 pale violet-purple white-throated sweet-scented long-pedicelled erect or spreading fls.: bracts linear-lanceolate, ciliolate: calyx $\frac{1}{3}$ in. long, the tube prismatically angular, the lobes linear, obtuse, yellow-farinose; corolla-tube about twice exceeding calyx, the limb divided nearly to base, the lobes

3191. *Primula farinosa*. ($\times \frac{1}{2}$)

obovate or cuneate and deeply 2-lobed. Szechuan, W. China, 10,000-12,000 ft. altitude. Intro. 1906. G.C. III. 39:358. Gn. 69, p. 303.

DD. *Corolla-tube very long.*

151. *longiflora*, All. Farinose: lvs. oblong-obovate, rarely ovate, acute or obtuse, denticulate or subentire, gradually narrowed to a short, broad petiole which is scarcely distinguishable from the blade: scape stout, 4-12 in. high, rarely lower, bearing a many-fld. umbel: bracts acuminate from a broad base, frequently denticulate, base subsaccate: fls. violet, throat yellow; calyx often colored; angular, subtubular, the lobes lanceolate, acute or obtuse, very much shorter than the corolla-tube; corolla-limb about $\frac{3}{4}$ in. across; stamens always inserted on the corolla-throat: caps. cylindrical, more or less exceeding the calyx. Alps to S. E. Eu. Gt. 1878:937a. Gn. 62, p. 29. R.H.S. 39:96.

• XV. CORDIFOLIAE.

Nearly or quite glabrous, the lvs. cordate at base and distinctly petioled: corolla funnelform and caps. cylindrical: Himalaya.

152. *Gambeliæna*, Watt. The buds farinose: lvs. long-petioled, almost orbicular, about $\frac{3}{4}$ in. diam., membranaceous, base cordate, dentate; the petiole

longer than the blade: scape $4\frac{1}{2}$ in. high, exceeding the lvs., glabrous, bearing 2-7 fls.: bracts lanceolate, acute: fls. purple; calyx minutely puberulous, campanulate, split below the middle, with lanceolate acute lobes; corolla-tube broadened toward the ringless throat, the limb $\frac{3}{4}$ -1 in. across, with obcordate emarginate lobes. Sikkim-Himalaya. R.H.S. 39:192.

XVI. SREDINSKYA.

Like the *Cordifoliae*, but the corolla cylindrical: Caucasus region.

153. *grândis*, Trautv. Plant stout, tall, large-lvd., not farinose: lvs. about 6 in. long, 5 in. broad, chartaceous, wrinkled, ovate or triangular-ovate, base cordate or subcordate, irregularly twice-crenate, very lightly powdery-puberulent below; the petiole narrowly winged, exceeding the blade: scape stout, exceeding the lvs., bearing a many-fld. umbel: bracts short, lanceolate-linear, acuminate: fls. borne on filiform pendulous pedicels, pale yellow; calyx campanulate, 5-ribbed, cut one-third of length with triangular acute lobes; corolla-tube cylindrical, with erect oblong-linear, obtuse retuse lobes which have a broad sinus between them; style long-exserted: caps. cylindrical, exceeding the calyx. Caucasus. Gt. 1879:968.

XVII. TENELLÆ.

Small plants: lvs. somewhat coriaceous, narrowed to petiole: fls. 1-2 on the scape: caps. globose: Himalaya, China.

A. *Scape practically none.*

154. *muscoïdes*, Hook. f. Plant minute, densely cespitose, very glabrous, not farinose: lvs. spatulate or ovate-oblong, convex, sessile, apex subtruncate, narrowed toward the base, coarsely toothed toward the top, the broad midrib produced beyond the blade: scape none: bracts small, ovate: fls. sessile, subsolitary, 2-bracted; calyx split below the middle, cup-shaped, with triangular acute lobes; corolla-tube slender, cylindrical, the limb about $\frac{1}{4}$ in. across, with narrowly obcordate, emarginate lobes. Sikkim-Himalaya.

AA. *Scape about equaling or exceeding the lvs.*

155. *bélla*, Franch. Plant slender, cespitose, glabrous: lvs. from $\frac{1}{2}$ to about 1 in. long, including the petiole, which equals or exceeds the blade, white-farinose below, ovate or suborbicular, incise-lobed, the lobes narrow, linear, acute or mucronate, narrowed to a very narrowly winged petiole: scape exceeding the lvs., 1-2-3-fld.: bracts lanceolate, acute, entire or tridentate at the apex: fls. violet-purple; calyx open-campanulate, split to the middle, with deltoid-ovate, acute lobes sometimes tridentate at the apex; corolla-tube cylindrical, the limb densely white-hairy at the throat, $\frac{3}{4}$ -1 in. across, with obovate-cuneate lobes which are bilobulate below the middle: caps. oblong, small, included in the calyx. S. W. China. Intro. 1908. R.H.S. 39:165.

156. *yunnanénsis*, Franch. Plant rather small, glabrous: lvs. $\frac{1}{2}$ in. or less long, including the petiole, which is shorter than the blade, obovate-oblong, narrowed to the winged petiole, frequently farinose below, crenulate: scape 3-4 times longer than the lvs., bearing 1-2 fls. on pedicels about $\frac{1}{4}$ in. long ("in pairs on long slender stalks"): bracts lanceolate, acute: fls. violet-purple; calyx open-campanulate, split to the middle, with deltoid-lanceolate lobes, spreading after flowering and displaying a mealy upper surface; corolla-tube slender, the limb $\frac{3}{4}$ -1 in. across, not very concave, with deeply bilobulate lobes: caps. ovoid, small, included in the calyx. Yunnan, China. Two recent species allied to this are *P. kichanénsis*, and *P. umbrellæ*. Intro. 1908. R.H.S. 39:168.

157. *kichanensis*, Franch. (*P. Clementina*, Forr.). Plant more or less covered with farina: lvs. spatulate, sharp-serrate, obtuse or nearly so: scape slender, exceeding the lvs., bearing a spreading-drooping umbel of several almost sessile lilac-purple fls.: calyx-lobes short. W. China. Intro. 1908. R.H.S. 39:165.

158. *umbrélla*, Forr. Farinose, with short scape: lvs. oblong-pointed and irregularly dentate: fls. 5 or 6, lilac-purple, deflexed; calyx-lobes long and pointed. Yunnan, China. Intro. 1908. R.H.S. 39:168.—“The bracts radiate from the top of the scape, each one forming a channel in which a pedicel, twice the length of the bract, lies.”

XVIII. PETIOLARES.

Lvs. in rosettes, glabrous, or nearly so and mostly narrowed to their insertion, dentate, the midrib wide: fls. large, pedicelled, umbelled, the scape mostly short, sometimes long: caps. globose: Himalaya, China.

159. *petiolàris*, Wall. Glabrous, with or without farina or meal: lvs. membranaceous, rugose, polymorphous, the petiole long or short, the blade oblong or roundish in outline and more or less irregularly erose-denticulate: scape short or even none, sometimes equaling or exceeding the lvs., bearing long-pedicelled white, rose or pale purple fls.: calyx tubular or narrowly tubular-campanulate, somewhat enlarging after flowering, the lobes narrow and acute; corolla exceeding calyx, funnelliform, the limb about 1 in. across, the lobes obovate and emarginate, crenate or dentate: caps. globose, included in the dilated calyx-tube. Himalaya.—Perhaps not in cult., although *P. Winteri*, by some regarded as a form of it, is in gardens.

160. *Winteri*, W. Wats. (*P. petiolàris* var. *pulverulenta*, Hook. f.). Whole plant yellowish or whitish farinose: lvs. obovate-spatulate and irregularly dentate, 4 in. long and 2 in. broad: fls. 20 or more in a crowded umbel on a short scape, pale purple with a yellow eye and a broad white ring surrounding it; corolla-tube 1 in. long; limb flat, $1\frac{1}{4}$ in. across, the lobes rounded and toothed. Himalaya. G.C. III. 49:130; 55:238. Gn. 75, p. 130; 76:206. G.M. 54:163; 58:200. G. 33:303; 34:607; 35:207; 36:206; 37:217. R.H.S. 39:185.

XIX. CANKRIENIA.

Lvs. nearly or quite glabrous, membranaceous or paper-like, serrulate or denticulate, narrowed to the petiole: fls. in superposed umbels: caps. globose: China; also Japan, Himalaya, Java, N. Amer.

A. Fls. yellow.

161. *imperiàlis*, Jungh. Tall, stout, not farinose, the infl. excepted, glabrous: lvs. 4-16 x $2\frac{1}{2}$ -4 $\frac{1}{2}$ in., elongate-obovate or spatulate, obtuse, long-narrowed to a winged petiole which is shorter than or rarely equal to the blade, wrinkled, finely denticulate, the very broad midnerve produced beyond the blade: scape stout, much exceeding the lvs., 16-32 in. or more high, bearing several many-fl. superposed umbels which are 2-3 in. apart, more remote in fr.: bracts lanceolate from a broad base, acuminate: fls. golden yellow; calyx open-campanulate, farinose or not so, with short, broadly triangular acute lobes; corolla-tube slightly dilated toward the ringed throat, the limb about $\frac{3}{4}$ in. across, rarely less, with obovate emarginate lobes: caps. globose, included in the calyx. Mountains of Java. B.M. 7217. Gn. 40:266; 61, p. 272. G.M. 34:758, 759.—Not hardy N. The noblest of cult. primulas, the scape rising 3 $\frac{1}{2}$ ft., and bearing 5 or 6 whorls of deep yellow fls. of firm substance. Once confounded with *P. prolifera*, from which it differs, according to Hooker, in “the more robust habit, the thicker texture, broader midrib, close reticulate nervation, and bullate surface of the foliage and its deeper colored flowers.”

162. *serratifolia*, Franch. Lvs. long-elliptic or oblong, sharply irregularly serrate, rugose above, broad at the end or only short-acute: scape slender, much exceeding the lvs., bearing a few fls. on short but slender drooping pedicels; corolla pale yellow with lemon-tinted blotch in center. S. W. China.—Apparently confused in the descriptions, the *P. serratifolia* of Pax's monograph being, according to Balfour, “a chimera including *P. Beesiana*, *P. pulverulenta*, and *P. serratifolia*,” Intro. 1908. R.H.S. 39:173.

163. *Bulleyana*, Forr. Plant 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ ft. tall: lvs. paper-like, ovate-lanceolate, rounded or acute at apex, narrowed into a short winged petiole, sharply irregularly toothed, glabrous and lightly hispid above: scape tall and strong, farinose at apex, bearing 5-7 superposed umbels each 15-17-fl.: bracts linear, farinose when young: fls. faintly fragrant, deep reddish orange, in bud deep brownish crimson, on spreading or drooping pedicels that are erect after anthesis; calyx campanulate or in fr. cup-like, the lobes triangular to subulate; corolla-tube cylindrical to funnelliform, the limb nearly 1 in. across, the lobes obovate to roundish: caps. ovoid, scarcely exceeding calyx. Yunnan, China, 10,000-11,000 ft.—Named for A. K. Bulley, England, for whom Forrest collected in China. Intro. 1908. G.C. III. 46:16, 17. J.H. III. 68:103. R.H. 1911, p. 467. G.M. 52:403. G. 35:325. R.H.S. 39:172.—Produces heavy rosettes and fl.-sts. 2-2 $\frac{1}{2}$ ft. tall; a moisture-loving species, and apparently adapted to cultivation in this country.

164. *helodóxa*, Balf. f. A very recent addition to this group, collected in 1912 in China and intro. into Great Britain in 1913. It is described as a magnificent plant of strong growth, producing many whorls of dark yellow fls. Intro. 1913.

165. *Cockburniana*, Hemsl. Glabrous: lvs. membranaceous, 2-4 in. long, obovate-oblong, obtuse, the young ones more or less puberulent, soon becoming bare, obscurely lobed and at the same time minutely or obsoletely denticulate, narrowed toward the base but scarcely petiolate: scape slender, 4-18 in. high, bearing 2 superposed 3-6-fl. umbels: bracts minute: fls. yellow; calyx farinose, narrowly campanulate with deltoid acute lobes; corolla-tube cylindrical, the limb scarcely 1 in. across with obovate spreading retuse lobes. W. China. Intro. 1906. B.M. 8073. G.C. III. 37:331; 40, 231, 249. R.H.S. 39:172. Useful for pots and also planted out. *P. “Unique,”* offered by Bees, in England, is a hybrid between *P. Cockburniana* and *P. pulverulenta*. fls. cinnabar-red, in tall graceful spikes (see No. 31).

AA. Fls. white, rose, or purple.

B. Scape pilose.

166. *sonchifolia*, Franch. (*P. gratissima*, Forr.). Lvs. papery, 6-8 in. long, glabrous, sprinkled with raised dots, oblong or obovate-oblong, obtuse, double-sinuate, the mature ones subbruncate, the teeth or lobes broadly triangular and acute and spreading or somewhat reflexed, sharply denticulate: scape about equaling the lvs., thick, the top as well as the pedicels and the calyx very shortly scabrous, bearing a simple umbel: bracts very short, ovate-triangular: fls. violet; calyx mealy or not, short-campanulate, cut scarcely one-third its length, with ovate, obtuse lobes; corolla-tube broadened toward the throat, the limb $\frac{1}{2}$ -1 in. or more across, slightly concave with obovate shortly emarginate lobes: caps. globose, included in the calyx. S. W. China. G.C. III. 47:58.

BB. Scape pulverulent or farinose.

167. *pulverulenta*, Duthie. Resembles *P. japonica* in general habit, but distinguished by its silvery-farinose scape and infl. and by the deep rose-purple or violet-colored fls., also by the long and gradually

acuminate calyx-lobes: rootstock short and stout: lvs. membranaceous, 6-16 in. long including petiole, obovate or oblanceolate, rounded at apex, tapering into long winged petiole, irregularly dentate and sometimes obscurely lobed: scape to 3 ft. high, silvery farinose as are also the calyx and the spreading pedicels: bracts linear: calyx not equaling corolla-tube, white-farinose inside, the lobes lanceolate and acuminate and valvate around the elliptic-oblong or subglobose caps. after flowering; corolla about 1 in. diam., with orange-brown eye, the limb deeply divided, the lobes obcordate. W. China, 8,000-10,000 ft. altitude. Intro. 1905. G.C. III. 41:391. R.H. 1911, p. 466. R.B. 36, p. 270. Gn.W. 25:516. G. 33:609; 35:415; 37:55. G.W. 13, p. 124. R.H.S. 39:169.—Thrives in usual garden conditions but best along streams and about ponds.

BBB. *Scape glabrous, or at most only puberulent.*
c. *Corolla-throat annulate.*

168. *japónica*, Gray. Plant glabrous, tall, not mealy except the calyx: lvs. 4-6 by about 2 in., obovate-oblong or spatulate, obtuse, membranaceous, sharply and irregularly denticulate, gradually narrowed to a winged petiole shorter than the blade and with a sheathing base: scape tall, much exceeding the lvs., 8-24 in. high, bearing several many-fl. superposed umbels: bracts linear-subulate: fls. purple, rarely rose or white; calyx open-campanulate, mealy inside, with broad-triangular acuminate lobes; corolla-tube gradually broadened toward the ringed throat, the limb about $\frac{3}{4}$ in. across, with obcordate emarginate lobes: caps. globose, shorter than the calyx. Japan. B.M. 5916. G.C. III. 33:307; 40:207. J.H. III. 68:465. G.M. 48:283. G.Z. 15:129. G.W. 3, p. 183. H.F. II. 13:265. Gt. 1872, p. 195. R.H. S. 39:193. F.S. 19:1950, 1951. I.H. 18:69. Gn. 29, p. 382. R.H. 1871:570; 1895, p. 424. F.M. 1871:537, 538; 1872:9. —Blooms early in summer to midsummer. Makes a noble plant in deep moist soil and a shaded place. Hardy at the N. There are many color-forms, as var. *alba*, Hort., has white fls. (Gn. 78, p. 280. G.W. 7, p. 559); var. *rosea*, Hort., has rose-colored fls. (F.W. 1872:257); var. *lilacina*, Hort., lilac; var. *spléndens*, Hort., rich blood-red; var. *striata*, Hort., striped white; var. *salmònea*, Hort., salmon-colored; var. *bicolor*, Hort., white with crimson center; var. *carminata*, Hort., carmine.

169. *Beesiàna*, Forr. Very like *P. serratifolia* (No. 162), and at first confused with it: 1-2 ft. high: fls. rose-carmine with bright yellow eye, fragrant: lvs. oblong to obovate-oblong or ovate-lanceolate, obtuse or very short-acute at apex, narrowed to petiole which is winged above, serrate: scapes surpassing the lvs., bearing about 3 or more whorls of few to several more or less deflexed fls.: calyx campanulate, to 5 lines long; corolla-limb about $\frac{3}{4}$ in. across; spring and early summer. Yunnan, China, 9,000 ft. altitude. Named for Bees, nurseryman, Liverpool. Intro. 1908. G.C. III. 50:240, 243. J.H. III. 68:121. G. 36:175. R.H.S. 39:168.—A moisture-loving species. An attractive and promising species for cultivation.

170. *Poissonii*, Franch. Plant tall, stout, glabrous, not farinose or aromatic: lvs. about 8-9 in. long and 2 in. broad, stiff-leathery, glaucous, obovate-oblong, obtuse, sharp-dentate, margin folded upward on each side and crisped and twisted, midrib prominent; the petiole very short, sheathing and scarcely distinct from the blade: scape stout, many times longer than the lvs. (3-5 ft.), bearing superposed umbels of 3-12 fls.: bracts lanceolate, herbaceous: fls. rose; calyx split to the middle or below, tubular-campanulate, with ovate-lanceolate, subacute lobes; corolla-tube funnelform, red inside and out, puberulous inside, the limb with a golden ring at the mouth, about 1 in. across, flat on

expansion, with obcordate, emarginate and cleft lobes: caps. cylindric, little exposed above the closely investing tubular calyx, the fr.-stalks closely appressed to the scape. Yunnan, China. B.M. 7216. Gn. 62, p. 81. R.H.S. 39:169.—Fl.-stalks and calyx usually glistening and red-striate; season of bloom long. Intro. 1890. A very promising species.

171. *Wilsonii*, Dunn (*P. angustidens*, Pax, in part). Plant aromatic: lvs. green (not glaucous), tending to recurve rather than to incurve, rarely 8 in. long or more than $1\frac{1}{2}$ in. broad: fl.-stalk and calyx green, not shining: fl. much smaller than in *P. Poissonii*, the corolla-limb concave and never flat, the lobes short, rounded, crenulate, not cleft: caps. ovoid, much projecting from the cup-like calyx, the fr.-stalks not so closely appressed to the scape. China. Intro. 1907.

172. *oblanceolata*, Balf. f. (*P. angustidens*, Pax, in part). Plant like *P. Poissonii*: not aromatic: lvs. glaucous, oblanceolate or strap-shaped, always narrow (about 1 in. wide) and often more than 1 ft. long, flat, curving outward from the st., the margins with sharp and rigid small teeth: calyx not shining; corolla-limb larger than that of *P. Poissonii*, flat on expansion, tube whitish inside and outside, the lobes acute: fr. ovoid with conical summit, partially inclosed in calyx, the fr.-stalks not rigidly appressed. China.

173. *Miyabeana*, Ito & Kawak. (*P. japónica* var. *Miyabeana*, Ito). Lvs. oblong-ovate to wide-oblanceolate, acute when young but later obtuse or rounded, to 8 in. long, somewhat narrowed at base, glabrous on both surfaces, farinose beneath at first but becoming nearly or quite destitute of meal, the margin irregularly denticulate: scape 1-2 ft. high and much exceeding the lvs., bearing several superimposed, 6-10-fl. whorls, with pedicels to $1\frac{1}{2}$ in. long: bracts $\frac{1}{2}$ - $\frac{3}{4}$ in. long, narrow and acute: calyx mealy within, the lobes deltoid and shorter than the tube; corolla purple, the tube more than $\frac{1}{2}$ in. long, the obcordate lobes nearly $\frac{1}{4}$ in. long: caps. oblong or globose-oblong, inclosed in the purplish fruiting calyx. Formosa. B.M. 8606. —Closely allied to *P. Poissonii*.

cc. *Corolla-throat not annulate.*

174. *Párryi*, Gray. Plant glabrous or minutely puberulent, tall, robust, not farinose: lvs. more or less than 8 in. long, 1-2 in. broad, fleshy, narrowly obovate-oblong, obtuse or subacute and then mucronulate, entire or minutely denticulate, almost sessile, narrowed to a winged petiole which is scarcely distinguishable from the blade: scape tall, stout, 8-16 or 20 in. tall, bearing a simple 1-sided, many-fl. umbel: bracts oblong-lanceolate, acute: fls. fragrant, purplish; calyx glandular, split to the middle, the tube ovoid, with triangular acute often purplish lobes; corolla-tube broadened toward the ringless throat, the limb with a golden mouth, 1 in. across, with obcordate, emarginate lobes: caps. oblong, included in the calyx. Rocky Mts., Idaho and Colo. to Ariz. B.M. 6185. Gt. 1877, p. 65.—According to Nelson, "a handsome plant but very rank smelling; along subalpine brooks." Often 1 ft. and more high.

175. *Rúsbyi*, Greene. Not farinose (except the infl.), slender and small for the section: lvs. 2-3 in. long, oblanceolate, subobtuse, membranaceous, denticulate, narrowed to the narrow winged petiole which more or less equals the blade: scape slender, $4\frac{1}{2}$ -6 in. high, slightly exceeding the lvs., bearing a simple 6-10-fl. umbel: bracts ovate-lanceolate: fls. bright rose borne on pedicels which are soon nodding; calyx tubular-campanulate, split almost to the middle, farinose, with narrowly lanceolate, acute lobes; corolla-tube slender-cylindrical, the limb somewhat concave, almost $\frac{3}{4}$ in. across, with obcordate emarginate lobes. Mountains in New Mex. and Ariz. B.M. 7032. G.C. III. 54:190. J.H. III. 51:89. Gn. 78, p. 388.

Lvs. glabrous or nearly so, nearly coriaceous, bluntly toothed: fls. in umbels, very nearly sessile or short-pedicelled: caps. globose: Turkestan to China.

A. *Calyx cut scarcely to the middle.*

176. *vittata*, Bur. & Franch. Glabrous: lvs. membranaceous, not farinose, narrowly oblong, obtuse or subobtuse, finely denticulate, narrowed to a short winged petiole which is scarcely distinguishable from the blade or even subsessile: scape 6-10 in. high, much exceeding the lvs., white-farinose at the top, bearing a simple umbel or 2 superposed and a short distance apart: bracts lanceolate, acute, white-farinose margined: fls. somewhat nodding, purple; calyx campanulate, not split to the middle, purplish green, the lobes triangular, subacute and glabrous; corolla-tube obconical-dilated above the calyx, the limb concave about $\frac{1}{2}$ in. across, with broadly obovate, subtruncate, slightly emarginate and at the same time frequently undulate-subcrenulate lobes. Cent. China. Intro. 1905. B.M. 8586. G.C. III. 37:390; 40:209. R.H.S. 39:161.—The calyx is banded or costate with white farina.

177. *brevifolia*, Forr. Glabrous and not farinose: lvs. paper-like, very broadly ovate-elliptic, serrate, attenuate into short winged petiole: scape slender, 4-8 in. high and much exceeding the lvs., bearing a 4-12-fld. unilateral somewhat drooping umbel: bracts small, broad-lanceolate, acute: fls. faintly fragrant, pedicellate, deep blue; calyx purplish green, with broad-lanceolate acute lobes; corolla broad-funnelform, the tube equaling or exceeding the calyx, the limb $\frac{1}{2}$ to nearly $\frac{1}{2}$ in. across, lobes short and broad and emarginate. S. E. Thibet, altitude 14,500-16,000 ft. G.C. III. 57:207.

AA. *Calyx cut to the middle or beyond.*

B. *Lobes of calyx acute.*

178. *hazárica*, Duthie. Lvs. obovate or spatulate, denticulate, membranaceous, densely white-farinose below, acute or obtuse, gradually narrowed to a short winged petiole which is scarcely distinguishable from the blade: scape only slightly exceeding the lvs., about 4 in. high bearing 1 to many fls., which are umbellate: bracts linear, somewhat recurved: fls. purple; calyx narrowly campanulate, split to the middle, with lanceolate, acute, ciliate lobes; corolla-tube cylindrical, pale yellow, the limb about $\frac{1}{2}$ in. across, with broadly or narrowly orbiculate emarginate lobes: caps. included in the calyx. W. Himalaya.

179. *membranifolia*, Franch. (*P. longituba*, Forr.). Lvs. very thin-membranaceous almost diaphanous, cuneate-ovate from an entire base, unequally dentate-crenate, very glabrous, yellow-farinose below: scape scarcely equaling the lvs., bearing 4-9 fls.: bracts short, linear, these as well as the pedicels yellow-farinose: fls. violet; calyx yellow-farinose, split to the middle, tubular-campanulate, with lanceolate, acute lobes; corolla cylindrical, slender, gradually broadened to a concave limb which is $\frac{3}{4}$ -1 in. across, with orbiculate, emarginate lobes: caps. ovate, slightly exceeding the calyx. S. W. China. Intro. 1908. R.H.S. 39:165.

BB. *Lobes of calyx obtuse.*

180. *calliántha*, Franch. Lvs. with petiole 2-3 in. long, oblong or obovate-oblong, attenuate into short winged petiole, yellowish farinose beneath, dentate-crenulate: scape about twice longer than lvs., the apex and the narrow-lanceolate bracts farinose, the umbel with 5-10 pedicelled fls.: calyx brown-purple outside and farinose within, narrow-campanulate, very deeply cut and with linear-oblong obtuse lobes; corolla deep purple-violet, the tube cylindrical and little if any exceeding the calyx, the limb about 1 in. across and top-shaped, the lobes obovate and dentate. Yunnan, China. Intro. 1908.

Lvs. glabrous or nearly so, entire or nearly so, narrowed into a winged petiole: caps. cylindrical: Asia Minor to China and far north; N. Amer.

A. *Fls. yellow.*

181. *sikkiménsis*, Hook. Glabrous and devoid of farina, the calyx excepted, the scape reaching 2 ft.: lvs. 4-5 x 1-1 $\frac{1}{2}$ in., narrowly obovate-spatulate, obtuse, wrinkled, sharply double-serrate, subequally narrowed to the petiole: scape elongated, 8-14 in. high, bearing a many-fld. umbel: bracts narrow, subulate-acuminate from a broad base: fls. slightly drooping, yellow; calyx farinose, 5-ribbed, tubular-campanulate, not split to the middle, with triangular acute frequently recurved lobes; corolla-tube funnelform-broadened, the limb concave, flattened up to 1 in. across, with roundish emarginate lobes: caps. subcylindrical, exceeding the calyx. Himalayas; reported also from China, but the oriental forms may be distinct. Two of them, also in cult., are Nos. 182 and 183. B.M. 4597. Gt. 1876, p. 321. Gn. 62, pp. 82, 113; 65, p. 93; 79, p. 161. J.H. III. 49:571. G. 4:589. G.M. 52:869. J.F. 2:169. R.H.S. 39:161.—*P. sikkimensis* is a fine alpine species from altitudes of 11,000 to 15,000 ft. and more, covering large areas with fragrant light yellow bloom; considered to be easy to grow along water-courses or in other moist places, but requiring shade.

182. *pseudosikkiménsis*, Forr. Differs from *P. sikkimensis* in having shorter lvs. and larger fls.: plant 12-18 in. high, with bright canary-yellow fragrant fls. Crevices and ledges of limestone cliffs, Lichiang Range, Yunnan, 11,000-12,000 ft. altitude. Intro. 1908. R.H.S. 39:161.

183. *microdonta*, Petitm. Very like *P. sikkimensis*, but distinguished by the suborbicular-ovate glabrescent lvs. with a petiole as long as the blade, irregularly toothed: corolla at least twice as large as calyx, deep yellow and attractively veined. W. China. Intro. 1912.

184. *orbiculàris*, Hemsl. Similar in foliage to *P. Cockburniana* and *P. tangutica*, but very different in fls.; most nearly allied to *P. sikkimensis* and *P. Stuartii*, from which it differs in having nearly entire lvs., tube of corolla, which scarcely exceeds calyx, constricted near the top and below the middle at the insertion of the very short stamens, and in the limb of the corolla which is flat and with entire lobes. Lvs. somewhat coriaceous, oblong-lanceolate, 2-6 in. long, obtuse, longitudinally recurved, minutely dentate: scape about 1 ft. high, yellowish or whitish farinose, bearing an umbel of 5-7 yellow fragrant pedicellate fls.: calyx thick, campanulate, scarcely $\frac{1}{2}$ in. long, the lobes ovate and obtuse and equaling the tube; corolla scarcely exceeding calyx-tube, the limb orbicular and about 1 in. diam., the lobes orbicular. W. China. Intro. 1906. B.M. 8135. G.C. III. 39:403.

185. *Stuartii*, Wall. An exceedingly variable Himalayan species with drooping yellow fls. in a terminal umbel: radical lvs. 5-10, narrowly oblanceolate, acute, sharp-serrate or sometimes entire, yellow, mealy beneath: scape 12-18 in. tall, bearing a mealy-covered infl.: fls. light yellow, with tube twice the length of the usually acute-lobed calyx, the lobes orbicular and emarginate or sometimes orbicular and entire. B.M. 4356. G.C. II. 19:824; 25:528. Gn. 29, p. 382.—Fls. 1 in. or more long.

186. *elongata*, Watt. Glabrous: lvs. about 4 in. long, membranaceous, obovate, obtuse, crenulate, farinose or not so below, gradually narrowed to a short, winged petiole: scape almost twice as long as the lvs., 8-10 in. high, farinose above, bearing a somewhat congested umbel of 5-8 fls.: bracts triangular, acute: fls. golden yellow; calyx farinose, tubular, split to the middle, with lanceolate acute lobes; corolla-tube funnelform-broad-

ened, the limb concave, 1 in. across, with ovate, truncate, emarginate and crenulate lobes. Sikkim-Himalaya.

187. *szechuanica*, Pax. Glabrous and not farinose: lvs. 2-3 in. long, thin-membranaceous, oblong or ovate-oblong, suberose-denticulate, acute, narrowed to winged petiole: scape 8 in. or more high, stout, bearing an umbel of 6-10 yellow fls.: bracts triangular, acuminate: fls. nodding; calyx green, 5-ribbed, about $\frac{1}{2}$ in. long, tubular, incised about one-third of the way, the lobes ovate and subacute; corolla cylindrical, the limb nearly $\frac{1}{2}$ in. across, the ovate lobes reflexed. Szechuan, China.

AA. Fls. purple or violet, rarely white.

B. Corolla-lobes reflexed.

188. *Maximowiczii*, Regel. Glabrous, not farinose: lvs. distinctly petiolate or almost sessile, narrowly elliptical or elliptic-oblong, acute, densely denticulate or subentire, base entire, petiole winged, equaling the blade, sheathing, spreading at the base, whitish, rarely almost none: scape many times longer than the lvs., 8-16 in. high, glabrous, not farinose, stout, bearing a simple numerous-fld. umbel or superposed umbels: bracts long-acuminate from a broad base: fls. dark purple; calyx campanulate, green, 5-ribbed, cut one-third the length, with triangular, very acute, somewhat recurved lobes; corolla-tube slender, cylindrical, the limb flattened, $\frac{1}{2}$ in. across, with reflexed oblong lobes, neither retuse nor emarginate: caps. frequently much exceeding the calyx. N. Cent. China. Intro. 1911. B.M. 8363. G.C. III. 47:221; 53:267. Gn. 77, p. 208. R.H.S. 39:152.

189. *tangutica*, Pax. Glabrous, not farinose: lvs. almost sessile, 2-3 in. long, oblong or ovate-oblong, acute, narrowed toward the base, very entire or slightly denticulate, the very broad, white midnerve produced beyond the blade: scape stout, 14-16 in. high, glabrous, bearing superposed umbels: bracts long-acuminate from a broad base: fls. 4-6 to an umbel, soon drooping, purple; calyx glaucescent, tubular-campanulate, cut one-third its length with triangular acute ciliate lobes; corolla-limb $\frac{3}{4}$ in. across, with narrow, linear lobes. N. China. Intro. 1906. B.M. 8043. G.C. III. 38:42.

BB. Corolla-lobes not reflexed.

190. *nivalis*, Pall. Glabrous, farinose or not so: lvs. 3-5 in. long, ovate-oblong or lanceolate, obtuse or subacute, margin often recurved, crenate-dentate or subentire, gradually narrowed to a winged petiole which is shorter than and very often scarcely distinguishable from the blade: scape robust, 3-10 in. high, exceeding the lvs., bearing a many-fld. umbel, rarely 2 superposed: bracts subulate-acuminate from a broad base: fls. erect, purple or white; calyx frequently farinose, cup-shaped, split below the middle, with lanceolate, acute or rather obtuse lobes; corolla-limb $\frac{1}{2}$ - $\frac{3}{4}$ in. across, with ovate, retuse lobes: caps. frequently twice the length of the calyx. Caucasus to the Himalayas and China, northward to the Baikal and Dahuria.—A variable species, with well-marked geographical forms. The white-fld. plant in cult. as *P. nivalis* is a form of *P. hirsuta* (No. 16).

191. *purpurea*, Royle (*P. nivalis* var. *purpurea*, Regel. *P. Stuartii* var. *purpurea*, Watt). Lvs. obovate-spatulate, nearly entire: fls. purple, in compact umbels: caps. often twice length of calyx. Thibet, etc., 10,000-14,000 ft., on exposed hillsides, but seeking the shade of overhanging banks. Gn. 31:444; 62, p. 131.—Correvon describes it as a stout, strong-looking plant, with stiff upright slightly toothed lvs. (often untoothed), dark green above and bright white generally yellowish beneath, long and narrow: fls. very dark purple, numerous, drooping because of the length of the pedicel, which, with the st., is covered with white powder; corolla deeply cut: scape 8-12 in. high.

192. *turkestanica*, Regel (*P. nivalis* var. *farinosa*, Schrenk). Smaller: lvs. 2-3 in. long, and about 1 in. wide, elliptic-oblong, crenate-dentate or dentate or rarely nearly entire, densely farinose beneath and on the margins: fls. sometimes in superposed umbels; pedicels short; calyx and corolla purplish. Turkestan.

193. *sinopurpurea*, Balf. (*P. nivalis* var. *sinensis*, Pax). Said to be "a splendid species, enveloped in golden meal": robust: lvs. entire: fls. purple, on short pedicels, often in superposed umbels; calyx densely farinose inside and on margins of lobes. W. China.

194. *Purdomii*, Veitch. White-farinose: lvs. lanceolate or oblanceolate, 3-5 in. long and $\frac{3}{4}$ in. or less broad, tapering to the winged or wingless petiole: scape about 6-7 in. high, bearing a 3-12-fld. pendulous umbel of nearly sessile lilac-mauve (or bright violet) fragrant fls. with a small greenish yellow eye; corolla-tube almost closed, the limb about 1 in. across: caps. oblong, exserted. W. Kansu, China, altitude 10,000-11,000 ft. B.M. 8535. G.C. III. 53:200. Gn. 77, p. 170. G. 35:209. G.M. 56:201. R.H.S. 39:164.—Certificated by Roy. Hort. Soc., 1913. "Like most members of the *Nivalis* group of primulas, *P. Purdomii* died after flowering. It is a plant of vigorous growth and robust habit which prefers a loamy soil" (B.M.).

195. *pulchella*, Franch. Glabrous: lvs. 2-4 in. long, yellow-farinose below, narrowly lanceolate, acute or obtuse, revolute, minutely denticulate, long-narrowed toward the base: scape 8-12 in. high, stiff, bearing a many-fld. umbel: bracts lanceolate or linear: fls. erect, violet; calyx golden farinose finally bare, split below the middle, with lanceolate acute not at all rarely unequal lobes; corolla-limb $\frac{3}{4}$ in. across, with shortly lobulate, sometimes entire lobes: caps. ovate, obtuse, more or less equaling the calyx. S. W. China. Intro. 1908. G.M. 56:962. R.H.S. 39:161.

196. *pulchelloides*, Ward. A smaller plant than *P. pulchella*, with fewer and smaller fls., less depth of color and also narrower smaller lvs. China. Intro. 1911. R.H.S. 39:164.

197. *Cusickiana*, Gray. Scapes 6 in. or less tall, each bearing 2-4 violet or white fls.: lvs. oblong-spatulate or narrow-oblong, about 2 in. long, entire or very nearly so: involucre-bracts 2 or 3, conspicuous, unequal: corolla-lobes retuse, the tube little if any exceeding the green calyx-lobes which are white striate between. Early spring. E. Ore.—Offered by dealers in native plants.

198. *secundiflora*, Franch. Glabrous: lvs. 2-4 in. long, papery, golden farinose below when young, finally becoming bare, oblong or ovate-oblong, finely and evenly serrulate, acute, narrowed to a winged petiole which is scarcely distinguishable from and equaling or shorter than the blade: scape exceeding the lvs., 8 in. or more high, stout, bearing a 1-sided, 6-10-fld. umbel: bracts triangular, acuminate: pedicels soon nodding, second: fls. bright violet; calyx dark purple, marked with 5 white lines, ovate-campanulate, split to the middle, with deltoid, lanceolate, acute lobes; corolla-tube cylindrical, the limb funnelform, $\frac{3}{4}$ in. across, with broadly obovate scarcely emarginate lobes. S. W. China. Intro. 1908. G.C. III. 55:357. Gn. 78, p. 284. R.H.S. 39:160.

XXII. MACROCARPÆ.

Lvs. glabrous or nearly so, contracted into a petiole and cuneate or rounded at base, toward the apex usually toothed: caps. cylindrical or ovoid: China, Japan, N. Amer.

199. *Fauriei*, Franch. Lvs. distinctly petioled, sulfur-farinose below, $\frac{3}{4}$ -2 in. long, membranaceous, ovate or oblong-ovate, obtuse, crenulate-dentate or almost subentire, gradually narrowed to a wingless or narrowly winged petiole: scape more or less exceeding the lvs., 2-4 in. high, bearing a several- to many-fld.

umbel: bracts linear-subulate: fls. rose; calyx narrowly campanulate, split nearly to the middle, with lanceolate acute lobes; corolla-tube cylindrical, the limb flat, and about $\frac{1}{2}$ in. across, with triangular-obcordate, deeply emarginate lobes, the lobules divaricate: caps. cylindrical, much exceeding the calyx. Japan.

200. *suffrutescens*, Gray. Rhizomatous, part above ground branched and woody: plant not farinose, glabrous: lvs. about 1 in. long including the petiole, cuneate-spatulate, obtuse, leathery, top 5-7-toothed, long-narrowed toward the base to a winged petiole which is scarcely distinguishable from the blade: scape 4-5 in. high, bearing a many-fl. umbel: bracts lanceolate, acuminate: fls. reddish purple; calyx campanulate, split almost to the middle, glandular-puberulent, with lanceolate, acute lobes; corolla-tube pale, gradually broadened toward the throat, the limb $\frac{1}{8}$ - $\frac{3}{4}$ in. across, with obcordate, emarginate lobes. Calif.; alpine. R.H.S. 39:181.

L. H. B.

PRINGLEA (personal name). *Cruciferae*. Perennial herb with a long stout rhizome and forming a head of lvs., in which it resembles *Brassica oleracea*: scape thick, simple, with a strict fr.-bearing raceme: fr. a 1-celled silique. One species from Kerguelen Land. *P. antiscorbatica*, Hook. f. KERGUELEN'S LAND CABBAGE. Lvs. broadly obovate-spatulate, 3-6 in. long: peduncle arising from the rhizome, beneath the foliage, 2-3 ft. long, leafy, bearing a dense raceme 6-12 in. long: sepals oblong; petals none: fr. shortly oblong or oblong-lanceolate. R.H. 1913, p. 14. Intro. into botanic gardens abroad. Valuable as a remedy for scurvy.

PRINOS: *Ilex*.

PRINSEPIA (after Macaire-Prinsep, botanist at Geneva, Switzerland). Including *Plagiospermum Rosaceae*, subfamily *Prinseeae*. Woody plants, chiefly grown for their early-appearing flowers and bright green dense foliage.

Deciduous shrubs: branches with axillary spines: pith lamellate: lvs. alternate, petioled, entire or serrulate; stipules small, lanceolate: fls. 1-4 in the axils of last year's branches or in axillary racemes; calyx with cup-shaped tube and broad and short lobes imbricate in bud; petals 5, spreading, suborbicular, clawed; stamens 10 or many, with short filaments; ovary superior, 1-celled, the style inserted near the base, with capitate stigma; ovules 2: fr. a drupe with a smooth or slightly fissured stone.—Three species on the Himalayas and in N. E. Asia to N. W. China. The edible frs. are gathered in their native countries.

The two prinsepias in cultivation are low spiny slender-branched shrubs with narrow bright green foliage and white or yellow flowers appearing with the leaves in early spring along the branches of the previous year and followed by purple or black cherry-like drupes which, however, so far have been produced only sparingly in cultivation; possibly the flowers, though apparently perfect, are functionally dioecious or they need insects for fertilization, which are wanting at the very early flowering time of this shrub. The shrubs have proved perfectly hardy at the Arnold Arboretum, only the flowers suffer sometimes during cold weather; they are among the earliest shrubs to burst into leaf and are conspicuous by their bright green foliage when most other shrubs are still bare. They seem to grow best in a sunny and open position and in well-drained soil. Propagation is by seeds sown after maturity or stratified and sown in spring or by greenwood cuttings under glass; also by layers.

sinensis, Oliver (*Plagiospermum sinense*, Oliver). Fig. 3192. Shrub, to 6 ft. or taller, nearly glabrous: younger branches light gray, older brown, with short axillary spines about $\frac{1}{4}$ in. long: lvs. slender-petioled, ovate-lanceolate to lanceolate, long-acuminate, cuneate

at the base, sometimes broadly so, entire or sometimes sparingly serrulate, finely ciliate, otherwise glabrous, bright green above, paler beneath, 2-3 in. long: fls. 1-4, on pedicels about $\frac{1}{2}$ in. long, bright yellow, $\frac{1}{2}$ - $\frac{3}{4}$ in. across; sepals triangular ovate; stamens 10: fr. subglobose or ovoid, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, purple, juicy; stone ovoid, compressed, rugose. April, May. N. E. Asia. M. D. 1903:1. I.T. 5:182. H.I. 16:1526. R.H. 1907, pp. 418, 419.—Besides being an ornamental shrub this species may be worth while growing for its cherry-like edible frs. which have a pleasant acid taste.

3192. *Prinsepia sinensis*. ($\times \frac{1}{2}$)

cicled fls. with only 10 stamens, while *P. utilis* has the fls. in axillary racemes and many stamens.

P. utilis, Royle. Shrub, to 5 ft.: spines 1-1 $\frac{1}{2}$ in. long, usually leafy: lvs. elliptic to oblong-lanceolate, acuminate, entire or serrulate, 1 $\frac{1}{2}$ -4 in. long: fls. pedicelled, in axillary racemes, white, about $\frac{1}{2}$ in. across: fr. purple, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, edible. Himalayas.—Apparently not in cult. in this country and probably not hardy north of Washington, D. C.

ALFRED REENDER.

PRIONIUM (Greek *saw*, referring to the leaves, which have serrate edges). *Juncaceae*. Tender aquatics growing in great masses in running water.

Stem erect, woody, from a repent rhizome: perianth rigid, cleft to the base, segms. ovate, subequal; stamens 6; ovary sessile, globose, 3-celled; ovules usually few, often 2 in a cell: caps. rigid, 3-valved; seeds usually only 1 to a cell.—One species in S. Afr. This is one of the few plants of the rush family having the lvs. crowded at the top of an erect woody st. 5-6 ft. high. This plant may be grown in a pot placed in a pan of water, and, if desired, may be planted out for the summer in a wet position. Prop. by division.

Palmita, E. Mey. St. stout, often forked, 2-4 in. in thickness, reaching a length of 5-6 ft.: lvs. linear, rigid, glabrous, 3-4 ft. long, in a dense rosette at summit of st.: infl. a large, dense, terminal panicle on long peduncle; perianth and bracts $\frac{1}{2}$ in. long. B.M. 5722. G.W. 11, p. 390. F. TRACY HUBBARD.†

PRITCHARDIA (W. T. Pritchard, British consul at Fiji in 1860). *Palmaceae*, tribe *Corypheae*. Spineless fan palms from islands of the South Pacific; also in Cuba if *Colpothrinax* is included.

Trunk usually ringed, crowned at the summit by a large cluster of spreading plicate-flabelliform lvs.: spadix at first erect, ultimately drooping at the fruiting stage: fls. hermaphrodite, small, green; ovary 3-cornered or 3-lobed, narrowed into a strong style; corolla with persistent tube and deciduous segms.; embryo subbasilar.—About 14 or 15 species; by some, Washing-

tonia is included in this genus. The genus was monographed by Beccari in *Malesia*, vol. 3 (1890). A good horticultural account is that of Wm. Watson in *G.C. III.* 13:332 (1893). True pritchardias, according to Watson, differ from all other fan-lvd. palms in the form of the blade, which is cuneate in outline; the lvs. are also exceptionally soft and pliant. The best of the genus, probably, is *P. pacifica*, which is remarkable for its fibrous fluffy lf-stalks.

3193. *Pritchardia pacifica*.

(*P. macrocarpa*, Lind.). Trunk 20 ft. high, 1 ft. thick, usually much lower in cult.: lvs. roundish, 3-4 ft. long, covered beneath with pale brown matted wool, slit for about 1 ft. into about 60 segms.; petioles 2-3 ft. long, without spines: calyx glabrous and not prominently striate: fr. ovoid, $\frac{3}{4}$ in. long, yellowish red. Hawaiian Isls. I.H. 26:352.

BBB. Fr. greenish, globose, 15-20 lines thick.

Mártii, Wendl. Trunk generally not exceeding 5-6 ft., but recorded to 12 ft., as thick as in *P. Gaudichaudii*: lvs. glabrous and glaucous below, not woolly; segms. about 40, not as deep; petioles longer: calyx densely striate: fr. globose, $1\frac{1}{4}$ - $1\frac{3}{4}$ in. diam., greenish. Hawaiian Isls.—Cult. in S. Calif.

AA. Ovary of distinct carpels. (*Colpothrinax*.)

Wrightii, Becc. (*Colpothrinax Wrightii*, Wendl.). BARREL or BOTTLE PALM. PALMA BARRIGONA. Fig. 3194; also Fig. 2725, p. 2437. Formerly retained in *Colpothrinax*, as the only species, but recently (1907) transferred to *Pritchardia* by Beccari: st. single, rising for 3-6 ft. or more, at first cylindrical but gradually increasing in thickness in a bottle-like or flask-like form, the trunk slender and ascending beyond this part till the whole reaches 30-40 ft.: lvs. circular in outline, more than 5 ft. across, suborbicular, flabellate-radiate, regularly divided into about 80 segms. about $4\frac{1}{4}$ ft. long; segms. rigid, slightly leathery, pale green, very glabrous and shining: spadix simply duplicate-branched; spathe 2, slightly leathery, red-brown: fls. sessile: fr. globose, 1-celled. Sandy savannas in Pinar del Rio, Cuba.—A very striking palm is indicated in Fig. 3194, which is drawn from photo-illustration in *Pomona College Journ. Ec. Bot.*, vol. 3.

P. borneensis, Hort., was intro. in 1891 by Linden, but unknown to botanists.—*P. filamentosa*, Hort., is presumably a catalogue error for *P. filifera*.—*P. filifera*, Lind., is *Washingtonia filifera*.—*P. grandis*, Bull., is *Licuala grandis*.—*P. periculorum*,

Wendl., is characterized by its dark brownish golden petioles and obliquely spherical fr. Pomotu Isl.—*P. robusta*, Hort., listed abroad, is without botanical description.—*P. Thirstonii*, Drude, is distinguished by its long slender fl.-stalks like fishing-rods bearing a thyrses-like infl. Neither of the last two is in cult. in Amer.

L. H. B.†

PRIVET: *Ligustrum*. P., Mock: *Phillyrea*.

PROBOSCIDEA: *Martynia*.

PROCHNYANTHES (Greek, *kneeling and flower*; referring to the sudden bend in the flower which is likened to a knee). *Amaryllidaceæ*. Interesting tuber-bearing plants, probably suitable for cult. in pots and also planted out: closely related to *Polianthes* and *Bravoa*, differing chiefly in the shape of the flowers.

Sts. slender, from oblong tubers which crown short thick rootstock: lvs. mostly basal: infl. a lax spike or raceme: fls. always in pairs, tubular below, abruptly bent at the middle, bell-shaped above; stamens 6, included: fr. 3-celled, many-seeded.—A genus, discovered by E. Palmer in 1886, of which two species have been described. Native of W. Mex.

viridescens, Wats. Sts. 4-6 ft. high: lvs. mostly basal, numerous, 1-2 ft. long, 2-3 in. broad, erect: fls. 5-30 pairs, brownish; pedicels nearly wanting to $1\frac{1}{2}$ in. long. At first supposed to be a very rare species, known only from near Guadalajara, Mex., but found by the writer to be very common in the mountains of the states of Jalisco, Durango, and Zacatecas. Not yet in the trade, but it is a plant that deserves to be intro.

P. Bulliána, Baker. Hardly differs from the above but described as having larger fls., which are sessile instead of having a long pedicel: fls. brownish green. The fls. are not jointed at the pedicel as Baker says. B.M. 7427.—*P. viridiflora*, mentioned under B.M. 7427, is a mere slip of the pen for *P. viridescens*.

J. N. ROSE.

PROMENÆA (named presumably after the prophetess of Dodona). *Orchidaceæ*. A group of small herbs with the habit of *odontoglossum* but having leaves of paler green.

Leaves conduplicate in the bud: pseudobulbs evident: infl. originating above the annual leafy axis, 1-2-fld.; sepals and petals subequal, spreading, the lateral sepals forming a mentum with base of the column; labellum movably joined to the base of the column.—About 10 species in Brazil. It is one of the many genera formerly united with *Zygopetalum*. For cult., see *Zygopetalum*.

xánthina, Lindl. (*Zygopetalum xánthinum*, Reichb. *P. citrina*, Donn). A little orchid with small ovate pseudobulbs and lanceolate lvs. 2-3 in. long: fls. pale lemon-yellow; labellum

3194. *Pritchardia* (or *Colpothrinax*) *Wrightii*, from Cuba. Swelling is usually higher on trunk.

3-lobed, with crimson spots in the throat; column streaked with red. June. Brazil. G.W. 14, p. 521.

graminea, Lindl. Lvs. about 6 in. long, lanceolate, faintly striate, jointed to the equitant bases: scapes 3-5, clustered; fls. dirty yellow, spotted with brown; sepals and petals oblong-lanceolate; labellum oval, crisp and toothed on the margin, shaded with rose and blotched with crimson-brown. Spring. Brazil. B.M. 5046. G.C. II. 23:636.—On account of the absence of pseudobulbs this species is now generally placed in the genus *Keffersteinia*.

stapelioides, Lindl. Pseudobulbs 4-angled, 1-2-lyd.: lvs. lanceolate, pale glaucous, reticulate; peduncle 2-fld.; fls. green outside, yellowish inside, speckled and banded purple. Brazil. B.R. 25:17 (as *Maxillaria*).

P. micröptera, Reichb. f. Fls. $1\frac{1}{2}$ in. broad; sepals and petals lanceolate, acute, light green; lip 3-lobed, basal half white with narrow purple bars, front lobe green; column pale green. Brazil. —*P. Rollissonii*, Lindl. Fls. pale yellow, the lip with purple spots; sepals and petals very acute; lip with lateral lobes ovate, acute, the front lobe oblong, apiculate. Brazil. G. 12:237; 17:103.

HEINRICH HASSELBRING.

GEORGE V. NASH.†

PROPAGATION: *Cuttings, Grafting, Layers, Nursery, Seeds, and Seedage.*

PROSÁRTEs: *Disporum.*

PROSÖPIS (Greek, but the meaning is obscure). *Leguminosæ*. Tender trees and shrubs, including the mesquit and the screw bean, two forage plants of considerable value in the arid regions of southern California and the Southwest.

Stems with or without spines, the spines axillary, solitary or in pairs or only the stipules spinescent: lvs. bipinnate, 1 or 2 pairs of pinnæ; lfts. usually numerous, small, entire: fls. small, greenish, in cylindrical or globose axillary spikes: pods linear, coriaceous and indehiscent.—About 25 species, tropical and subtropical regions of the world.

The mesquits are thorny shrubs which ordinarily grow only a few feet high in the desert, but under favorable circumstances make trees 60 feet high. They are also called algaroba and cashaw. The sweetish pods are eaten chiefly by cattle. Seeds and plants are offered in southern California.

A. Plant spiny: pod straight or sickle-shaped.

juliflora, DC., and allies. MESQUIT, or MESQUITE. Several forms have been confused under this name. *P. juliflora*, DC., is a strictly W. Indian species, with many pairs of lfts. very close together, $\frac{1}{4}$ – $\frac{3}{4}$ x $\frac{1}{2}$ – $\frac{1}{3}$ in. rather thin in texture and elliptic to oblong, apex and base blunt and rounded. *P. dulcis*, Kunth, is a Mexican species somewhat similar to the preceding but with the lfts. slightly more distant although still crowded, $\frac{1}{4}$ – $\frac{1}{2}$ x $\frac{1}{4}$ in., linear to linear-oblong, apex tending to be acutish and mucronulate, the texture more coriaceous. *P. glandulosa*, Torr., is the common species throughout Texas, New Mex., and S. Calif., also occurring in Mex.; it has more remote pairs of lfts. often distantly so, $\frac{3}{4}$ –2 x $\frac{1}{8}$ – $\frac{1}{4}$ in., which, when mature, are longer than in *P. juliflora*, rigid and linear, those of the young shoots frequently elliptical to spatulate and up to $\frac{1}{4}$ in. or even more broad, base slightly narrowed, apex mucronulate and usually acutish although also bluntish. *P. velutina*, Wooton, is a southwestern species which looks much like *P. dulcis*, but the younger shoots, lvs., and lf.-rachis velutinous-pubescent; lfts. $\frac{1}{4}$ – $\frac{1}{2}$ x $\frac{1}{8}$ – $\frac{1}{4}$ in. oblong, apex rounded, base rounded. Ariz. and S. Calif.

AA. Plant less spiny: pod spirally twisted.

pubescens, Benth. (*Strombocarpa pubescens*, Gray). SCREW BEAN. TORNILLO. Shrub or small tree, merely spinescent on petioles: lfts. 5-8 pairs, oblong, $\frac{1}{4}$ – $\frac{1}{2}$ in.

long: spikes globose to cylindrical, $1\frac{1}{2}$ –2 in. long: pod twisted, nearly sessile, 1-2 in. long. Texas, Calif., Mex. —The pods are used as food by Mexicans and Indians.

P. strombulifera, Benth. (*Acacia strombulifera*, Willd.), is a shrub 5-8 ft. high, with ash-gray bark, very short spines, lfts. of the pinnæ 4-6-paired, linear, and the pod yellowish, about 2 in. long, and spirally twisted. Peru.

F. TRACY HUBBARD.†

PROSTANTHÈRA (Greek, to add to, and anther; referring to the connectives of the anthers being spurred or crested beneath). *Labiata*. Shrubs or subshrubs with resinous glands, and commonly strong-scented.

False whorls 2-fld., axillary or borne in a terminal raceme; fls. often white or red; calyx campanulate, limb 2-lipped; corolla-tube short, dilated into a broad campanulate throat; limb 2-lipped; stamens 4, in pairs; anthers 2-celled, connective dorsally slightly prominent, often spurred or appendaged: nutlets obovoid and netted wrinkly.—About 40 species from Austral. Prop. by cuttings of young shoots.

nivea, A. Cunn. A beautiful shrub, 3-6 ft. high, glabrous except the corolla or with a few appressed hairs: st. and branches slender, twiggy, upper ones 4-angled: lvs. $\frac{1}{2}$ – $1\frac{1}{2}$ in. long, oblong-lanceolate or linear, entire, pale green; margins involute, especially on older lvs..

3195. *Protea cynaroides*. (X $\frac{1}{6}$)

fls. snow-white or tinged with blue; pedicels short; calyx about $\frac{1}{4}$ in. long, green; corolla $\frac{1}{2}$ – $\frac{3}{4}$ in. across. Rocky hills, New S. Wales and Victoria. B.M. 5658.—Can be safely grown only where the lemon is hardy. It is a showy species when well grown.

Other species which have been intro. and sometimes cult. abroad are: *P. denticulata*, R. Br. Robust shrub: lvs. sessile or nearly so, broadly lanceolate to narrow-linear, with rigid bristles on the margins: fls. in distant pairs forming interrupted terminal racemes, lilac to purple. B.M. 7934.—*P. pulchella*, Skan. Subshrub about $1\frac{1}{2}$ ft. high, slender: lvs. subsessile, linear to linear-lanceolate: fls. with a lilac subrotate corolla, the tube white at base, dotted with dark purple at the throat. B.M. 8379.—*P. rotundifolia*, R. Br. Shrub, 3-7 ft. high: lvs. broadly ovate, orbicular or spatulate, entire or coarse crenulate: fls. in short close terminal racemes, purple. G.M. 58:147.

F. TRACY HUBBARD.†

PRÔTEA (from Proteus, the sea-god, who changed into many forms; alluding to the baffling diversity of the species). *Proteaceæ*. Tender shrubs, small trees or acaulescent perennial plants, which are among the most attractive and characteristic plants of the Cape of Good Hope, a region whose plant life is singular.

Leaves alternate, coriaceous, entire: fls. in many-fld. sessile or subsessile, terminal or lateral, usually solitary heads, inclosed in an involucre of numerous imbricate coriaceous to scabrous and various colored bracts; ovary covered with long hairs; ovule 1: nut

densely bearded.—About 100 species, mainly from S. Afr. but extending into Trop. Afr. Their fl.-heads are said to look like a "glorified artichoke." Indeed *P. cynaroides* (Fig. 3195) is named from this very resemblance. (*Cynaroides* means cynara-like; and *Cynara* is the artichoke.) It has bright pink fl.-heads which last several months. The structure of the fl.-heads is the distinctive feature of the whole family of the Proteaceæ. The showy parts of the fl.-head are the bracts, which are often rigid, colored, and overlap one another like the scales of a hard cone or an artichoke. "When the heads of *P. cynaroides* first open," says Watson, "they are full of honey and are known to the Boers as honey-pots." This honey is collected and made into a kind of sugar. The blooming of the "honey-pots" is a great occasion for picnics. Watson saw large bushes of *P. speciosa* at the Cape, which he declared were quite as effective as big specimen rhododendrons. "Fifty years ago," writes Watson, in 1891, "there were about 30 species of Protea included among popular greenhouse plants in England; now one may safely say there is not one, the few really under cultivation being only in botanical collections." In 1881, Hooker wrote: "That these and many other plants requiring like treatment will be reintroduced, and will be the wonders of the shows for many successive seasons, is as certain as that they were once the glories of the old flue-heated houses that our forefathers called stoves, in which orchids quickly perished, and Banksias and Proteas threw magnificently." Over 40 colored plates of proteas have been published, of which 23 appeared in Andrews' Bot. Rep. between 1797 and 1811.

The interest in proteaceous plants is growing in southern California. Proteads have a reputation for being difficult to cultivate away from the Cape, but Hooker's statement seems to indicate that their culture is not so much difficult as special. Under glass they are said to require a coolhouse which is airy and sunny. "The one great danger to cultivated Proteads," says Watson, "is excessive watering, and to guard against this it is found to be a good plan, in the case of delicate species, to place the pot in which the plant is growing inside a larger one, filling up the space between with silver sand. The latter is always kept moist." It is suggested by one grower that it is possibly not excessive watering that injures them, but insufficient drainage. Many of the species need staking, as the shoots are quick to break off at the base if unsupported. Proteas ripen seeds freely, and seeds can be easily procured from the Cape.

cynaroides, Linn. Fig. 3195. Bush, up to 6 ft. high or sometimes acaulescent: lvs. petioled, varying from subrotundate and obtuse to elliptic and acute: head sessile; outer involucre bracts ovate to ovate-lanceolate, inner lanceolate, oblong, acuminate, tomentose, exceeding the fls.; ovary oblong, covered with long whitish hairs. S. Afr. G.F. 8:35. G.C. III. 17:773. G.M. 38:407.

mellifera, Thunb. A large bush, 6-8 ft. high: lvs. linear-oblongate: involucre bracts very viscid, those of the stipes silky pubescent, the others glabrous, dark red to whitish green with pinkish tips and margins but usually rosy pink: fls. whitish, exceeded by the involucre; ovary covered with long golden hairs. S. Afr. B.M. 346. R.H. 1903:308.—The oldest specific name for this plant is *P. repens*, Linn. Mant., not Thunb., but following Phillips & Stapf in Fl. Cap. 5 sect. 1:577, the name *mellifera* is maintained. They state that "The specific name *repens* is so inapplicable to this plant, while Thunberg's name is so suitable and has been in such general use that we have retained it." Var. *rùbra*, Hort., is a form of *P. mellifera* which has been offered in the trade abroad.

nana, Thunb. (*P. rosacea*, Linn.). Smooth shrub, 2 ft. high, branched: lvs. acicular, erect-spreading, acute

or acuminate: involucre scales oblong, obtuse, the outer greenish, the inner scarlet, exceeding the yellowish fls. S. Afr. B.M. 7095. G.F. 4:413. G.M. 35:268, 269. Good horticultural accounts of proteas are those of Wm. Watson in G.F. 8:34 and 4:412, which have been liberally quoted above.

WILHELM MILLER.

F. TRACY HUBBARD.†

PROTECTION, as used by the gardener, is an indefinite term. A plant may need protection from living agencies, as animals, birds, insects, or plants (including fungi and weeds), or it may need protection from the weather,—heat, cold, rain, drought. Generally, however, the gardener means winter-protection, which again covers two very distinct ideas,—freezing injury and mere mechanical injury. Most Cape bulbs, for example, are ruined if they are frozen; tulips are not. Yet Cape bulbs may sometimes be wintered outdoors if they are protected by a covering heavy enough to keep out frost. Strawberries, on the contrary, are covered after frost with a light mulch, which is designed merely to keep the plants from being heaved by alternate freezing and thawing. These are the main objects of winter protection in the East, at least with herbs. In the prairie states the fruit-trees also need protection from the hot drying winds of summer and from sunscald, which are not the important considerations with eastern fruit-growers. See *Winter Protection*. Allied topics are discussed under *Greenhouse*, *Coldframes*, and *Hotbeds*; *Diseases and Insects*; *Weeds*; *Transplanting*.

PRÔTIUM (probably the Javan name). *Burséracæ*. Trees, with balsam sap: lvs. toward the ends of the branches, alternate, 3-foliate or uneven pinnate; lfts. few-paired, rather large, petiolulate, entire or dentate; panicles long-peduncled, fasciculate, branched: fls. small, slender-pedicelled; calyx small, cup-shaped, 4-6-cleft or -dentate; petals 4-6, linear-oblong; disk urn-shaped; stamens 8-12; ovary sessile, 2-4-celled: drupe fleshy, globose.—About 50 species, mostly natives of Trop. S. Amer., some species also in India, Malaya, Mauritius, Madagascar, W. Indies, and Mex. *P. ser-ratum*, Engl. (*Burséra serrata*, Wall.). Sometimes planted in tropics and subtropics for ornament, and wood said to be used for furniture: evergreen: lfts. about 7 or more, opposite, narrow-ovate, base acuminate, pubescent or nearly glabrous, serrulate or entire: panicles axillary, lax, much branched, shorter than the lvs.: fls. very small, hermaphrodite, pubescent externally; calyx 5-toothed; petals 5; stamens 10: drupe globose, 1-3-celled. India.

PROTOPLASM. The living or organized cell-content. The difference between living and non-living things, so far as it has been possible to study it, consists in the fact that the former are characterized by the possession of protoplasm, "the physical basis of life." This protoplasm is a most complex material, the seat of diverse chemical reactions and physical changes, and at the same time a material having a wonderful capacity for correlation and growth. When the cell or living organism is killed, there is no loss of substance, and the material originally constituting this protoplasm remains, but there is left relatively little to suggest living protoplasm. So far as is known, this non-living residue can never be reëndowed or activated with those characteristic properties of correlation and growth, and many other properties less complex, which are the potential or kinetic possessions of the living. It is in some ways unfortunate to call the dead material by the same name as the living.

In the living plant or animal, the protoplasmic unit is the cell, usually microscopic in size, and an association of cells of the same form, or with similar functions, constitutes a tissue. The spores of many fungi and of mosses and ferns are single cells. In plants the protoplasmic unit is usually surrounded by a resistant mem-

brane, or cell-wall, resulting in a high degree of rigidity and strength. In some cases, as in "woody" tissues, the cells become highly modified, the walls may be much thickened, and the protoplasm may disappear, leaving only the non-living cell-walls.

Since the protoplasm is the seat of the greater part of the chemical reactions and physical changes even in the more complex living plants, with it must be associated the absorption, digestion, and assimilation of foods, respiration, and excretion, as well as growth, reproduction, and heredity capacities. In the simplest plants, such as many of the lower algæ (pond-scums), consisting of but a single cell, this cell must perform all the functions of the organism; but in complex plants there is a certain amount of differentiation of labor or function of the various protoplasts, or cell units. Thus the various tissues are more or less seats of different physiological processes; for example, the nectar-glands are "organs" of excretion, the green tissues are the seats of organic food-making (see *Photosynthesis*).

The protoplasm of the cell is itself differentiated into various structures, important among which are (1) the cytoplasm, or general protoplasm, within which are (2) the nucleus, and (3) the plastids (in green plants).

there were in California 91,470 acres of bearing prune trees in 1915, and 24,774 acres of young trees. This places the prune next to the peach, which is the leading deciduous tree-fruit of California with a total acreage of 144,888. The annual cured prune product of California, during the decade 1905 to 1914, has ranged from 57,000,000 pounds in 1908 to 205,000,000 pounds in 1912, the average annual product being 122,050,000 pounds. The Pacific Coast States produce all the prunes grown in the United States, and, according to the United States Census of 1910, "California reported, in 1909, 85.7 per cent of the total value of dried prunes produced in the United States." The development of this American product has not only reduced importation of European prunes so that they no longer receive distinctive enumeration in the customs reports, but about half the product is annually exported.

There are several reasons why the prune product of California is so overwhelmingly large and is still increasing. Beyond the general suitability of natural conditions for fruit-growing, there is, in the case of plum varieties, the total absence of the curculio, and "black-knot;" the practical freedom from rot-fungi which attack ripening fruits, and a dry condition of

soil-surface and air during August and September which favor gathering fruits from the ground and curing in the open air. Curing in evaporators by artificial heat is practically unknown. The process of handling prunes, from the tree to the package, is outlined by an experienced handler, E. N. Richmond, of San José, as follows:

"Prunes should never be picked from the tree. They should be allowed thoroughly to ripen and fall to the ground. An orchard should be covered by pickers every seven to ten days—seven days preferably, so as to prevent sunburn of the fruit lying on the ground. The usual form of contract with pickers calls for four pickings, no shaking of the trees until the third picking, and then at grower's discretion.

"The green fruit is hauled to the dipper-shed in picking-boxes and there passed through a light solution of lye. A kettle or tank, holding 200 gallons of water and containing a basket container, is used for this purpose. In many instances the fruit is rinsed by passing from this dip into a vat of clear water and then dumped onto a combination pricking-board and grader, operated by power, which grades the fruit into three grades so that the drying in the field can be uniform. The fruit is then placed on trays 8 by 3 feet and taken to the drying-yard and dried in the sun. The purpose of passing the fruit through the lye-solution and over the pricking-board is that the skin may be slightly cut, thereby hastening evaporation, preventing fermentation and producing a fruit with a clear bright meat. From the dipper-shed to the dry-yard, the fruit is hauled on a one-horse truck especially constructed for this purpose.

"The operation of drying requires judgment. Fruit should be allowed to lie in the sun on the trays until about three-quarters dried, and then the trays are stacked in piles, one above the other, leaving air-vents on either end. About twenty trays can be stacked in one pile and the finishing process takes place in this stack. Under normal weather conditions it takes from ten days to two weeks to cure prunes. While the fruit is on the trays in the dry-yard, it should receive at least one turning by hand, shaking the trays or using brooms, so that the fruit secures an equal drying on all sides. It also materially lessens the time of drying and makes a finer grade of fruit. The fruit must not be taken from the trays until it is thoroughly cured.

"At the packing-house the fruit is carefully separated

Protoplasm is generally regarded as a viscid semi-fluid material, and commonly it behaves as a liquid (an emulsion colloid). When killed, protoplasm is "set," that is, it becomes a jelly-like matrix, and it is a study of such fixed material upon which have been based the earlier views regarding structure. There is strong evidence that much of what is called the finer structure of protoplasm is a result of fixation, and that there is actually little real "structure" in the living material, although certainly the gross appearance may change more or less with the diverse activities of the cell. Protoplasm cannot be expressed chemically; indeed, the view which is today most widely accepted is that it consists of numerous substances physically related, rather than of complex molecules of a definite "substance."

PRUMNÓPITYS: *Podocarpus*.

PRUNE (from *Prunus*), is used in this country to designate a cured dried plum, and also the varieties that are employed for the making of this product. In literature, however, it may be used rather indefinitely for many kinds of plums, particularly those that are firm-fleshed; "dried prunes" is then used for the cured product which in this country is known only as "prunes." The product is now an important article of horticulture and commerce in California and the Pacific Northwest. It is also produced in southern and to some extent in central Europe.

Prunes in California.

There are at least three important characters which distinguish the prune interest of California from that of any other state, viz.: the extent of the industry, the method of curing, and the plum variety chiefly used.

According to figures gathered by George P. Weldon,

into the different grades, varying from thirty to forty prunes to the pound, up to prunes running smaller than 120 to the pound. The grades as to weight and size are obtained by passing the fruit over a large grader which consists of a series of screens of different sizes, commencing with the smaller size and increasing to just a trifle larger size every 3 or 4 feet. There are from eight to nine different screens, the largest fruit passing over the end. As the fruit comes from the grader, it is carefully tested by weighing and counting, and taken to the proper bin. From there it is taken as required for packing to the processor or cleanser. The fruit in the field has been subjected to considerable dust and dirt as well as insect life. The processor or cleanser conveys the fruit through a long vat of boiling-hot water, thoroughly washing and cleansing it. From the processor the fruit is dumped on a long shaker which further assists in the cleansing process, so that by the time the fruit is put into the boxes it is in a most sanitary condition. Prunes are packed in packages varying from one pound to fifty-five pounds according to the requirements of the trade for which they are intended."

The third distinctive feature of California prune-growing is the predominance of the Prune d'Agen—the variety which has been chiefly used in the commercial prune industry of France from early times. This variety (which is discussed in the article on *Plum*) has the "prune character" developed to a degree which no other plum variety has thus far attained. It has a sweetness often reaching above 50 per cent of fruit-sugars in the cured fruit, but this is not its distinctive character. The really distinctive characters are: (1) the high aromatic flavor in the cured fruit; (2) the dense fine texture of the flesh, which gives this variety unequaled tenderness and mouthful quality, both as a confection and as a slightly cooked fruit; and (3) the smallness, thinness and smoothness of the pit, which the tongue gratefully accepts. The chief objection to the variety is that, when grown without thinning and the tree is allowed to carry too much bearing wood, the fruit will be small. For this reason there has been a demand for the last fifty years for a prune retaining all the characters of the Prune d'Agen and adding greater size. Although continued effort has been made to find such a prune elsewhere in the world and to originate such a one in this state, this end has not yet been reached. All rivals of the predominant variety are, when dried, either flat or acid in flavor, coarse and stringy in flesh and large and rough in pit. It is quite probable that California growers are repeating the experience of the early French growers who have given us the Prune d'Agen as the result of their prolonged selection. Leonard Coates, of Morgan Hill, has emphasized the fact that there are variations toward better size among established trees of the true characters of the Prune d'Agen and propagation from such variations is being pursued. In view of long experience of disappointment in importation and origination, this seems at present the most promising avenue toward gaining size without losing other characters. The varieties which have been brought to notice as substitutes for the French prune have been planted only on a small acreage, have sold well for size and style and may continue to be profitable, although they can never satisfy habitual prune-eaters, for the reasons stated.

The culture of the prune tree as pursued in California has already been outlined in the article on the plum.

E. J. WICKSON.

Prunes in the Pacific Northwest.

Prune-culture in the Pacific Northwest has had a very checkered career. The early pomologist took much interest in plums and prunes, because of the magnificence of the products secured, and the ease with which they were grown. This interest increased

up to the early nineties, when the prune reached a boom period. Thousands of acres were planted in a few years. They were planted on all soils and exposures and a great many varieties were tried. Toward the latter part of the nineties, there was a tremendous production of the fruit, mostly of a questionable value. Few men knew how to evaporate prunes properly. Much of the product decayed in transit, while other portions were evaporated so hard as to be practically inedible. There was little or no market for the dried tart prune; consequently, there was but one inevitable result: namely, a collapse, and in a few years thousands of acres of trees were taken out. The United States Census shows that there were nearly a million less prune trees in the state of Oregon in 1910 than were growing in 1900. About 1905 the industry began to pick up. Those growers who had good locations and proper varieties, and who had mastered the process of evaporation, began to find a market. This market has steadily improved, until in the last seven or eight years the prune has proved to be a very profitable crop, either shipped green, or evaporated. The increase in acreage in the past four years has been very large, and the industry now seems to be thoroughly established. The United States Census for 1910, giving the number of plum and prune trees, shows the following figures:

Oregon.....	1,764,896
Washington	823,082
Idaho.....	302,855

The number of bushels produced is as follows:

Oregon.....	1,747,587
Washington	1,032,077
Idaho.....	179,027

There are two distinct areas in which the prunes of the Northwest are produced. In western Oregon and Washington, prunes are grown entirely for evaporation, the conditions there being strong loamy soils and abundant rainfall. East of the mountains the prunes are grown very largely in the irrigated valleys, although some of the dry-farming areas are producing a splendid fruit. The product at present, however, is largely centralized in such valleys as the Boise and Payette valleys of Idaho, the Grande Ronde and Freewater districts of Oregon, and the Walla Walla and Yakima valleys of Washington. In these districts the prunes are rarely evaporated, but are shipped out in the fresh condition to eastern markets, where they are generally known as plums.

There is considerable controversy, especially in the western section, as to the better locations for prunes. Some growers prefer the bottom lands—either the sandy loams along the rivers, or the stronger clay soils. The contention is that these lower elevations produce larger prunes and a greater yield. Another set of growers, however, stoutly maintain that the rolling hills are the only places for prunes, and while their plums are smaller, nevertheless they are heavier and sweeter, and their orchards are more reliable. East of the mountains, the prunes are generally planted in the silt loams.

Since all plum trees blossom in early spring, they are very subject to loss from frosts and cold rains. To offset the loss from frosts, the southern and eastern exposures should be avoided, as these are undesirable since the thawing out on such exposures is very rapid, supposed to lead to a breakdown of the tissues.

When planted on the lighter loams, the peach root is preferred, but when on the stronger loams, plum roots are better. As yet, not enough investigation has been conducted to determine what species of plum roots are the most desirable for the various locations.

On the lighter soils, or higher elevations, the trees are planted from 18 to 20 feet apart, but when grown on the stronger loams, from 20 to 22 feet should be allowed.

Some growers think that on extremely rich soils, 25 feet is a more desirable distance.

The tillage given prunes is very similar to that for other deciduous fruits grown in the Northwest. In all young orchards, the tillage should be very thorough in the early spring. With trees not in bearing, tillage should cease by the middle of July. In many of the bearing orchards, where the tillage has been very thorough in the early spring months, sufficient vigor of tree and size of fruit is often obtained so that tillage may be discontinued by the middle of July or the first of August, but in many of the orchards it will be necessary to continue the tillage up to about the time of harvest, which comes later, varying from the first of August to the middle of September.

Formerly, the trees were all headed from 30 to 40 inches in height. In more recent years, however, many growers are heading from 20 to 24 inches and producing very satisfactory trees. The same general principles that apply to the pruning of apple trees, also apply to the prune. Care should be taken to have the main scaffold limbs spaced as far apart as possible. Strong heading back is necessary the first few years. With many orchards, summer pruning can be conducted advantageously, the pruning being done largely in June and consisting of a cutting back of the terminals to the point where it is desirable to force out new laterals. Occasionally a little thinning out of the laterals is practised. When the trees reach their heavy bearing, which is about the seventh year, it is desirable to give them moderate pruning annually, the aim being to keep the trees well supplied with strong one- and two-year-old wood, as the large plums are found almost invariably on the vigorous wood. When orchards have been allowed to run down somewhat, it is often found desirable to thin out the spurs with hand shears, and in this way reinvigorate the remaining spurs. When trees are very much run down, the most satisfactory treatment will probably be to dehorn them, forcing out a new vigorous top which, in three to four years, will produce commercial crops of fruit. Very little hand-thinning is done with plums and prunes in the Pacific Northwest. The Italian prunes generally thin themselves. Some varieties of plums, however, must have hand-thinning.

Very little work has been done as yet with manures or fertilizers. Commercial fertilizers, where tried, have never given striking results in the older orchards. The growers are finding that, in mature orchards, a stable compost is very desirable. When it is impossible to secure such material, vetch or rye planted the latter part of August or early September, and plowed under in the early spring, is very beneficial. Care has to be taken, however, not to use excessive amounts of nitrogen, as this element tends to make the trees unproductive, and generally makes the skin of the prune so heavy that it is difficult to evaporate.

The prune industry in the Pacific Northwest is not old enough as yet to demonstrate how long an orchard will remain profitable. However, there are several orchards in Oregon forty years old, that are still very productive. On the other hand, there are orchards twenty years of age that have passed their usefulness. The trees in this latter class, however, have been neglected. Where good soil is obtained, and proper care given, it is safe to say that the orchards will be productive at least fifty years.

There are a number of insects which are troublesome to the prune. The San José scale attacks the tree, but is very easily controlled with the lime-sulfur spray. The borers—both the peach-root (*Sanninoidea opalescens*) and the shot-hole (*Xyleborus dispar*)—are very bad.

Young trees are often severely attacked with aphids. Other insects which are more or less troublesome at times are the leaf syneta (*Syneta albida*), the Indian meal moth (*Plodia interpunctella*), the rose-leaf hopper (*Empoia rosæ*), and the tipulid (*Ctenophora angustipennis*). Of the other diseases, the mushroom root-rot (*Armillaria mellea*) is very serious, especially when the trees have been planted on newly cleared land. Brown-rot (*Sclerotinia fructigena*) is the worst pest of the fruit and is becoming more serious. Other diseases that have to be contended with are crown-gall, rust, and bacterial canker. The latter three diseases, however, are not nearly so serious as the first two mentioned.

Of the varieties of prunes that are grown in Oregon, the Italian (Fellenberg) comprises about seven-eighths of the planting, and the percentage in favor of the Italian is constantly increasing. For evaporation, it is the only one worth consideration in the Northwest. For shipping purposes, however, numerous plantings have been made of the Tragedy, and also of the Hungarian. Other varieties that are grown to a limited extent are the French, locally called the Petite, or Prune d'Agen, the Pacific, Willamette, Clairac Mammoth, Columbia, Tennant, Silver, and Sugar. There is, of course, to be found scattered over the Northwest a

3197. A prune orchard in Oregon, with the fruit on the ground ready for harvest.

miscellaneous list of soft plums that are grown largely as local fruit. Since the Italian prune is benefited by growing with other varieties, there will probably always be a scattering of other kinds planted in our orchards. Many growers report that, wherever the Italians are near other varieties, a more satisfactory set of fruit is obtained on the Italian. In the evaporated fruit districts, the Petite will be the pollinator. The greatest drawback of this prune is its small size. It, however, dries heavier than the Italian and, size for size, sells somewhat higher.

When prunes are to be shipped in their green state for eating fresh in the eastern markets, it is customary to pick the fruit while it is still very hard and green. The plums, however, will have developed to a very large extent their true color before the packing is undertaken. The fruits are graded carefully and packed in five-pound baskets, four baskets being placed in a crate. While this crate virtually holds about twenty pounds, the weight of the fruit will range from eighteen to thirty pounds, according to varieties, size, and the general condition of the fruit. These four-basket carriers are the typical ones used for plums, apricots, and vinifera grapes constantly seen in the eastern markets. The fruit, when properly refrigerated, has not only been shipped all over the United States, but successful shipments have also been made to Europe, Mexico,

and Alaska. When the fruit is to be evaporated, it is first allowed to ripen on the trees and should not be gathered until it drops naturally to the ground (Fig. 3197), or will drop with very little shaking. The fruit is picked from the ground in bushel boxes, the pickers going through the orchard every few days to gather it up. The yield varies tremendously, from 1,000 to 8,000 pounds to the acre. As soon as the fruit is gathered, it should be hauled to the evaporators and evaporated quickly in order to avoid brown-rot, which often spreads rapidly in the containers.

There are two main types of evaporators used for drying fruit,—steam and hot air. The steam driers are used only where a very large output is obtained. It is customary for most of the orchardists to dry their own fruit. Since the orchards on the whole are rather small, an inexpensive building is used for the process, and the hot-air type of building is erected. These hot-air driers are of two distinct types, the tunnel, and the stack. There are many forms of tunnel driers. These tunnels consist of groups of long nearly horizontal pipeways, built over a fire pit. They vary in length from 25 to 50 feet. Each tunnel in itself may

are also provided. These should be in below the vent pipes so as to furnish fresh air rather than to assist in rapidly sucking out the warm air. There is a very close relation between ventilation, air-circulation, and the humidity of the atmosphere. Such relationship, unfortunately, has not been well studied by the larger number of those operating the evaporators.

The temperature is gradually increased during the drying process, starting in the neighborhood of 125° to 135° and finishing at 160° to 180°. It requires about thirty-six hours on the average to dry prunes well, the time depending on the building, ripeness of the fruit, and atmospheric conditions. The fruit will generally produce about twenty pounds of dried fruit to a bushel of fresh. Before the prunes are placed over the heat, it is customary to wash and grade the fruit. The more modern buildings now have automatic machinery which does all of this labor in one process. The prunes, after being sorted, are dipped into boiling lye. This is generally at the strength of one pound of lye to thirty to fifty gallons of water. This use of lye is adopted solely for the purpose of checking the skin of the fruit so that the gases can escape more readily and the prune

	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	------	-----	------	-----

done, but very little is now practised in the Pacific Northwest.

The finished product is subject to considerable loss from fermentation, mold, and the attack of mites. It will be necessary for considerable scientific investigation to be made before the problems connected with these losses will be entirely understood. As soon as the prunes have been processed, they are taken in the hot, warm condition and packed in boxes. These boxes range in capacity from ten to fifty pounds. The bottom of the box is faced. Uniform, well-proportioned prunes are flattened with the fingers. This makes a very attractive top for the box when it is reversed. Lace paper and lithographs are used on the better packs.

In selling prunes, they are bought entirely according to weight, but based on the number of prunes to the pound: such as 30-40's, 40-50's, and so on, indicating the number of prunes to the pound. The table on page 2816 illustrates the method used in basing the prices for any given size of prune in the Pacific States.

The figures below the words "bulk basis," such as 30 to 35, 70 to 75, mean the number of prunes in a pound of fruit. The figures to the right of the words, "bulk basis," such as 2, $2\frac{1}{8}$, refer to the so-called base price paid for prunes. The base price is, in this case, figured on the sizes running from 75 to 80 prunes to the pound. Note that the figures to the right of 75 to 80 are the same as the figures to the right of the words "bulk basis."

As an illustration of the way the table works, take the first figure to the right of the words "bulk basis," which is 2. That means then, that for prunes running from 75 to 80 to the pound, the buyer will pay 2 cents a pound. Should the prunes be so large, however, as to run 30 to 35 to the pound, note that the figure to the right of this number is $4\frac{1}{4}$. Should they run, for example, 55 to 60 to the pound, note that the figure opposite is 3.

Should the base price at any time be more than 5 cents, one could easily enlarge this table by adding $2\frac{1}{4}$ cents to the base price for prunes running from 30 to 35 to the pound, and decrease the price $\frac{1}{4}$ cent for each smaller size in proportion to the size of the prunes.

C. I. LEWIS.

PRUNÉLLA: *Brunella*.

PRUNING is the methodical removal of parts of a plant with the object to improve it in some respect for the purposes of the cultivator. Much of the current "pruning" is really repairing, and is now commonly called "tree surgery." See page 354, Vol. I.

Under this denomination are comprised a multitude of practices and ideals. It is impossible to give any advice for pruning until one has analyzed the subject and knows the objects for which one is to work and the underlying principles on which the practices must rest. The larger part of the writing on pruning gives mere advice or directions, or details some person's experience, without analyzing or clarifying the subject. The practice must differ with every person and every condition, but the principles are general. The ideas that are associated with pruning may be grouped around three centers: (1) pruning proper, or the removal of a part of a plant for the purpose of bettering the product and improving the character of the remaining part; (2) training, or the disposition or placing of the individual branches, a practice that ordinarily is coincident with pruning proper; (3) trimming, or the shaping of a plant into some definite or arbitrary form.

The principles that underlie pruning proper may be associated with two purposes,—the lessening of the struggle for existence amongst the parts of a plant, and the cutting away of certain parts for the purpose of producing some definite effect in the formation of fruit-buds or leaf-buds or in modifying the habit of the plant.

There are more branches in the top of any plant than can persist; therefore there is struggle for existence. Those which have the advantage of position persist. Nature prunes. Dying and dead branches in any neglected tree-top are illustrations of this fact. Whenever the struggle for existence is greatly lessened, the remaining branches receive a greater proportion of the plant's energy, and they therefore make stronger growth, yield better produce, or are more productive in flowers and fruit. Pruning is essentially a thinning process.

There exist the widest variations of opinion as to the merits of pruning, particularly as it applies to fruit-trees. Some persons oppose any pruning whatever. Undoubtedly a certain type of novice places too high estimate on pruning, as if it were the one essential operation; others carry the practice to needless extremes; but the reasons for pruning lie in the nature of the plant, and the useful results are attested by long experience. It is one of the cardinal practices in the growing of many kinds of plants, along with tilling,

fertilizing, combating pests and diseases; and it is not to be considered as a thing apart or as a remedy or corrective for all deficiencies.

In itself pruning is not a devitalizing process; it is devitalizing only when it is carried to excess or when the wounds do not heal and disease sets in. It is rather an invigorating process, since it allows more nourishment to be distributed to the remaining parts of the plant. The notion that pruning is devitalizing arises from false analogy with animals, which suffer shock or injury when parts are removed. The fact that pruning is not a devitalizing process is proved by every tree. The tree is a record of successive prunings. Note the number of branches on the seedling tree in the nursery-row or in the forest, and then consider that all these branches, with the exception of the leader itself, will probably perish in

3198. More limbs have perished than have survived.—Nature's pruning.

the course of time. The forest tree develops a bole and the side limbs are pruned away by natural causes. (Fig. 3198.)

Knots are records of this natural pruning. In the greater number of cases the limbs die and are removed when still very young, and they leave small record in the grain of the wood; but all visible knots are histories of the removal of large branches. As a rule, it is only when the knots become knot-holes that injury results. A knot-hole means decay, and this decay may extend into the heart of the tree, finally causing it to become hollow. A discolored or decayed heart is an indication of disease. The disease originates on the outside of the plant; it is the result of inoculation. This inoculation takes place through some bruised or broken part; it is usually an infection of filamentous fungi. These fungi gain a foothold in the dead and dying cells of the wound, and as they grow they are able to destroy the living cells. The larger the wound, the greater is the liability to infection. It is very important, therefore, in the pruning of trees, that the wounds shall be as small as possible and shall heal quickly. This means that the best pruning is that which is practised annually, so that the branches to be removed do not attain to large size. This annual pruning is also most desirable for other reasons, as will be seen

Pruning when transplanting.

Woody plants should always be pruned when they are transplanted. This is because the roots are pruned in the very process of removal, and the tops should be reduced in proportion. For some time after the plant is transplanted, it has very little vital connection with the

soil, and if all the top is allowed to remain there is much evaporation from it and a dissipation of the energies. How much of the top shall be removed depends on how much of the roots was removed in digging, on climate, and also on personal desires of the operator. It is a general practice to cut back the top of a plant at least one-half on transplanting; in some cases still more of the top is removed. In broad-leaved evergreens, some of the leaves may be cut in two at transplanting, to reduce transpiration. (Fig. 3199, after Wester.)

Quite another question is the particular form in which the top shall be left. Some growers prefer to remove all side branches, if it is a fruit-tree, and leave a straight whip. (Fig. 3200.) They are then free to start the new branches where they like. This is allowable with very young trees, and it is much employed with peach trees, inas-

Pruning fruit-trees.

Fruit-trees are pruned for the purpose of enabling them to produce a superior quality of fruit. In America, they usually are not pruned primarily to make them assume any definite or preconceived shape. It is best, as a rule, to allow each variety of tree to take its own natural or normal form, pruning it only sufficiently, so far as shape is concerned, to remove any unusual or unsymmetrical growths.

1. The fundamental conception in the pruning of fruit-trees is to reduce the struggle for existence, so that the remaining parts may yield larger and finer products.

2. The result of pruning fruit-trees should be to keep the tree in bearing condition, not to force it into such condition. If the tree has received proper care from the time it is planted, it should come into bearing when it reaches the age of natural fruitfulness. Pruning aids to keep the tree in proper bearing condition. When trees have been much neglected, pruning may be the means of reinvigorating them and setting them into a thrifter condition. In such cases it is one of the means of renovating the tree, as are tilling, fertilizing, and spraying.

3. Heavy pruning of the top in any year tends to produce very vigorous growth on remaining parts. This is because the same amount of root energy is concentrated into a smaller extent of top, thereby causing a heavier growth. This is particularly true if the pruning is performed when the plant is dormant.

4. Heavy pruning of the root tends to lessen the production of wood, because the same amount of top receives a less supply of soil-water.

5. Trees that grow much to wood are likely to be relatively unproductive. It is an old maxim that checking growth induces fruitfulness, so long as the plant remains healthy. This, of course, does not mean that trees of decreased vigor are more fruitful, nor that the maintenance of full growth from the first is to be avoided. Orchards that are kept in a vigorous thrifty condition are most productive, other things being equal; but when very thrifty trees do not bear, the checking of the growth may induce the desired results. If the tree is thrown into redundant growth every two or three years by very heavy pruning, it tends to continue to produce shoots at the expense of fruit. When a tree is to be brought into bearing condition by general

good treatment, the aim should be to keep it in that condition by a relatively light annual pruning. Violent pruning is allowable only when trees have been

3199. Pruning or cutting back of orange at time of transplanting.

planted when the top is only of one season's growth. (Fig. 2792, page 2496.) If trees are two or three years old and well branched, as is the case with apples and pears, most persons prefer to leave three or four of the main branches to form the starting point of the future top. (Fig. 3201.) These branches may be headed back half or more of their length. Some years ago a method of very severe pruning came into notice under the name of the Stringfellow or stub-root system, taking its name from the late H. M. Stringfellow, of Texas (page 1598, Vol. III), who wrote much concerning it. The fullest presentation of Stringfellow's ideas will be found in his book, "The New Horticulture." It advises that practically all the roots be cut away and that the top be shortened to a straight stick 1 or 2 feet long, without side branches. It is the supposition that when trees are reduced to their lowest terms in this way, the new root-branches that arise will take a more natural form and the tree will assume more of the root character of a seedling. This method of transplanting has not gained acceptance.

In most cases, it will be better, particularly in trees that are three years or more old, to prune them only moderately, shortening them in all around, allowing a part of the original root-system and a part of the top to remain.

Whatever the way of pruning at transplanting, good live buds should be left on the tree; the practice of pruning two-year-old wood to a whip is therefore to be discouraged, for only dormant buds (if any) then remain on it.

3200. Pruning peach tree at time of transplanting.

3201. Pruning of a young tree on transplanting.

neglected and it is necessary to bring them back into bearing condition by renewal or to re-shape them.

6. The operator should know where the fruit-buds are borne before undertaking the pruning of any fruit-tree; otherwise he may destroy too many of them. If he knows the position of the fruit-buds, he may prune in such way as to thin the fruit even without the removal of much wood, and thereby to reduce the struggle for existence to a minimum. Every species of tree has its own method of fruit-bearing. The pear bears its fruit largely on old spurs. The peach bears mostly on the long wood of the last season's growth, particularly when trees are young. If one is to thin the fruit of the pear by pruning, therefore, it is necessary to remove part of the spurs. In the peach it is necessary to cut out or to cut back a part of the previous year's growth. Each species of plant is a law unto itself in these regards.

7. Heading-in under certain conditions (which the operator must judge by observation) tends to promote fruitfulness. If the heading-in is very severe it may amount to a heavy pruning, and in that case it may

set the plant into shoot-bearing rather than into fruit-bearing. It is not to be supposed that heading-in is necessarily to be advised in order to make trees bear. They may bear just as well if they are never headed-in, provided they are otherwise well pruned and well cared for. Whether one shall head-in the fruit-trees or not, is in part a personal question. If the trees are growing too rapidly, it is well to head them back. This may be necessary when trees are growing on very fertile soil in order to keep them within bounds; but the heading-in under these conditions may not conduce to greater fruitfulness. When trees are planted too close together, it may also be necessary in order to prevent the plantation from becoming too thick. Some growers like a low-headed and rounded top; this is a question of personal preference and of the general management of the plantation. If the orchardist desires such form, it is necessary to head-in the tree. It should be remembered that the more a tree is headed-in the thicker it tends to become in the crown and the more inside pruning is necessary. Whenever there is danger of fruit-rot, as in plums and early peaches, it is a question whether the thick form of top is the most advisable.

8. Pinching-in the annual growths in early summer tends to augment the development of fruit-buds, although these buds may not be

developed the very year in which the pinching-in is performed. This is a special practice, however, which can be employed only on small areas and with particular trees. It is essentially a garden practice and not an orchard practice. In the orchard, one must depend for fruitfulness on the general good care of the plantation, and in this care pruning is one of the essential factors.

9. Pruning fruit-trees usually resolves itself into a thorough and systematic thinning out of the weak, imperfect and interfering branches. Thereby, the energy of the plant is saved and is deflected to those parts that are capable of bearing a useful product. The sun and air are admitted. The tree becomes manageable for spraying and for picking. All the fruits have an opportunity to develop. How much or how little to thin, is a special question. In humid climates, much thinning may be necessary. In dry hot climates, as on the Plains, but little thinning is allowable, else the branches may sunscald. Figs. 3202 and 3203 illustrate two pruning ideals.

10. Scraping the rough bark from old trunks may be a desirable practice, since it destroys the breeding places of insects and fungi. Trees that have been continuously thrifty, however—that have received uniformly good tillage, fertilizing, pruning, spraying—rarely need to be scraped, as the bark remains relatively smooth and firm. Only the loose outer bark should be removed. On ornamental trees, the bark is a part of the characteristic beauty, and it should not be scraped. Although not a pruning question, this is closely associated with pruning practices.

Pruning ornamental plants.

Ornamental trees and shrubs are pruned for three purposes: (1) to enable them to produce greater quantity of bloom; (2) to make them take some desired form; (3) to remove unusual or injured growths.

The pruning of woody plants for the production of flowers is controlled largely by the flower-bearing habit of the plant. Most early-blooming plants develop their flower-buds the year before. Heavy pruning, therefore, particularly heading-in, when the plants are dormant, cuts off the flower-buds and the amount of bloom is lessened. If these plants are pruned just after the flowers are passed in spring, the best results will be secured, since the new growths will then develop flower-buds for the year following. Among spring-flowering

3202. Young apple tree, the marks showing which limbs may be removed to advantage.

3203. A New York cherry-grower's ideal of a Montmorency cherry tree. Perhaps the large branch on the front side should have been removed when the tree was young.

3204. Cordon training. An apple tree (grafted on dwarf stock) trained in two branches on a horizontal wire running only 2 feet above the ground. Each year the growths are cut back to spurs.

shrubs that may be pruned after flowering (while in leaf), are deutzias, diervillas or weigelas, forsythias, lilacs, flowering almond, wistaria, exochorda, and many spireas and viburnums. It may be advisable, however, to prune such plants in winter for the purpose of thinning them, thereby allowing the flower-buds that

3205. Pear trees trained on a wall. When once the wall is covered, the tree is never allowed to increase in surface area. It is cut back to spurs each year, much as grape-vines may be treated.

remain to produce larger bloom. In most ornamental plants, however, it is the number of flowers rather than the size of each which is desired.

Plants that bloom late in the season, as hydrangea and most species of clematis, make their flower-buds on shoots which arise that very season. With such plants, it is well to prune rather heavily while they are dormant in order to cause them to throw up a profusion of strong shoots in the spring. These shoots will bear that summer. Among the summer-flowering shrubs that may best be pruned when dormant, are hydrangeas, althea or hibiscus, ligustrums, trumpet creeper, ceanothus, potentillas, vitex, symphoricarpos, and many kinds of clematis, lonicera, jasminum, and some spireas.

Pruning to make the plant assume some definite form is essentially a method of shearing or heading-in. If it is desired to have a very regular and definite shape, it is well to shear the plant at least two or three times a year in order to keep down the exuberant growths. It is a common practice to shear the plants only in the winter, but if this shearing is somewhat violent, as is usually the case, the plant throws up numerous strong shoots very early in spring and it remains shapeless during a large part of the growing season. Except in very special cases and for formal landscape work, it is much better to let shrubs and trees assume their natural and characteristic forms: these forms, in fact, constitute the beauty of the species.

Training.

There is relatively little careful training of plants in North America, largely because of the expense of the skilled labor necessary to perform it. Land is also relatively cheap, and room can be given for the natural development of most plants. In many parts of the Old World, fruit-plants must be grown in very small areas, and it may be necessary to train them on walls, sides of buildings, or on trellises of various kinds. Trained fruit-trees may generally be referred to one of three categories: the wall tree, which is trained against a continuous surface; the espalier, which is trained on a trellis, the branches starting at nearly right angles from a central shaft; the cordon, or training to a single or double strand near the ground. Properly, an espalier

is a trellis (page 1146), but the word is commonly used for the plant that is trained on the trellis. There are many variations in the methods of training and pruning in each of these three classes, and the methods are such as can scarcely be well elucidated in writing. The Old-World literature is replete with instructions. In recent American literature, the fullest account is to be found in "The Pruning-Manual." In order that trees may be well trained on walls, espaliers, and cordons, it is necessary that the training be begun in the nursery. The Old-World nurseries grow plants that are trained for various uses, but the American nurseries do not. If, therefore, the American is to train trees in any of these formal shapes, he should secure specimens that are not more than one year from the bud or graft, and begin the training himself. The illustrations (Figs. 3204-3206) suggest some of the special methods of training fruit-trees. On such trees, if skilfully trained and carried out in patient detail, the best excellence in individual fruits may be attained.

Pruning after frost-injury.

When woody plants have been much injured by freezing, it is the best practice to remove all dead parts as soon as the line of demarcation is evident.

The kind of corrective pruning to be employed when trees have been much shattered by winter cold is a subject that needs further investigation. It is not a single or a simple problem, as much depends on the previous state of the trees and on other conditions. Speaking of peach trees, Chandler writes (Research Bulletin No. 8, Missouri Experiment Station): "Pruning the trees severely following a winter when the wood has been killed, although apparently in the best condition of maturity, seems to reduce the amount of killing. However, such pruning following winters when the wood has been killed on account of its not having reached the proper condition of maturity in the fall, generally due to the presence of wet weather following a drought the season before, is liable to result in greater loss than if no pruning were done."

On the proper practice to pursue in the case of frozen citrus trees, T. F. Hunt issued the following advice

3206. Apple tree trained on an espalier.

to California growers following the freeze of January, 1913: "Relative to badly injured trees, it appears best not to prune until the new growth has started. It is best to delay the pruning until a distinct line of demarcation develops between the injured and uninjured wood. At the Citrus Experiment Station last year five-year-old lemon trees were frosted. Good results were obtained by waiting until the new growth had reached from 4 to 5 inches in length; in that instance about six weeks were required. Allowing the injured limbs to remain not only makes it possible to determine how much it is best to prune, but the limbs and leaves afford shade to the bark of the tree, which is accustomed to protection.

3207. A proper cut.—The healing tissue arises from the side of the wound, not from the hard wood.

3208. A well-covered wound. The pruning was properly performed, no stub being left.

It may be desirable, in some instances, to spray the trunks and limbs of large and severely pruned trees with whitewash in order to reflect the sun's rays. Wrapping the trunks of young trees with loose sun protectors would seem extremely desirable.

"It seems reasonably certain that no injury to the tree can result from any of the materials passing from the frozen oranges into the tree. An examination of those oranges which have been too badly frozen to be fit for shipment shows that most of them only partially have been killed; consequently, they are presumably respiring carbon dioxide. This loss of energy would be saved if the oranges were removed from the tree. There is no experimental evidence, however, to show whether this loss is sufficient to warrant the cost of early removal by hand."

When to prune.

It will be gleaned from the above discussion that the time of pruning depends on many circumstances, and chiefly on the result which it is desired to reach. So far as the healing of the wound is concerned, it is

perhaps best to prune when the vegetative activities begin in spring so that the wound is quickly covered or "healed." For the purpose of checking growth and

producing other definite results, it may be necessary to prune at other times of the year. As a general rule, however, the best time to prune

is in late autumn to early spring, when labor can be had and before the rush of spring work comes on. In practice, it resolves itself largely into a question of the convenience of the operator.

The wound.

The wound made by severing a branch heals by means of a callus which forms from the growing tissue between the bark and wood. (Fig. 3207.) This tissue rolls over the wound, finally joining in the center and completely covering the old wood. The old wood itself takes no part in the healing process; in fact, it dies. When the healing is complete, the old wood is merely covered and preserved from external injury and infection, much as fruit in a jar is preserved by being protected with a tight cover. There is no dressing that will hasten the healing process except as it keeps the wood from decay. In other words, the whole object of dressing a wound is to protect it. The dressing hinders bacteria and fungi from securing a foothold and thereby prevents the rot. Wounds that are exposed for some years nearly always become unsound at the center because of the intrusion of these organisms, and even if the wounds should subsequently heal over, the infection may still extend down the heart of the tree and finally cause its death. The best covering for a wound

is one that protects it best from weather, microbes, and fungi and which persists the longest. Ordinarily, good white lead paint, applied heavily and renewed occasionally, is a good pro-

3209. The stub is longer than necessary, although the fault is not a serious one. It will heal well if the old wood is kept healthy.

3210. Common fault in pruning. This wound cannot heal until the stub rots away, and by that time the tree may be irreparably diseased.

tection for fruit trees. Grafting-wax may afford a fair protection, if it is applied warm and thin so that it soaks into the tissue. If it is merely spread over the surface, it soon blisters and becomes loose and affords relatively little protection. For shade and forest trees, which are treated by "tree surgeons," special dressings and disinfectants are employed.

The rapidity with which wounds heal depends very largely on their position on the tree and the way in which they are made. Wounds along the main branches, which are the leading avenues for distribution of food, heal more speedily than those on the weaker side branches. If the wound is close to the branch it may be expected to heal better. (Figs. 3208, 3209.) If a stub is left several inches long (Fig. 3210), it seldom heals until it rots back to the main branch or trunk; and by that time the decayed part may have extended deep into the tissue of the tree. It is a common notion that a limb should be cut at right angles to the direction of the limb itself and beyond the bulge at its base. It is a better plan, however, to make the wound parallel to the direction of the branch or trunk that remains, and closer to it. This wound may have a somewhat larger superficial area, but it is much nearer the source of the healing food-supply.

3211. Improper way of applying pruning-shears.

Tools.

A good large-bladed large-handled sharp knife, a narrow and pointed rather fine-toothed saw, and a pair of shears are the essential pruning tools. Many forms of these three primary implements are on the market.

3212.
A good ladder for pruning or picking.

In tools that require such incessant use, when the work is in progress, and that meet such resisting obstacles, only the best makes and materials should be secured. The operator must learn by practice how to use them, for even in such simple implements as these there is a right way and a wrong way. Fig. 3211 (from Wester), for example, shows an improper way of using shears, cutting at such a long acute angle rather than crosswise or merely oblique as to render the work difficult, leave a long sharp stub, and injure the shears. A good ladder is also necessary for large trees. When the top or head of the tree is low enough, the pointed ladder shown in Fig. 3212 (from Wester, a bamboo ladder used in the Philippines) is one of the best types; it is easily inserted among the branches and it may be rested securely in a crotch. Many other pruning implements are useful for special work, and suggestions of these will be found in various bulletins and in the catalogues of dealers. See also the discussion in Vol. IV, page 1950. L. H. B.

PRUNUS (ancient Latin name of plum). *Rosaceæ*. THE STONE-FRUIT, as PLUM, CHERRY, PEACH, NECTARINE, APRICOT, ALMOND. Pink-flowered and white-flowered shrubs and trees of wide distribution, grown for fruit, and also for ornamental foliage and flowers.

All woody plants: lvs. alternate, simple, usually serrate and more or less gland-bearing: fls. mostly in spring, sometimes preceding the leaves, either solitary or in clusters, perfect, the pistil single (more than 1 in abnormal forms) in a cupule or cup (usually designated the calyx-tube), the stamens numerous and perigynous, the petals and calyx-lobes 5: fr. a drupe, usually 1-seeded by the abortion of one of the 2 ovules. (Fig. 3213.)—The species are probably 175, mostly in the North Temperate zone, although a number of species are native in the Andean parts of S. Amer.

The genus as here outlined includes several well-marked groups, some of which are regarded as distinct genera by many authors. In their extreme or typical forms, these subgenera are very distinct, but the group as a whole is well defined and nothing is contributed to clear definition by raising the groups into generic rank, and it is an advantage for easy reference to have all forms treated in one place rather than to scatter them under several different names. A marked group is *Padus*, with flowers in true racemes; and its ally, *Laurocerasus*, is also fairly well distinguished.

Horticulturally, *Prunus* is one of the most interesting of all genera. It includes important orchard fruits,—peaches, plums, cherries, apricots, and almonds. It is also prolific of ornamental subjects, as double-flowered, variegated-leaved, colored-leaved and weeping forms. Most of the cultivated species are hardy in the latitude of Philadelphia and many are hardy in Ontario. All are of easy culture. Nearly all the species are spring-flowering. Only *P. Cerasus* var. *semperflorens*, amongst the commoner kinds, blooms as late as midsummer. They are very useful for spring gardens, therefore, where they make great display, but their short season of bloom and the very ordinary foliage of most of them have limited the planting of the ornamental kinds. All members of the genus are easily grown.

Some of the ornamental species are not grown on their own roots, but are worked on stocks that can be

grown easily and cheaply and of which seeds can be secured in abundance. The commonest stocks for the ornamental kinds are the plum (*P. domestica*), peach, and sweet cherry. On the plum are grown the dwarf almonds and the double-flowering and fancy-foliage plums. The Myrobalan plum (*P. cerasifera*) is sometimes used for the same purpose. Peach stocks may be used for the same species, as a rule; and they are also employed, particularly in the South, for many fruit-bearing plums. The sweet cherry (*P. avium*) is a good stock for the various kinds of double-flowered, weeping and fancy-leaved cherries. It is an important point in the growing of these grafted prunuses to remove all sprouts from the stock as soon as they appear. This is particularly true of the dwarf almonds, since the stocks are usually stronger-growing species and tend to sucker from the root.

In North America there has been a remarkable contemporaneous evolution of fruit-bearing plums from the native species. Several hundred orchard varieties have been described, and the trees are grown commercially over a wide range of country in the South, in the Mississippi Valley and on the Plains,—in regions in which the common *Prunus domestica* does not thrive. An interesting group of pubescent-fruited species of the Southwest may have horticultural importance in future. (See S. C. Mason, Journ. Agric. Research, 1913.)

In Europe and Eurasia, the fruit-bearing cherries and plums had their original development, chiefly from the three species-groups, *P. Cerasus*, *P. avium*, and *P. domestica*. Ornamental forms are incidental or secondary. In North America, the horticultural development has been chiefly in edible forms of plums. In the Orient—farther Asia and the Chino-Japanese region—the peach and apricot groups probably had their origin, as well also as the fruit known to us as the Japanese plum; but Japan is noted for its cherries cultivated for bloom rather than for fruits. Only the indifferent *P. Pseudo-Cerasus*, among the cherries, is natively grown for fruit in China and Japan.

The Japanese flowering cherries are singularly beautiful and attractive. They should be better known in this country. A number of forms have been long introduced and a few of them are advertised, but apparently they have not been carefully chosen as to hardiness and adaptability. David Fairchild reports that the trunks of the less vigorous forms of his ten-year-old collection in Maryland are sometimes winter-killed, especially on the southwest side, but there are many which, at least in Maryland, are hardy and form good-sized trees. The

3213. Flowers of plum. The ovary, or young plum, with the ovule inside, is at o. (Natural size.)

drooping single forms (*P. subhirtella* var. *pendula*) are among the hardiest and most showy from a distance, but are surpassed by the wonderful double forms (*P. serrulata*) which produce great masses of flowers as beautiful and quite as large as many semi-double roses. The question of stock is important. In Europe, nurserymen have generally grafted the Japanese cherry on *P. Cerasus* and *P. avium*, as well as on the Mahaleb. Most of the specimens of the pendula varieties commonly seen are grafted high on one of these stocks, but the effect in old specimens is grotesque and the trees are short-lived. The Japanese grafted trees sent to this country

are on a wild stock called the Mazakura (*P. Lannesiana*) which grows easily from cuttings and according to experiments made by the Department of Agriculture is almost immune to the cherry leaf-spot. As the grafting is at the surface of the ground, and as the trunks of the trees are the parts winter-killed, it is yet an open question as to whether the substitution of a longer-lived hardier stock would produce hardier longer-lived trees. E. H. Wilson, of the Arnold Arboretum, who has made a critical study of the Japanese cherries both in the Orient and at the Arboretum, thinks it will, and has suggested the trial for this purpose of *P. serrulata* var. *sachalinensis*. The Mazakura grows readily from cuttings, but *P. serrulata* var. *sachalinensis* does not. Buds have been successfully placed on the latter, and we shall be able to determine whether the stock transmits a greater longevity to them. With the tests being made by the Arnold Arboretum, the Department of Agriculture and in New York city, and the botanical studies of Wilson and Miyoshi, we should soon have a reliable planting of these very desirable oriental cherries. In anticipation of this, the names of many of the Japanese forms have been inserted in the following systematic account, although one may expect variations in the rendering of them into English.

In very recent years, the knowledge of the genus has been greatly extended by explorations in China, whence many new species (particularly in the subgenera *Cerasus* and *Padus*) have been derived that will probably find their way into cultivation. The taxonomy of the American native plums has also received much recent attention. Aside from the older writings of Bailey and Waugh on the native edible plums and cherries, see Hedrick, "The Plums of New York," 1911, and "The Cherries of New York," 1915 (also with similar accounts of all other pomological species), and Wight, "Varieties of Plums Derived from Native American Species," Bulletin No. 172, Bureau of Plant Industry, United States Department of Agriculture, 1915, and "Native American Species of *Prunus*," Bulletin No. 179 (1915). For the oriental *Prunus*, particularly those native in China, see the work by Koehne and others in "Plantæ Wilsonianæ," vol. 1, 1911-1913, and Wilson's "Cherries of Japan" (1916), published by the Arnold Arboretum, Boston. As this writing is being closed in the printery, a paper on the Japanese cherries appears in Japan: Miyoshi, "Japanische Bergkirchen," in Journ. Coll. Sci. Tokyo, vol. 34, art. 1 (1916) with eighty-nine colored figures.

KEY TO THE GROUPS.

- A. *Lvs. convolute in the bud* (i. e., rolled up, showing well as the lvs. begin to emerge from the bud): ovary usually furrowed lengthwise. There are exceptions in some of the American native plums (Nos. 14, 15, 19 and others) in which the lvs. are conduplicate in veneration; also No. 10: these species and their allies are intermediate between the true plums and the cherries.
- I. PRUNOPHORA, PLUMS, PRUNES, AND APRICOTS, Nos. 1-26.
- AA. *Lvs. folded or conduplicate* (trough-shaped, folded lengthwise along the midrib) in the bud.
- B. *Fr. normally soft-hairy* (except in 33 var.); stone or pit often furrowed and pitted: fl.-cup short and wide-spreading.
- II. AMYGDALUS, ALMONDS, AND PEACHES, Nos. 27-34.
- BB. *Fr. very juicy, glabrous or only very slightly hairy*; stone smooth or roughish.
- C. *Fls. in fascicles or cymes*.
- III. CERASUS, COMMON OR FASCICLED CHERRIES, Nos. 35-69.
- CC. *Fls. in racemes*.
- IV. PADUS, RACEMOSE CHERRIES, Nos. 70-82.

Subgenus I. PRUNOPHORA. Apricots and Plums.

Fr. sulcate, glabrous and usually glaucous (except in the apricots), the stone compressed and usually longer than broad and smooth or nearly so: fls. solitary or in umbel-like cymes, mostly appearing before the lvs. or with them: lvs. mostly convolute (but often conduplicate) in veneration, generally ovate or lance-ovate.

- A. *Apricots*—the fls. solitary or in 2's, before the lvs. and the fr. velvety (at least until ripe): stone usually sulcate on the margin: peduncle separating from the mature fr. See *Apricot*.

1. *Armeniaca*, Linn. (*Armeniaca vulgaris*, Lam.). COMMON APRICOT. Figs. 279-284, Vol. I. Small round-topped tree with reddish bark much like that of the peach tree: lvs. ovate to round-ovate, sometimes slightly cordate at the base, abruptly short-pointed, glabrous (at least above), closely serrate, the stalks

3214. *Prunus Mume* ($\times \frac{1}{2}$). No. 2.

stout and gland-bearing: fls. pinkish, solitary and sessile or very nearly so, appearing from lateral buds of last year's growth (sometimes on short year-old spurs) before the lvs.: fr. variable, nearly smooth when ripe, short-stalked like a peach, usually somewhat flattened, mostly yellow and overlaid more or less with red, the stone flat and smooth, ridged or sulcate on one edge. Probably Siberia (Dahuria, Manchuria) to China as a native plant. It early reached Eu., where it was once supposed to be native of Armenia, whence the name *Armeniaca*. The Russian apricot is a hardy race of this species. Var. *pendula*, Dipp., has hanging or pendulous

twigs. Var. *variegata*, Hort., has white-variegated foliage.—*P. Armeniaca* is apparently widespread in farther Asia and it is variable. By some authors the main forms are separated as species but the differences appear to be too unimportant or inconstant for clear definition and they are here retained as varieties.

Var. *sibirica*, Koch (*P. sibirica*, Linn. *Armeniaca sibirica*, Pers.). SIBERIAN APRICOT. Bush or small tree, 10 or 12 ft. high: lvs. small and glabrous, or sometimes sparingly bearded beneath, ovate to rounded, long-pointed, unequally crenate-serrate: fls. white or pink, appearing early in the season and usually in great profusion, subsessile, the calyx minutely puberulent: fr. globular, rarely more than $\frac{1}{2}$ in. diam., yellow with a reddish cheek, scarcely fleshy, practically inedible, finally splitting; stone smooth, very sharp-edged. Mongolia, Dahuria. L.B.C. 17:1627.—Sometimes planted as an ornamental bush.

Var. *mandshurica*, Maxim. (*P. mandshurica*, Koehne). Lvs. rounded, subcordate or cuneate at base, at apex long-cuspidate and acute, margin strongly double-toothed, the teeth sharp and twice longer than wide: peduncle long (about $\frac{1}{4}$ in.): fr. nearly globular, scarcely 1 in. long, yellow, red-spotted, succulent and sweet; stone small and smooth, the margin obtuse, the seed sweet. Manchuria.—Distinguished by the narrow sharp teeth and double serration of the lvs.; kept as a distinct species by some authors.

Var. *Ansù*, Maxim. (*P. Ansù*, Komar.). Lvs. broad-elliptic, at base short-cuneate, at apex acuminate, very glabrous, the margins crenate-serrate: peduncles hispid: fls. twin: fr. subglobose, deeply umbilicate or sulcate, red, tomentose, the flesh grayish brown and sweet and free from the minutely reticulated stone which has one very sharp edge. Japan; cult.—Retained as a separate species by some, being marked by the cuneate base of the lf.

2. *Mûme*, Sieb. & Zucc. (*Armeniaca Mûme*, Sieb.). JAPANESE APRICOT. Fig. 3214; also Fig. 279, Vol. I. Tree of the dimensions of the common apricot, but the bark greenish or gray and the foliage duller in color: branchlets green: lvs. relatively small, narrow-ovate to nearly round-ovate, long-pointed, finely and sharply serrate, more or less scabrous, lighter-colored beneath, the petioles mostly gland-bearing: fls. sessile or nearly so, fragrant: fr. mostly smaller than that of *P. Armeniaca*, yellow or greenish, the dry flesh adhering to the pitted stone. Japan, where it is much grown for its fls. Gn. 50:164. R.H. 1885:564. G.C. III. 29:183.—Planted to some extent in the S., particularly in the form known as Bungo or Bongoume apricot or plum, but of minor value. When top-worked on plum, it withstands the winters of Cent. N. Y., but does not bear. The apricot cult. as Chinese or Shense is also of this species. There are many double-fl. forms in Japan, where it is much prized for decoration. Var. *Goethartiana*, Koehne. Lvs. as in *P. Mûme*, rather large: calyx-tube and lobes pubescent. Japan. Var. *âibo-plêna*, Hort., fls. double, rose in bud then white. Gt. 52:1513b. Other Latin-named varieties are recorded, as forms *laciniata*, Maxim., var. *microcarpa*, var. *viridicalyx*, and var. *cryptopetala*, Makino.

3. *brigantiaca*, Vill. (*Armeniaca brigantiaca*, Pers. *P. Armeniaca* subsp. *brigantiaca*, Dipp.). ALPINE PLUM. Shrub or small thornless tree, with mostly smaller lvs. and smaller smooth subacid fr. the size of a small green-gage plum: lvs. broad-oval or ovate, the blade 2-3 in. long, abruptly short-pointed, very sharp-serrate, above glabrous or essentially so, beneath lighter-colored and more or less hairy on rib and nerves, the petiole gland-bearing and usually less than 1 in. long: fls. white, about $\frac{1}{2}$ in. across. French Alps.

4. *dasycarpa*, Ehrh. (*P. Armeniaca* var. *dasycarpa*, Koch). PURPLE or BLACK APRICOT. Small tree, of

the stature of the common apricot: lvs. smaller and narrower, mostly elliptic-ovate, finely and closely serrate, thin, dull green, the stalks slender and nearly or quite glandless; fls. large and long-stalked, showy; fr. globular and plum-like on a distinct st., pubescent at maturity, dark purple, the flesh soft and sourish; stone fuzzy. Probably native to Manchuria. B.R. 1243. L.B.C. 13:1250.—Sometimes planted, mostly as an ornamental tree, for the fr. has little value compared to that of the common apricot. Hardy in the N.

AA. *Plums*,—the fls. mostly in cymes, in most species appearing with the lvs. in the N. (before the lvs. in the S.), and the fr. smooth and glaucous: stone not prominently sulcate; peduncle slender, usually remaining with the fr. (exception in No. 12). See *Plum*, *Prune*.

B. Group of Eurasian plums: lvs. relatively broad, usually prominently reticulated and more or less pubescent (at least beneath), the young twigs mostly pubescent; fl.-clusters with mostly 1 or 2 fls. from each bud.

c. Fl.-sts. glabrous.

5. *cerasifera*, Ehrh. (*P. domestica* var. *Myrobalan*, Linn. *P. Myrobalana*, Loisel.). CHERRY PLUM. Slender twiggy grower, often thorny, the tree small or sometimes shrub-like; twigs usually soon becoming glabrous: lvs. rather small and thin, also lightish green, becoming nearly or quite glabrous, short-ovate and short-pointed, finely serrate; fls. rather small as compared with most forms of *P. domestica*, white or bluish, slender-stalked; fr. small (usually 1 in. or less diam.), globular and cherry-like, depressed about the st., yellow or red, the flesh soft, juicy, and sweet-flavored. Probably native to the Caucasus and S. W. Asia, although early attributed to N. Amer. B.M. 5934. Gn. 33, p. 252. J.H. III. 28:267.—The Myrobalan plum is a culture-form of this species, with rather large and good fr., by some regarded as a subspecies or variety *Myrobalana*. It is extensively used in this country as a stock on which to bud the domestica plums, the seedlings being imported in great quantities from Eu. It is a smaller tree than *P. domestica*, with much more slender growth, smoother twigs and lvs., smaller and mostly earlier fls., and also smaller softer fr. with a depression about the st. It tends to dwarf the domestica plums, but its influence in this direction is not sufficient to discourage its use as a stock. Its advantages as a stock are its cheapness, the ease with which all domestica varieties "take" on it, and the readiness with which it can be grown in the nursery row. It is not used to any extent as stocks for other plums than the domesticas. Spontaneous trees are sometimes found about old nursery grounds, and it occasionally appears in orchards when the top of a plum tree dies and sprouts arise from the root. There are also a few varieties prop. for the early juicy frs., but they are little known. It makes a good ornamental tree. The Marianna, much used for stocks of many kinds of plums in the S. (and growing from cuttings), is probably a hybrid of this species with *P. hortulana* or *P. angustifolia*. There are several cult. forms of *P. cerasifera*, one of the best being the plant known as *P. planeriensis*, Hort., with full double white and red fls. There are also forms with yellow- and white-variegated lvs., and a weeping form (var. *péndula*, Hort.). A form with narrow willow-like lvs. (var. *acutifolia* or *angustifolia*, Hort.) is also advertised. A form with twisted or contorted foliage is shown in R.H. 1895, p. 201.

Var. *Pissárdii*, Koehne (*P. Pissárdii*, Carr. *P. cerasifera* var. *atropurpurea*, Dipp.). A handsome form with purple lvs. and dark wine-red fr.—Intro. into

France by Pissard, gardener to the Shah of Persia, and first fully described in *Revue Horticole* in 1881. It is a cultural form of *P. cerasifera*. It is one of the best of all small purple-ld. trees, holding much of its color in the American summers. It seems to be hardy wherever the common plum will stand. The best color is secured on the strong growths; therefore it is well to head back the tree frequently. R.H. 1881:190; 1884:396. G.C. III. 1:416. Gn. 32:224; 55, p. 314. J.H. III. 28:287. G.M. 31:190, 191.—

A recent form known as *Spæthiana*, has very deep-colored and shining foliage, retaining its color (in Eu.) through summer and autumn. A form known as *Môseri flore-pleno* has

3215. *Prunus spinosa* (X 1/4). No. 7.

double pink fls. G.M. 55:819. The form called *Hessei* (*P. Pissárdii* var. *Hessei*, Purp.) has narrow irregularly cut and toothed usually long-acuminate lvs., red with a broad greenish yellow or crimson-red border. *Púrpusii* (*P. Pissárdii* var. *Púrpusii*, Hesse) has lvs. similar in shape to those of usual var. *Pissárdii*, dark red and variegated with yellow and bright rose. The form *nigra* has very dark purple lvs. *Blirieana* (*P. Blirieana flore-pleno*, Carr.) is a very handsome form with long slender branches bearing purple-tinted foliage and semi-double apple-blossom-pink fls. R.H. 1905:392. Gn. 78, p. 203. G.M. 57:334.

Var. *divaricàta*, Bailey (*P. divaricàta*, Ledeb. *P. cerasifera* subsp. *divaricàta*, Schneid.). Branching from the base, the branches wide-spreading and some of them nearly or quite prostrate: lvs. broader toward the base; fr. not depressed about the st., yellow. Macedonia to N. Persia. B.M. 6519.

6. *Cocomilia*, Ten. ITALIAN PLUM. Allied to *P. cerasifera*. Bush or small tree, with thorny branches and young growth glabrous: lvs. oval or broadly ovate to roundish obovate, sharp-serrate, glabrous above, more or less pubescent on nerves beneath or glabrous, tapering below, somewhat pointed: fls. usually in pairs, appearing with the lvs. or just preceding them, white or greenish white, the calyx-tube about the length of the pedicels: fr. small and yellow, globular or oblong-ovoid, rather good for eating. Italy.

7. *spinosa*, Linn. BLACKTHORN. Fig. 3215. Low and spreading, making a very thick thorny top, the young growths distinctly pubescent: lvs. small, oblong-ovate or elliptic-ovate, very numerous on the branches, nearly or quite obtuse, very finely and closely serrate: fls. white, small, borne singly or in pairs (or sometimes in 3's) and often on the thorns: fr. little larger than a very large pea, very deep glaucous-blue, usually persisting until winter, scarcely edible. Cent. and S. Eu. and N. Afr. to N. Persia and Siberia. G.C. III. 42:308.—Sometimes planted in this country, chiefly in the double-fl. form, var. *plena*, Hort. (Gn. 59, p. 76; 61, p. 363. G.M. 44:165). It is an excellent bush or small tree for protecting the borders and corners of drives and walks. The short stiff thorny branches make a good barrier. The tree is perfectly hardy where the plum can be grown. The little frs. are usually astringent, but there is a sweet-fruited form. It has been supposed by some that the domestica plums may have come from this species, but this is very doubtful, at least within the period of human experience with them. Var. *purpurea*, Hort., has purple foliage; fls. small and very numerous, pink; tree less spiny than the type.

cc. *Fl.*-sts. usually more or less hairy.

8. *doméstica*, Linn. (*P. communis*, Huds.). COMMON GARDEN PLUM. Figs. 3068 to 3072. Strong-growing small tree with pubescent twigs: lvs. large and thick, dull green, much reticulated, pubescent beneath, ovate or obovate, coarsely and irregularly serrate: fls. white, large, usually in clusters: fr. various, but firm in texture and usually not depressed about the st.; stone large, slightly rough or pitted.—Native country unknown, but of Eu. or the Eurasian region. If it exists in a truly wild state, it is to be sought in the Caucasus and trans-Caucasus regions. It is run wild in many parts of the world. Focke says that *P. doméstica* is unknown in an originally wild state, and that the typical form of the species is the prune (Zwetsche), *P. æconomica*, Borkh. There are various forms of *P. doméstica* grown for ornament, as double-fl., yellow-lvd., and variegated-lvd. As a fr.-plant it is widely variable. It is the parent species of the old-time or common plums, as distinguished from the Japanese and American plums. The synonymy of the main varietal groups is shown by Waugh, Bot. Gaz. 26, pp. 417–27 (Dec., 1898), and 27, pp. 478–81.

Var. *insititia*, Bailey (*P. insititia*, Linn. *P. doméstica* subsp. *insititia*, Schneid. *P. italica*, Borkh.). DAMSON, BULLACE, and probably also ST. JULIEN, and other kinds of plums. A form with small foliage and small firm oval or ovoid frs. borne mostly in clusters: tree small and compact.—Damson is a general name for small-fruited and small-lvd. forms of the plum. When the plum runs wild, it usually reverts to this form. Some of the Damsons (as the French, Shropshire, Farleigh) are commercial orchard varieties, being used for culinary purposes. The Mirabelle plum is *P. insititia* var. *syriaca*, Koehne. There is much difference of opinion as to the systematic position of the plum designated by Linnæus as *P. insititia*, but in character it is somewhat intermediate between *P. doméstica* and *P. spinosa*. It is probably one

stage in the reversion of the plum toward wild or half-wild forms. The *P. doméstica* var. *damascena*, Linn., is indefinite, and the name may well be dropped.

Other forms of *P. doméstica* have received Latin class-names, as var. *malifórmis*, Linn. (*P. syriaca*, Dipp.), including the Mirabelle (a small-lvd. form with small yellow fr., not unlike the Damsons) and others;

var. *Cerèola*, Linn., the green-gages or Reine Claudes; var. *galatensis*, Auth., the prunes. Var. *élégans*, Hort., a recent form, has narrow white-margined lvs.

BB. Group of oriental plums: lvs. relatively longer (mostly oblong-obovate), not roughened or pubescent, often shining, the young twigs glabrous or nearly so: fls. mostly 3's from each bud in the cluster.

9. *salicina*, Lindl. (*P. triflora*, Roxbg., nomen nudum. *P. japonica*, Hort., not Thunb. *P. Hattian*, Tamari. *P. ichangana*, Schneid. *P. Bòtan*, Hort. *P. Màsu*, Hort.). JAPANESE PLUM. Figs. 3216; also Figs. 3073, 3074. Strong-growing small tree, with smooth often shining reddish or cinnamon-brown twigs: lvs. mostly oblong-obovate, abruptly but prominently pointed, closely obtuse-serrate, the veins looping near the margin, bright often shining green above and dull beneath: fls. few from each bud (most commonly about 3), showy, white or very nearly so, slender-stalked: fr. various, mostly large and firm, yellow or light red (never blue-purple) with pronounced suture and tending to be pointed at the apex. R.H. 1895:160. Gn. 78, p. 195.—Chinese, but intro. into this country from Japan (in 1870), and now widely distributed and much grown for its fr. The Japanese plum is hardy, in some of its varieties, as far north as Ottawa. It is prized because of its great productiveness, long-keeping qualities and beauty of its fr., and its greater immunity from black-knot. As a class, the fr. is of lower quality than the domestica plums. The season of the Japanese plums begins considerably in advance of the domesticas and holds nearly as late. The greater number of the varieties are cling-stones, but there are some freestones among them. A race of hybrids with *P. hortulana* and *P. angustifolia* is now appearing.

Var. *pùbipes*, Bailey (*P. triflora* var. *pùbipes*, Koehne). Pedicels densely pubescent or only rarely subglabrous: calyx-tube pubescent a third or half the length.—Cult. abroad.

10. *gymnodònta*, Koehne. Shrub, with crowded unarmed branches: lvs. large and more or less fascicled, conduplicate in veneration, narrow-obovate or obovate-oblong, about 2–3 in. long, at base acute or cuneate; at apex short-acuminate and very acute, serrate with glandless teeth, glabrous or slightly hairy beneath; stipules linear or nearly filiform, often cut: fls. appearing with the lvs., white; calyx-lobes oblong and obtuse, entire or nearly so; petals spatulate-obovate, short-clawed, about ½ in. long: fr. not described. Manchuria. Cult. abroad.—From *P. salicina* (*P. triflora*) this species differs in the conduplicate lvs., which are little involute

3216. *Prunus salicina*.—Japanese plum.

From specimens in the herbarium at the Royal Gardens, Kew, as *P. triflora*, Roxbg. (No. 9.)

on margin, glandless lf.-serratures, very short pedicels and smaller fls.

11. *thibetica*, Franch. Ornamental tree, 15–20 ft., with blush-pink fls., and with convolute lvs. which are oblong and obtuse, crenate, the teeth glandular-callose at their apex: fls. with the lvs., on pedicels $\frac{1}{2}$ – $\frac{3}{4}$ in. long, bluish-pink; petals $\frac{1}{2}$ in. or less long, scarcely equalling the stamens. W. China, in thickets.

12. *Simonii*, Carr. (*Persica Simonii*, Decne.). SIMON or APRICOT PLUM. Fig. 3217. A straight-growing fastigate tree: lvs. rather long-oblongeolate or lance-ovate, somewhat thick and heavy, dull, very veiny below, finely but unevenly obtuse-serrate, conduplicate or trough-shaped in habit: fls. nearly white, on short stalks, often 2 or 3 together, preceding the lvs.: fr. 1–2 in. diam., flattened lengthwise, very firm in texture, perfectly smooth, handsome maroon-red, possessing a deep suture, the yellow flesh closely adhering to the small spongy-roughened nearly orbicular pit; peduncle usually not adhering to the mature fr. Named in honor of Eugene Simon, who sent pits from China to France, prior to 1872; botanical position in the genus doubtful, as it has some of the characters of apricots. The fls. are sometimes described as appearing with the lvs., but in N. Y., at least, they are distinctly precocious. China. Not known as a native plant. R.H. 1872:110. Gn. 70, p. 225.—Intro. into the U. S. about 1880, or shortly after. Although much advertised by nurserymen, it has not attracted great attention from fruit-growers in the E. On the Pacific slope it is popular. The fr. is usually bitter, with an almond-like astringency, but sometimes it is very palatable. The tree is very hardy and vigorous somewhat north of the limit of peach-growing, but, except in the Pacific region, it does not appear to be uniformly productive. The fr. is handsome, with a pleasing odor and it keeps a long time. The tree is conspicuous for its narrow erect growth. The fls. are borne on short spurs on wood 2 and more years old; also singly on the last year's growth. The Wickson plum is apparently a hybrid of this species and *P. salicina*.

BBB. Group of American or native plums: lvs. relatively narrow and smooth, and the young growth glabrous (*P. subcordata* and *P. americana* partial exceptions), the fr. comparatively small and in shades of yellow and red, not deep blue-purple: fls. mostly more than 3 (sometimes 2) from each bud in the cluster.

C. Lvs. mostly broad and thick, pubescent or roughish beneath, very sharply serrate or even jagged: fr. thick-skinned.

D. Shape of lvs. mostly oval to orbicular, and usually obtuse: far western.

13. *subcordata*, Benth. PACIFIC PLUM. Small tree or bush, usually only a few feet high, but sometimes rising to 20 or 25 ft.: lvs. round-ovate, or orbicular, obtuse, mostly broad or subcordate at base, either sharply or obtusely serrate (usually incised-serrate), thick, soft-pubescent beneath but becoming more or less glabrous: fls. white fading to rose, less than 1 in. across, in clusters of 4 or less and appearing before or with the lvs.: fr. globular or short-oblong, usually dark red, in the largest wild forms somewhat over 1 in. diam., the flesh subacid and clinging to the flat, smooth, or slightly roughened stone. High lands and mountains, Calif. and Ore. S.S. 4:154.—The fr. is gathered for domestic uses, and the tree is sometimes planted about settlements. It varies much, and the greater part of the trees do not produce agreeable fr. In many cases it is only a tree-like bush. The bark is blackish, and is sometimes pubescent on young shoots, which are reddish.

Var. *Kelloggii*, Lemmon. SISSON PLUM. Taller and more slender: bark ash-gray: lvs. usually not cordate,

orbicular or elliptical, nearly glabrous, but apparently not constantly different from the species itself: fr. larger (1 in. or more long), ovate, yellow or red, the flesh soft and palatable. N. Calif.—Much recommended by Mr. Sisson, near Mt. Shasta, whose name it bears, and now planted in some places in Calif. It is superior to *P. subcordata*. The tree rarely exceeds 15 ft. in height and 4–6 in. diam. of trunk. It seems to lack good botanical characters of separation from the type of the species.

Var. *oregana*, Wight (*P. oregana*, Greene). OREGON PLUM. Fr. pubescent at maturity: lvs. oval or ovate, not so large as usual in the type species, pubescent at least beneath. Ore.—Apparently not cult.

DD. Shape of lvs. on the ovate or oblong order, mostly acuminate: the *Americana* set, mostly with lvs. large in proportion to size of plant.

E. Stature of trees: lvs. and fls. large.

14. *americana*, Marsh. (*P. latifolia*, Moench. *P. hiemalis*, Michx., at least in part. *P. ignota*, Nels.). COMMON WILD PLUM. Figs. 3218, 3219; also Figs. 3075, 3076. Small twiggy spreading usually thorny tree

3218. *Prunus americana*, as it grows wild in New York ($\times \frac{1}{2}$). No. 14.

mostly forming thickets, with gray branches or gray-brown twigs: lvs. obovate, oblong-obovate or sometimes oblong-ovate, acuminate, thickish, the margins mostly sharp-serrate or sometimes almost incised, not glossy, strongly reticulated beneath and pubescent on the veins: fls. large, white, slender-stalked, the calyx-lobes entire and pubescent on the inside, appearing in small clusters in advance of the lvs.: fr. various, but mostly small and hard, the skin tough and glaucous and not shining, yellow and variously overlaid with red; stone turgid. Woods and copses. Mass. and N. Y. to Man., Utah, and New Mex., and in the E. to Savannah, Ga., and nearly to the Gulf; the most widely distributed of the native true plums. It sometimes reaches a height of 15–20 ft. S.S. 4:150.—In the E., the frs. are usually austere, and often not fit for eating; but in the W., edible-fruited forms are found in abundance. It is the most prolific source of cult. native plums for the cold N., giving rise to such varieties as Blackhawk, Cherokee, Craig, Forest Garden, De Soto, Golden Queen, Gaylord, Rollingstone, Newton, Hawkeye.

Var. *mollis*, Torr. & Gray (*P. lanata*, Mack. & Bush. *P. americana* var. *lanata*, Sudw.). Lvs. and shoots soft-pubescent or sometimes almost tomentose. Ill., Iowa, Mo.—To this form belong the Wolf, Van Buren, Quaker, and American Eagle plums. There is also a double-fl. variety.

15. *nigra*, Ait. (*P. borealis*, Poir. *P. mollis*, Torr. *P. americana* var. *nigra*, Waugh). CANADA PLUM. Lvs. mostly broader, the teeth glandular and remaining on mature lvs. as small callous points, but the teeth otherwise nearly or quite blunt and thereby differing from the sharply and deeply serrate lvs. of *P. americana*;

nevertheless a very distinct one. It never forms thickets, as does *P. americana* and its subspecies, but occurs always as a tree with a well-defined trunk, which in the older trees differs in its furrowed bark. The young leaves as they appear are mostly somewhat obtuse at the apex instead of acuminate; the older leaves are usually broader in proportion to their length, and the serration of the margin is slightly less pronounced. The flowers also have petals somewhat broader in proportion to their length than in *P. americana*, while the stone is obovoid or round and more turgid."

17. *hortulana*, Bailey (*P. hortulana* var. *Waylandii*, Bailey). HORTULANA PLUM. Fig. 3220. Tree distinct, not sprouting from the root or forming thickets or

3219. *Prunus americana*.—The Weaver ($\times \frac{1}{2}$). No. 14.

petioles bearing 2 glands, near the top: fls. larger, on slender dark red pedicels, white changing to pink, the calyx-lobes glandular-serrate and glabrous on the inside: fr. mostly somewhat oblong and orange-red, the stone large and much compressed. New Bruns. to Assiniboia, and in New England, N. Y., Mich., Wis., and N. Ohio; possibly intro. in some of its southern ranges. S.S. 4:149.—A more showy tree than *P. americana*, blooming earlier, and in its extreme forms appearing to be very distinct. It has given rise to some of the best fr.-bearing varieties, such as the Cheney, Itasca, Oxford, Aitkin, Crimson, although not nearly so prolific of cult. forms as *P. americana*.

16. *mexicana*, Wats. (*P. australis*, Muns. *P. reticulata*, *P. tenuifolia*, *P. polyandra* and *P. arkansana*, Sarg.). BIG-TREE PLUM. The southern representative of *P. americana*, as *P. nigra* is the northern: it is tree-like, not sprouting from the roots or forming thickets: lvs. oblong-obovate to obovate, 3–5 in. long, rounded or subcordate at base, abruptly acuminate at apex, sharply and sometimes doubly serrate, short-pubescent above at least when young and long-pubescent beneath (and often confused with *P. americana* var. *mollis*); petiole usually bearing 1 or more short-stalked glands at or near the apex: fls. $\frac{3}{4}$ in. across, white, in small nearly sessile umbels, the pedicels usually glabrous; calyx-lobes mostly reflexed, nearly or quite as long as the tube, dentate at apex or sometimes entire, obscurely glandular, pubescent within; petals variable in shape, usually pubescent and mostly entire: fr. globose or rarely oblong, sometimes 1 in. or more diam., purplish red with bluish bloom; pit or stone obovoid or nearly globular, turgid, the surface smooth or essentially so. S. W. Ky. and W. Tenn. to Okla. and Mex.—Wild fr. is sometimes gathered, and it varies in size and quality, but the species has received little attention horticulturally, although used experimentally as a stock to which its non-suckering habit adapts it. It is said that a hybrid has been produced with *P. salicina*. Wight, who has recently re-characterized this species, writes that "Although long confused with *Prunus americana*, and in the herbarium sometimes difficult to distinguish from *P. americana* var. *lanata*, the species is

fr. globose or short-oblong, $\frac{3}{4}$ –1 in. diam. in the wild, red to yellow and mostly white-dotted, with little or no bloom, not thick-skinned; pit or stone various, globose to oval or oblong, the surface more or less reticulated. Cent. Ky., Tenn., to Iowa and Okla.—This species has yielded a good number of cult. varieties, as Kanawha, Golden Beauty, Cumberland, Leptune, Wayland, Moreman, Sucker State. The species was first distinguished in 1892 to designate varieties of plums intermediate between *P. americana* and *P. angustifolia* (the two species at that time clearly separated); these intermediate varieties were then said to "represent at least two other species, and perhaps even more" (G.F. 5:90), one of which it was proposed to separate as *P. hortulana*. Later students have separated *P. Munsoniana* from these varieties, and have redefined other species. Subsequently it was supposed that *P. hortulana* represents a range of hybrids between *P. americana* and *P. angustifolia*, and it is not yet known what part hybridization has played in the origin of these forms, although the evidence accumulates that separate specific types are involved.

Var. *Mineri*, Bailey, is nearer to *P. americana*, and represents the northward extension of the group; it is known by its thicker and duller lvs. which are very veiny below and coarsely toothed and somewhat obovate in outline, and by a late firm fr.

3220. *Prunus hortulana* ($\times \frac{1}{2}$) No. 17.

To this form belong the Miner, Langsdon, Clinton, Forest Rose. The Miner is apparently the first horticultural variety of native plum to receive a name; the seed that produced the original tree was planted in 1814.

EE. *Stature of bushes: lvs. and fls. small: far S. W.*

18. *rivularis*, Scheele (*P. texana*, Scheele). CREEK PLUM. Slender-stemmed shrub to 8 ft., forming thickets, with gray or reddish twigs and early-ripening fr. (June):

3221. *Prunus angustifolia* var. *Watsonii* ($\times \frac{3}{8}$). No. 20.

lvs. ovate to oblong-ovate or somewhat obovate, rounded at base, short-acuminate at apex, 1–3 in. long, glandular-serrate, glabrous above, more or less pubescent beneath; petioles with 1 or 2 glands near apex, or glandless: fls. white, with the lvs. or before them, less than $\frac{1}{2}$ in. broad, on slender glabrous pedicels; calyx-lobes as long as tube, ovate or oblong-ovate, usually pointed, glandular, little pubescent on exterior, with age reflexed; petals obovate-orbicular or oblong-ovate, short-clawed: fr. nearly globose, $\frac{1}{2}$ in. or somewhat more diam., red and with light bloom; pit or stone oval to subglobose, the surface smooth or obscurely roughened. Texas.—Apparently of little horticultural value, as the fr. is small and poor, although eaten by Indians. No improved varieties are reported.

19. *Réverchonii*, Sarg. (*P. pygma*, Muns., not *P. pygma*, Willd.). HOG PLUM. Shrub, 2–6 ft., with gray bark and chestnut-colored twigs, forming dense thickets and yielding late-ripening fr. (Aug., Sept.): lvs. ovate-lanceolate (sometimes lanceolate), acuminate, usually 3 in. or less long, strongly conduplicate, either rounded or narrowed at base, glandular-serrate, glabrous and green above, pale and somewhat pubescent beneath; petiole bearing 2–4 glands near apex: fls. with the lvs. or preceding them, white, less than $\frac{1}{2}$ in. broad, on glabrous pedicels; calyx-lobes oblong or ovate-oblong, obtuse, glandular; petals obovate to oblong-ovate, narrowed or somewhat clawed, entire, or erose near apex: fr. globose or nearly so, sometimes nearly 1 in. diam., usually yellow (rarely red) and blushed with orange or crimson and marked with whitish dots, with little or no bloom; stone oblong, the surface smooth or slightly reticulate. Okla., Texas.—No horticultural varieties of this species are recorded; its fr. is sometimes good, although usually poor. Said to be well adapted to limestone soils and to withstand drought. Wight writes that the species is closely related to *P. rivularis* and may be a form of it. "The apparent differences are its more branching and less slender stems, trough-shaped leaves, later-ripening fruit, and more pointed stone."

cc. Lvs. mostly narrow and peach-like, firm, and more or less shining, glabrous, the young growths not pubescent: fr. thin-skinned: the Chickasaw and Wild Goose set.

20. *angustifolia*, Marsh. (*P. Chicasa*, Michx. *P. stenophyllus*, Raf.). CHICKASAW PLUM. MOUNTAIN CHERRY. Small bushy-topped twiggy tree, 8–10 ft. high or often only a shrub forming dense thickets, with slender zigzag reddish branches: lvs. lanceolate or oblong-lanceolate and conduplicate (trough-like), shining, 2 in. or less long, mostly narrowed toward base, at apex acuminate or short-acute, glabrous or sometimes sparingly pubescent on nerves beneath, finely and closely serrate; petiole glandular or not near apex: fls. white, preceding lvs., about $\frac{1}{2}$ in. across, on glabrous pedicels; calyx-lobes ovate-obtuse and shorter than tube, not glandular, exterior glabrous: fr. small and early, cherry-like, slender-stemmed, red or yellow and yellow-dotted, shining, thinly glaucous, the flesh soft and juicy and clinging to the small rough stone. Del. to Fla. and Texas, being abundant in sandy places. S.S. 4:152.—This species has given rise to several pomological varieties, as Caddo Chief and Ogeeche; it is an early-fruited species, more or less thorny.

Var. *Watsonii*, Waugh (*P. Watsonii*, Sarg.). SAND PLUM. Fig. 3221. Bush, 3–6 ft. high, with more zigzag twigs than in *P. angustifolia*, more spiny, the lvs. smaller, less pointed and less conspicuously serrate, the fls. smaller, the fr. with thicker skin. Dry regions of Kans. to Texas and New Mex. (also reported from Neb. but perhaps intro.), and planted by the settlers, who prize it for its fr. G.F. 7:135 (adapted in Fig. 3221). Several named pomological varieties issue from this variety, as Strawberry, Welcome, Red, Yellow, and Purple Panhandle. Var. *Watsonii* is named for Dr. Louis Watson, of Kans.

Var. *varians*, Wight & Hedr. BIG CHICKASAW PLUM. Rather larger than *P. angustifolia* itself, more robust and a less crabbed grower, lvs. and pedicels longer, and stone usually more pointed at apex. Okla., Texas, in more fertile soil than the species.—Apparently a range of forms growing under better conditions than those in which the plants taken as the type of *P. angustifolia* are found, and giving rise to many early-fruited plums, such as Yellow Transparent, Emerson,

3222. Leaf of *Prunus Munsoniana*.—The Newman plum ($\times 1$). No. 21.

Coletta, Clark, African. Supposed to have furnished hybrids with *P. Munsoniana* and *P. salicina*. The Marianna most probably represents a cross between some form of *P. angustifolia* (perhaps var. *varians*) and *P. cerasifera*.

21. *Munsoniana*, Wight & Hedr. WILD GOOSE PLUM. Figs. 3222, 3223; also Figs. 3076, 3077. A range of forms separated out of the old Hortulana class, of larger and freer growth than the variants of *P. angustifolia*, harder, with larger and more pointed lvs., and larger fls. bearing glandular calyx-lobes: forming thickets, reaching 20–25 ft. in height: lvs. 3–4 in. long, lanceolate to oblong-lanceolate, rounded at base, at apex acute or acuminate, margins closely glandular-serrate, shining and glabrous, usually slightly pubescent on veins beneath; petioles usually with 2 glands near apex. fls. white, $\frac{1}{2}$ in. or more broad, either with the lvs. or preceding them, on slender glabrous pedicels; calyx-

lobes ovate-oblong to oblong, obtuse, equaling the tube, glandular on margin, mostly glabrous on exterior: fr. globular or oval, bright red or yellowish and marked with whitish dots, late-ripening; pit or stone mostly oval, pointed at apex, the surface usually roughened. Ky. and Tenn. to Miss., Texas, Mo., and Kans.—The botanical status of this group is yet doubtful, although well marked in some forms. From it have come many pomological forms, as Wild Goose, Newman, Milton, Robinson, Pottawattamie, Osage, Whitaker, Jewell, and Texas Belle.

ccc. *Lvs.* mostly as narrow as lanceolate-ovate, or else small and shortish, thin or thinnish (except *P. maritima*), finely and usually evenly serrate, becoming glabrous or nearly so (except in forms of *P. umbellata* and *P. maritima*), beneath at maturity: fr. mostly thick-skinned. Species of the beach plum or *P. maritima* group, mostly plants of low growth and dwarf habit.

22. *orthosépala*, Koehne. Fig. 3224. A much-branched spreading bush about 4 or 5 ft. high, with young branchlets chestnut-colored: *lvs.* oblong-lanceolate to obovate-lanceolate, about 2 in. or less long, narrowed at base, at apex acute or acuminate, glabrous and shining, serrate; petiole glandless or with 1 or 2 glands near apex: fls. white, or pink with age, about $\frac{1}{2}$ in. broad, on glabrous pedicels; calyx-lobes oblong-obtuse, ciliate on margins, glabrous or nearly so on the exterior: fr. late, globose, about 1 in. diam., red, white-dotted, with bloom; stone oval, rounded at apex and slightly pointed at base, the surface somewhat rugose.—Not clearly known in the wild, but probably from Kans. to Texas. The Laire, grown in Kans. for the fr., is perhaps to be referred here. The species was founded on plants grown in the Arnold Arboretum from seeds said to have been sent from S. Texas. G.F. 7:187 (reduced in Fig. 3224).

23. *alleghaniensis*, Porter. ALLEGHANY PLUM. Fig. 3225. Tree, 12–15 ft., or oftener a straggling bush, usually not thorny, the young growth reddish and glabrous: *lvs.* lance-ovate to elliptic-obovate, about 3 in. and less long, prominently acuminate, sharply fine-serrate, pubescent on the veins beneath but becoming glabrous with age; petiole usually glandless but sometimes with glands at apex: fls. small ($\frac{1}{2}$ in. across), white, in clusters of 2–5, appearing with or before the *lvs.*, the calyx minutely pubescent and with narrowly oblong-ovate slightly hairy lobes, the petals round-obovate: fr. globular or ovoid, $\frac{5}{8}$ in. or less diam., dark purple with a heavy bloom, acid in flavor and often austere;

stone somewhat obovoid and obtusish at apex, the surface slightly roughened. Pa., Conn. S.S. 4:153. G.F. 3:429, from which Fig. 3225 is reduced.—In a very limited way the species has come into botanic gardens and collections. As an ornamental subject it has merit, for it bears profusely of fls. and fr. The plums, or

3224. *Prunus orthosépala* ($\times \frac{1}{2}$). No. 22.

“sloes,” are collected from the wild for the making of pies and preserves.

Var. *Davisii*, Wight, along gravelly ridges in the northern part of the southern peninsula of Mich., bearing blue frs. used locally for jellies and preserves, is distinguished by *lvs.* broader in proportion to their length and less acuminate. From *P. maritima*, which it resembles, it differs in the reddish color of twigs, more glabrous *lvs.* and pedicels, and the stone pointed rather than rounded at base.

24. *umbellata*, Ell. BLACK SLOE of the S. Twiggy small tree (10–20 ft.), with compact head and very slender glabrous branchlets, often more or less thorny: *lvs.* small (mostly 2 in. or less long), light green and rather thin, oblong, lanceolate, oblong-lanceolate or oval, obtuse or acute, closely serrulate, sometimes very closely pubescent beneath even at maturity; petiole without glands: fls. small to medium in size ($\frac{1}{2}$ – $\frac{3}{4}$ in. broad), white, on slender glabrous pedicels in few-fl. umbels, appearing with or just before the *lvs.*: fr. small, globular, slender-stalked, from pure yellow to orange-yellow and red-blotched, thinly glaucous, the flesh usually sour and bitter and free from the oval or subglobose stone. Near the coast from S. C. to Fla. S.S. 4:155.—Not intro. as a fr.-plant, but sometimes planted for the profusion of its white fls. The fr. is not unlike a cherry in shape, and is sometimes used in preserves. The foliage suggests *P. cerasifera*.

Var. *injucúnda*, Sarg. (*P. injucúnda*, Small. *P. mitis*, Beadle). A hill-country form: *lvs.* oval or oblong-oval, usually somewhat longer and broader than in *P. umbellata* itself, narrowed toward the base, acute or acuminate, mostly pubescent beneath and somewhat pubescent above: fls. appearing later (March, April); calyx pubescent rather than glabrous. N. C. to Ga., Ala., and Miss., apparently passing into var. *tarda*.

3223. *Prunus Munsoniana*.—The Wild Goose plum ($\times \frac{1}{4}$; stones $\times \frac{1}{2}$). No. 21.

Var. *tárda*, Wight (*P. tárda*, Sarg.). Tree, 18–20 ft., distinguished from *P. umbellata* by lighter-colored bark, later-ripening fr., and more oblong stone. W. Miss. to Texas and S. Ark., the nearly globular, yellow, red, purple, or blue fr. (about $\frac{1}{2}$ in. diam.) ripening in Oct. and Nov.

25. *maritima*, Marsh. (*P. pygmæa* and *P. sphærica*, Willd. *P. sphærocérpa*, and *P. acuminata*, Michx.

3225. *Prunus alleghaniensis* ($\times \frac{1}{4}$). No. 23.

P. pubescens, Pursh. *P. littoralis*, Bigel. *P. pubigera*, Steud.). BEACH PLUM. SHORE PLUM. Fig. 3226. Decumbent straggling more or less thorny bush with rough and warty branches and slightly pubescent young growth; lvs. oval or obovate-oval, short-acute or nearly obtuse, closely serrate, dull green, often somewhat pubescent beneath; fls. small, white, slender-stalked, borne in few-fl. umbels preceding the lvs.: fr. about $\frac{1}{2}$ in. diam., depressed-globular (somewhat flattened at the ends), with a slight cavity about the st., mostly deep dull purple when ripe and covered with a heavy bloom, the flesh brittle and mostly sweet and juicy and free from the small turgid cherry-like stone (which is pointed at both ends), the skin thick, tough, and more or less acrid. Sands of the seashore, New Brunswick, to Va., and also some miles inland; its reported occurrence at the head of Lake Michigan has not been verified. B.M. 8289. Gng. 4:257 (bush in bloom).—The main sts. are decumbent, and strong shoots stand upright to a height of 2–6 ft., or sometimes even 10–12 ft. *P. maritima* is a handsome plant in cult. because of the great profusion of its early spring bloom, and the frs., when produced, are also ornamental. As a fr.-plant, it is known in the variety Bassett American, which, however, has never become popular because of its small size. The species is very variable, and no doubt several botanical varieties could be distinguished. Yellow-fruited forms are known (forma *fláva*, G. S. Torr.). A species related to *P. maritima*, but not in the trade, is *P. Grævesii*, Small, with orbicular very obtuse and often apiculate lvs. and stone pointed only at base. Known only from the original locality at Groton, Conn., near Long Island Sound, an unarmed bush about 3 ft. high, with a dark rather rough bark and usually puberulent twigs.

26. *gracilis*, Engelm. & Gray. OKLAHOMA PLUM. A straggling shrub, closely allied to *P. maritima*, in clumps or thickets, 1–4 ft. high, with grayish bark and reddish brown pubescent young twigs: lvs. oval or ovate, rarely ovate-lanceolate, 1–2 in. long, narrowed either way but sometimes obtusish at apex, finely but lightly pubescent above, strongly pubescent beneath, finely serrate; petiole glandless or with 1 or 2 glands near apex; fls. preceding the lvs., white, $\frac{1}{2}$ to nearly $\frac{1}{2}$ in. broad, on pubescent pedicels; calyx-lobes ovate and acute, entire or denticulate, glandless; fr. globular or ovoid, $\frac{1}{2}$ – $\frac{3}{4}$ in. diam., mostly red and with light

bloom; pit or stone oval, somewhat obtuse at the ends, the surface nearly smooth. W. Ark., Okla. and N. Texas, in dry sandy places.—This species appears to have yielded no named pomological varieties, although the fr. is sometimes collected from the wild for market. *P. venulosa*, Sarg., is a larger shrub, forming denser thickets, with larger and more coarsely serrate lvs. and glabrous pedicels. It is from N. Texas, but whether a good native species or a hybrid of *P. gracilis* and *P. Reverchonii* is undetermined; of no horticultural promise.

Subgenus II. AMYGDALUS. Almonds and Peaches.

Fr. sessile, large, mostly pubescent: fls. solitary from lateral buds on the previous year's growth, appearing in advance of the lvs., the latter conduplicate in the bud.

A. Plant low and bushy as seen in cult.: flowering almonds.

27. *triloba*, Lindl. (*Amygdalus pedunculata*, Bunge. *Amygdalopsis Lindleyi*, Carr. *Prunopsis Lindleyi*, André. *Prunus ulmifolia*, Franch.). FLOWERING ALMOND. (See Nos. 39, 40.) Fig. 3227. Lvs. broadly ovate or obovate, usually broadest above the middle, soft-hairy, abruptly pointed, coarsely doubly serrate, tending to be 3-lobed above; fls. solitary, short-pedicelled, and mostly in advance of the lvs., clear pink, sometimes white, usually double (var. *plena*, Hort. Fig. 3234); calyx-tube hairy inside between stamens, the sepals pilose or glabrous on outside; sepals and petals (in single fls.) 5–10: fr. small, red-hairy when young, but becoming glabrous. China. B.M. 8061. I.H. 8:308. F.S.15:1532. R.H. 1862:91; 1870, p. 388 (fr.); 1883, p. 367 (fr.); 1884:396; 1907, pp. 154, 155. Gn. 21, p. 275; 28:346; 55, p. 374; 59, p. 135; 79, p. 17. G.M. 44:210; 52:247. G. 26:462; 33:19. H.F. II. 7:139. Gng. 5:165; 6:289; 8:196.—A most desirable bush, hardy in Cent. N. Y. and Ont. It is a good subject for blooming in pots. It is sometimes grown as a standard worked on plum, but it is then short-lived; better results are to be expected from own-rooted plants (by layering or root-grafting). Sometimes it rises to the stature of a small tree. The double-fl. form (var. *plena*) is the one commonly seen in grounds, but the single-fl. form is the better. A sport producing several pistils has been recorded (*Amygdalopsis*). Not to be confounded with the forms of *P. japonica* and *P. glandulosa*, which have smaller and relatively longer-stalked fls. and usually more than 1 from the bud, and different lvs.

Var. *Pétzoldii*, Bailey (*P. Pétzoldii*, Koch. *P. virgata*, Hort.). Branchlets and adult foliage glabrous: lvs. ovate or elliptic, usually at or below the middle, not 3-lobed, gradually narrowed or acuminate above, glabrous, with narrow sharp teeth; fls. smaller than in *P. triloba* and with shorter pedicel, rose-colored; calyx-tube glabrous inside as are the lobes or sepals on the

3226. *Prunus maritima* ($\times \frac{1}{4}$). No. 25.

outside, the sepals and petals usually 10; fr. spherical; stone hard, bony and more rugose. Probably China.

28. *orientalis*, Koehne (*Amýgdalus orientális*, Mill. *A. argentea*, Lam.). ORIENTAL ALMOND. Shrub, 3-10 ft. high, with woolly twigs; lvs. small ($\frac{3}{4}$ - $1\frac{1}{2}$ in. long), nearly or quite sessile (petiole less than $\frac{1}{2}$ in. long), oval, oblong or narrow-obovate, nearly obtuse or short-

3227. Dwarf almonds. *Prunus nana* at left; *P. glandulosa* in middle; *P. triloba* at right in the lobed form that sometimes occurs on spring or strong shoots. ($\times$ about $\frac{1}{2}$)

pointed, entire or obscurely serrulate; fls. solitary, nearly 1 in. across, light rose-color, with or just preceding the lvs.: fr. ovate or oblong, more or less pointed, thinly pubescent but becoming glabrous. Asia Minor, Syria. L.B.C. 12:1137.—Variable; several species-names of the same general geographical region are probably to be referred to it, or they may represent very closely related species.

29. *nana*, Stokes (*Amýgdalus nana*, Linn.). RUSSIAN ALMOND. Fig. 3227. Bush, 3-5 ft. high; lvs. narrowly elliptic or elliptic-lanceolate, 2 or 3 in. long, thick and rather stiff, scarcely pointed, lighter colored and the veins prominent beneath, smooth, the edges set with sharp spreading saw-like teeth; fls. usually solitary, rose-color or white, nearly 1 in. or less across, sessile, with or just preceding the lvs.: fr. small and hard, pubescent, bitter, with a large wrinkled sharp-pointed somewhat cordate, unequal-sided pit. Russia and W. Asia. B.M. 161. L.B.C. 12:1114.—This plant has been intro. into this country recently as a fr.-plant, although it possesses little merit for that purpose. It is cult. in Eu. for its fls. and it has been thought that the flowering almond of our gardens belongs to it; but our flowering almonds are *P. triloba* and also in part *P. glandulosa* and *P. japonica*. This Russian almond is very hardy, enduring the climate of the northern Prairie states, where it ripens its little almond-like frs. in July. A small-fruited form of the apricot (*P. Armeniaca*) has been intro. as Russian almond. *Prunus nana* is cult. in 2 or 3 forms. Var. *campéstris*, Hort., has white fls. of larger size. Var. *geórgica*, DC., has dark rose-colored somewhat smaller fls. and narrower, longer lvs. Var. *cochin-chinénsis*, Hort., is a larger plant with white fls. Var. *rúbra*, Hort., has red fls. over $\frac{1}{2}$ in. across. G.C. III. 52: suppl. Nov. 23 (1912). For another use of the name *P. nana* (for the choke cherry), see No. 72.

30. *Sweginzówii*, Koehne. Small glabrous shrub very like *P. nana*, distinguished by large and lf.-like stipules and unequal very sharp double teeth of the lvs.: fls. deep rose-colored; calyx tubular, nearly $\frac{1}{2}$ in. long, the lobes oblong and glandular-fimbriate; petals oblong-obovate with cuneate base, nearly $\frac{1}{2}$ in. long. Turkestan.

31. *Fenzliana*, Fritsch. Much like *P. communis*, but lower and more bushy and thorny; lvs. smaller, gray-green or bluish green; fls. more nearly white; fr. more peachlike in form, being not so pointed or elongated as in *P. communis*, but scarcely fleshy; stone shorter and more nearly orbicular in outline. Caucasus.—Said to be a very showy early-blooming species.

AA. Plant a tree or tree-like.

B. Fr. hard, splitting at maturity.

32. *communis*, Fritsch (*Amýgdalus communis*, Linn. *Prunus Amýgdalus*, Stokes). ALMOND. Figs. 161-163, Vol. I. Peach-like tree, 10-25 ft. tall, with gray bark; lvs. lanceolate, firm and shining, very closely serrate; fls. large (1 in. and more across), solitary and appearing before the lvs., pink, showy; fr. a large compressed drupe with hard flesh, splitting open at maturity and liberating the pitted stone (or almond). Asia. Gn. 50:312 and G. 29:291 (var. *macrocarpa*); Gn. 54:122.—Grown as an ornamental tree, but chiefly for the nuts (pits or stones of the fr.). There are double-fl., white-fl., and variegated-lvd. forms, also dwarf and weeping forms, under such names as *albo-plena*, *roseo-plena*, *purpurea*, *compacta*, *variegata*, *pendula*. The forms may be ranged in two classes: Var. *týpica*, Schneid., the hard-shelled almond, grown mostly for ornament, although there are bitter-kerneled and sweet-kerneled forms (vars. *amara* and *dulcis*); var. *frágilis*, Schneid., the soft-shelled or brittle-shelled almond, of which there are also vars. *amara* and *sativa*. See Almond. *P. persicoides*, Asch. & Graebn. (*Amýgdalus communis* var. *persicoides*, Ser. *A. persicoides*, Zabel), is an old hybrid of *P. Persica* and *P. communis*, with foliage much like the latter but usually more sharply toothed, and fr. intermediate or perhaps more peach-like, usually ovoid-obtuse and little succulent.

BB. Fr. soft and fleshy, usually not cracking or opening to the stone.

33. *Pérsica*, Sieb. & Zucc. (*Amýgdalus Pérsica*, Linn. *Pérsica vulgaris*, Mill.). PEACH. Figs. 2785-2791. Much like the almond in botanical characters and by some thought to be derived from that plant, but now generally agreed to be an original species and to be native to China (Fig. 2791, p. 2495): lvs. broad-lanceolate or oblong-lanceolate, coarsely serrate, the petiole usually gland-bearing and $\frac{1}{2}$ in. or less long (shorter than the width of one side of lf.-blade); fls. solitary, pink, appearing before the lvs., the sepals more or less pubescent on outside; fr. soft, pubescent at maturity, the stone deep-pitted and very hard. Widely cult., especially in N. Amer., where it thrives under a great variety of conditions.—There are 2 well-marked forms, the cling-stones or paves (*Persica vulgaris*, Risso), and the freestones (*Persica domestica*, Risso). There are many ornamental forms of the peach tree: double-fl., Fig. 2789. (F.S. 10:969; 13:1299, 1300; R.H. 1852:221); white-fl., dark-fl., etc.; purple-lvd.; variegated-lvd.; dwarfs. These forms are catalogued

3228. *Prunus Davidiana* ($\times \frac{1}{4}$). No. 34.

XCIII. *Prunus serrulata* var. *sachalinensis*.—The form *Eugenzo*.

under such names as *Persica vulgaris flore albo-plena*, *flore roseo-plena*, *flore sanguinea plena* representing different colors of double-fl. peach, and *P. vulgaris foliis purpureis* representing the purple- or blood-lvd. peach. One of the best of these fancy forms is var. *camelliaeflora*, Hort., with its subvar. *plena*, the former with very large carmine fls. and the latter with double fls. (Fig. 2789). There are forms (var. *versicolor*) with different colors of fls. on different branches of the same tree; also compact or dwarf, pyramidal, weeping, and purple-lvd. forms. See *Peach*.

Var. *nucipérsica*, Schneid. (*Amýgdalus Pérsica* var. *nucipérsica*, Linn. *Pérsica nucipérsica*, Borkh. *Pérsica lævis*, DC. *Prúnus Pérsica* var. *lævis*, Gray. *Amýgda-*

3229. *Prunus pumila*.—Sand cherry ($\times \frac{1}{2}$). No. 35.

lus nectarina, Ait. *Prúnus Pérsica* var. *nectarina*, Maxim.). NECTARINE. Fig. 2453, p. 2116. Fr. smooth, usually smaller: lvs. usually more strongly serrate. The nectarine is said to have sprung from the peach, both through seed- and bud-variation. There are 2 types, as in the peach: clingstones or *brugnons* (*Persica lævis*, Risso), and freestones (*Persica violacea*, Risso). The nectarine is not generally cult. in this country, although it is popular in Calif.

Var. *platycárpa*, Bailey (*Pérsica platycárpa*, Decne.). FLAT PEACH. Fr. much flattened endwise, and scarcely thicker in that direction than the length of the pit or stone, with a calyx-like eye or broken cavity at the top; stone small, flat, compressed, rough, and irregular. China. R.H. 1870:111. Trans. Hort. Soc., Lond. 4:512.—Grown in the southern states, where it has given rise to various globular peaches. The Peen-to is a form or variety (Fig. 2784, p. 2493) originated in 1869 with P. J. Berckmans, Augusta, Ga., from seeds sent from Austral., where it was probably intro. from China; on account of its very early blooming, this variety is not grown commercially in any of the regular peach sections of the U. S., as it is very likely to be caught by frosts, nor is the quality superior; for S. Fla. and the tropics, it is of value; the fr. is of medium size, strongly flattened on the ends, greenish, with red cheek, flesh light yellow and of good flavor but with a slight bitter-almond taste, cling, the stone small and flat.

34. *Davidiána*, Franch. (*Pérsica Davidiána*, Carr. *Prúnus Pérsica* var. *Davidiána*, Maxim.). Fig. 3228. Slender willow-like tree: lvs. narrower and smaller than those of the peach, tapering from near the base into very long acuminate points, very sharp-serrate, light green, willow-like: fls. appearing very early, 1 in. or more across, bluish or light pink, solitary, the sepals glabrous: fr. nearly globular, the suture prominent, about 1 in. diam., pubescent, grayish or yellowish; stone small and nearly spherical, ruminate, free from the whitish dry flesh. China. R.H. 1872, p. 75. G.F. 10:503. Gt. 44:1412. G.C. III. 11:529. Var. *álba*, Bean (var. *albiflora*, Schneid. *Pérsica Davidiána* var. *álba*, Carr.). Fls. white. Gn. 50, p. 165. G. 28:5. Somewhat grown as an ornamental subject. Hardy in the North, but the fl.-buds are usually killed. It blooms very early, much in advance of peaches. It is

said to be used in China as stock for many stone-fruits, and tests (particularly as a peach stock) are now under way in this country.

Subgenus III. CERASUS. Cherries.

Fr. globular or oblong, not sulcate, glabrous and usually not glaucous, the stone turgid (usually nearly globular), and rarely conspicuously longer than broad and smooth: fls. in umbel-like fascicles (mostly solitary in *P. tomentosa*), commonly with or immediately preceding the lvs.

A. Fls. arising from 2 lateral buds (the central one usually a lf.-bud or branch-bud) on the previous season's growth, usually appearing in advance of the lvs.; the pedicels having no common peduncle outside or beyond the bud-scales: petiole usually very short: plant dwarf. (*Microcerasus*.)

B. Sepals or calyx-lobes reflexed: fls. pedicelled and umbellate, 4 or less (sometimes only 1).

C. Lvs. entire at base or below the middle, very shallowly serrate toward the apex: fr. black at maturity.

35. *pumila*, Linn. SAND CHERRY. DWARF CHERRY. Fig. 3229. Decumbent or prostrate at the base when old, but the young growth strictly erect and often reaching 5–8 ft. in height, the slender twiggy growth reddish and glabrous: lvs. narrowly oblanceolate, acuminate, short-pointed or nearly obtuse, the margins above very closely serrate, dull green above and whitish green beneath: fls. small, in 2–5-fl. umbels, the pedicels slender: fr. nearly globular, purple-black, on slender sts. On sandy and rocky inland shores from E. Que. to Man. and south to the District of Columbia; common on sand-dunes along the Great Lakes.—The fr. is small and usually scarcely edible, the flesh being astringent. The species is common on dunes of the Great Lakes. It is in cult. as an ornamental plant, for which it is worthy, although it is much attacked by the twig-blight (caused by the fungus *Monilia*). There are reputed crosses between this species and native plums.

36. *cuneata*, Raf. (*P. pumila* var. *cuneata*, Bailey). Fig. 3230. Erect, 1–4 ft.: lvs. thin, oval, short-obovate or spatulate, strongly toothed, especially at apex: fls. larger. Bogs and cool woods and about lakes in the northern states, and in the mountains as far south as N. C.—Not in the trade, so far as known, and not promising horticulturally.

37. *Bésseyi*, Bailey (*P. pumila* var. *Bésseyi*, Waugh. *P. Rósebudii*, Reagan. *P. prunella*, Daniels). WESTERN SAND CHERRY. Figs. 3231, 3232. Known from *P. pumila* by its more prostrate habit, lvs. spreading (more erect in *P. pumila*), broad and thick, usually elliptic, elliptic-oval, or elliptic-lanceolate: stipules on strong shoots, large and green, serrate: fr. nearly or quite twice larger, on short stalks, usually sweet, in certain selected forms as much as $\frac{3}{4}$ in. diam. This is the sand cherry of the Plains and the W., ranging from Kans. to Man., and west to Wyo. and Colo. B.M. 8156.—The original of the Improved Rocky Mountain cherry, a plant grown for its large sweet fr. Large-fruited forms of this species are much prized on the Plains for pies and other cookery, and the species is promising horticulturally. Many hybrids with other species of *Prunus* have been secured by Hansen. The species is useful as a stock for certain other cherries, plums, and

3230. *Prunus cuneata* ($\times \frac{1}{2}$). No. 36.

even peaches for cold countries where the trees must be protected. See Hansen, Bull. No. 87, S. Dak. Exp. Sta. (1904), and subsequent bulletins.

cc. *lvs. usually serrate or crenate to the base, sometimes double-serrate: fr. red.* Nos. 39 and 40 are the dwarf or "flowering" cherries of gardens, often confused with the flowering almond (*P. triloba*) but distinguished by the longer pedicellate fls. which usually are not solitary from the bud.

38. *utahensis*, Dieck. UTAH HYBRID CHERRY. Apparently a hybrid of *P. angustifolia* var. *Watsonii* and *P. Besseyi*. A small tree-like bush: lvs. lance-elliptic to oblong-oval, short-pointed or nearly blunt, finely serrate, slightly conduplicate, glossy above and much reticulated beneath: fr. cherry-like, somewhat larger than that of *P. Besseyi* (about $\frac{5}{8}$ or $\frac{3}{4}$ in. diam.), of deep mahogany-color, with a thin plum-like bloom, a thin flesh and a relatively large cherry-like stone.—Appears to have been raised about 50–60 years ago from seed of *P. Besseyi* (*P. Watsonii* grew near) by J. E. Johnson, in Nebr. Mr. Johnson subsequently moved to Utah, whence the fr. was distributed. It has little value as a fr.-plant, but it is an attractive ornamental subject, both in fl. and fr.

39. *japonica*, Thunb. (*P. nana*, Hort., in part. *P. sinensis*, Hort., of Amer. gardens). Fig. 3233. Bushy plant, rarely over 5 ft. high: lvs. ovate, ovate-orbicular, or otherwise on the broad order (rarely as narrow as ovate-lanceolate) acuminate or even caudate, not at all inclined to be lobed, coarsely double-serrate or crenate, glabrous beneath or short-hairy on midrib and nerves: fls. in 2's and 3's, rose-colored or bluish, stalked (the stalks lengthening), appearing with the lvs.: fr. globular or short-oblong, $\frac{1}{2}$ in. diam., smooth and shining, wine-red. Cult. from Japan, but probably native to China. To what extent this species is cult. in this country is yet to be determined. It runs into several well-marked forms. Var. *eujaponica*, Koehne. Branches erect and virgate; lvs. short and broad-acuminate, the primary teeth short and obtuse but not truly triangular; blade beneath glabrous at maturity or lightly hairy on rib and nerves, rounded at base: fls. simple (not double). Var. *gracillima*, Koehne. Branches wide-spreading, the branchlets very slender and somewhat deflexed: lvs. long- and narrow-caudate, mostly cordate

3231. *Prunus Besseyi* ($\times \frac{1}{2}$). No. 37.

at base, the primary teeth longer and more acute, and exactly triangular: fls. simple (not double), white or rose. Var. *Thunbergii*, Koehne. Mature lvs. glabrous beneath: lvs. long- and narrow-acuminate, the teeth truly triangular: fls. pale rose, on pedicels about $\frac{1}{2}$ in. long; petals $\frac{1}{2}$ in. long, the stamens shorter; style sparsely pilose at base. Var. *Engleri*, Koehne. Differs from var. *Thunbergii* in the mature lvs. being short-hairy and the midrib and nerves beneath and pedicels twice or more as long (becoming $\frac{3}{4}$ in. long in fr.): petals $\frac{1}{2}$ in. or more long, pale flesh-color; stamens $\frac{1}{4}$ – $\frac{1}{2}$ in. long; style glabrous or hairy at base. Var. *Kerii*, Koehne. Fls. semi-double, the petals numerous; ovaries usually 2: lvs. glabrous beneath. B.R. 27 and

R.H. 1852: 301 (both as *P. japonica*). B.M. 2176 (as *Amygdalus pumila*).

40. *glandulosa*, Thunb. Fig. 3227. Long confused with *P. japonica*, but differing markedly in the foliage: lvs. ovate-oblong, oblong, oblong-lanceolate, or otherwise on the narrow order, little or not at all acuminate

3232. Western sand cherry.—*Prunus Besseyi* ($\times \frac{1}{2}$). No. 37.

but gradually tapering, widest at or below the middle, closely serrulate or crenate-serrate, sometimes in part somewhat doubly serrate, glabrous beneath or slightly hairy along the midrib: fls. about 2 from the bud, slender-stalked (pedicels about $\frac{3}{4}$ in. long at anthesis), bluish, pink or white. China. B. M. 8260 (as *P. japonica*).—*P. glandulosa*, Torr. & Gray (*Amygdalus glandulosa*, Hook.), the "wild peach," a very different plant on prairies in Texas, promising, must take the name *P. texana*, Dietr. (*P. Hookeri*, Schneid.). The *P. glandulosa*, Thunb., assumes many forms. Var. *glabra*, Koehne. Fls. simple or double, white or rose, with glabrous pedicel and style: stipules persistent: lf.-blade glabrous both sides or hairy in the axils of veins beneath: young branchlets pulverulent at base. B.R. 1801, (as *P. japonica*, white-fl.). I.H. 5:183 (as *P. japonica flore albo-plena*). Var. *Purdomii*, Koehne, probably not cult.: differs from var. *glabra* in petioles and pedicels being puberulent: fls. simple; style glabrous. Var. *trichostyla*, Koehne. Fls. single or double, white or rose, the pedicels glabrous or puberulent, style pilose at base: stipules persistent: young branchlets glabrous or pulverulent: fls. white, about $\frac{3}{4}$ in. across. Frequent in cult.; it has been described under such names as *Prunus sinensis*, *P. japonica flore-plena*, and *Cerasus japonica*. The growth is wiry and erect, the branches glossy and purple-brown. Var. *salicifolia*, Koehne. Stipules deciduous: fls. mostly only 1 from a bud: branches erect and virgate, to 3 ft. high, glabrous: lf.-blade narrow, or linear-elliptic, acuminate or acute, simply or doubly serrate. Liao-tung Peninsula; probably not cult.—*P. glandulosa* is a common "flowering almond" of American gardens. It is cult. chiefly in two forms, the double white (var. *glabra forma albiplena*, Koehne), and the double pink (var. *trichostyla forma sinensis*, Koehne). What other botanical forms may be in cult. as flowering almond needs to be determined.

41. *humilis*, Bunge. Erect shrub, 1–4 ft. high, with slender dark brown branches: lvs. 2 in. or less long, elliptic-ovate, somewhat acute, short-petioled, serrulate, bright green above, lighter colored beneath, the linear stipules glandular-ciliate: fls. solitary or in pairs, broadest above the middle, short-pedicelled and short-pedicelled, white with red-based petals, $\frac{1}{2}$ in. diam., appearing with the lvs.; calyx-lobes oblong, obtuse, and ciliate, as long as the tube; petals twice exceeding calyx-lobes or sepals, orbicular and crenulate: fr. $\frac{1}{2}$ in. long, ovoid-globose, red. N. China. B.M. 7335.

3233. Leaf of *Prunus japonica* ($\times 1$). No. 39.

BB. *Sepals or calyx-lobes erect or erect-spreading; fls. mostly 1 or 2, pedicels short or none.*

42. tomentosa, Thunb. (*Cerasus tomentosa*, Wall.). Small compact but wide-spreading tree, or in Amer. a tree-like bush, the young growths pubescent-tomentose: branches close-jointed, causing the lvs. and fls. to be numerous: lvs. broad-oval to short-obovate, short-stalked, abruptly contracted into a short point, the margins incisely and sometimes unequally serrate, dull and rugose above, densely pubescent-tomentose beneath: fls. white as to petals but with bright red calyx and pedicel, small, sessile, usually 1 or 2 at a joint, appearing just before the lvs. or as the lvs. begin to unfold, from pink buds: fr. light red, globular, the size of a very small cherry, sessile or very short-stalked, sparsely hairy, eaten in Japan. N. China and Manchuria. B.M. 8196. A.G. 12:77. G. F. 5:581.—A worthy hardy small tree, making a very dense top, and quite unlike most other cherries in appearance. On floral characters the species gives rise to many forms, 2 or 3 of which are in cult.

Var. Spaethiana, Koehne. Fls. white, appearing with the lvs., and somewhat scattered on the branches, the petals about $\frac{1}{2}$ in. broad; calyx-lobes or sepals somewhat longer than the tube. **Var. Graebneriana**, Koehne, differs from var. *Spaethiana* in the large fls. (petals $\frac{1}{2}$ in. broad) which are crowded, and calyx-lobes about equaling the short-tubular calyx-tube. **Var. endotricha**, Koehne. Lvs. elliptic or oblong, 1–2 in. long, the petiole very short: fls. white, very abundant: fr. about $\frac{1}{2}$ in. long and nearly as broad, dark red, sparingly pilose.—*P. tomentosa* is hardy even in the Dakotas, and improved fruit-bearing races of importance are likely to arise.

43. incana, Stev. (*Cerasus incana*, Spach. *Amigdalus incana*, Pall. *A. nana* var. *incana*, Loud.). Slender-twigged shrub of medium size (3–5 ft.): lvs. small, the petiole short and soft-hairy and glandless or bearing glands at the top, the blade about 2 in. long (1–2½ in.), ovate-oblong, elliptic or lance-elliptic, short-pointed or obtuse, finely sharp-toothed, white-tomentose beneath: fls. mostly in 2's, appearing with the lvs. or just in advance of them, light rose-color, about $\frac{1}{2}$ in. across, the petals emarginate, the pedicels not exceeding the bud-scales: fr. bright red, the size of a pea, smooth, juicy. S. E. Eu. and W. Asia. R.H. 1853:281. B.R. 25:58. Gt. 44, p. 243 (lf.).—**P. Maureri**, Zabel, is a hybrid of *P. incana* and *P. pumila*.

44. prostrata, Labill. (*Cerasus prostrata*, Loisel.). Crooked or scraggy shrub to 6 ft., with tomentose somewhat erect or spreading branches: lvs. 1 in. or less long, short-ovate or ovate-orbicular, rarely lanceolate, obtuse, serrate, mostly very white beneath, the petiole short and glandless: fls. mostly single (sometimes fascicled), rose-red, appearing with the lvs., nearly sessile; calyx-tube about $\frac{1}{4}$ in. long, cylindric, pubescent or glabrous, the lobes oblong, obtuse, and entire; petals exceeding calyx-lobes or sepals, very broad: fr. $\frac{1}{2}$ in. diam., ovoid or nearly globular, dry, red-purple. S. E. Eu. and S. W. Asia.

45. microcarpa, C. A. Mey. (*Cerasus microcarpa*, Boiss. *P. diffusa*, Schneid.). Shrub of variable habit, 7 ft. or less high, bark dark brown or tawny, branches usually pubescent when young: lvs. small (about 1 in. or less long), broad-ovate or ovate-elliptic or lance-oblong, somewhat acute, serrate, glabrous or somewhat pubescent; petioles very short, thinly pubescent: fls. 2 or few together, about $\frac{1}{2}$ in. across,

pale rose or white, appearing with the lvs. or just preceding them, on pedicels $\frac{1}{2}$ in. or less long; calyx-tube reddish outside. the lobes very short and ovate and ciliate; petals obovate, $\frac{1}{4}$ in. or less long: fr. ovoid, about $\frac{1}{4}$ in. long, red or yellowish. Asia Minor, Persia. B.M. 8360.

AA. *Fls. from a single bud above the lf.-scale, rather than from 2 lateral buds that spring from the scales at the base of the central bud as in A (where the buds are therefore typically in 3's, whereas in AA they are placed singly on the axial growth of the previous year or are clustered on spurs): infl. umbellate and sessile or branching and peduncled: petiole usually long, or at least prominent: plant a tree or tree-like in most species. (Typocerasus.)*

B. *Sepals or calyx-lobes reflexed.*

c. *Lvs. roundish,—nearly as broad as long: fl.-clusters on the ends of the branchlets.*

46. Mahaleb, Linn. (*Cerasus Mahaleb*, Mill. *Prunus odorata*, Lam. *Padus Mahaleb*, Borkh.). **MAHALEB CHERRY**. **St. Lucie Cherry**. Small slender tree with hard glabrous branchlets: lvs. 2–3 in. long, light green, round-ovate to orbicular, abruptly very short-pointed, often subcordate at base, the margins closely callous-serrate: fls. small, fragrant, white, in small terminal umbels in May and June (in N. Y.), appearing when the tree is in nearly full leaf: fr. very small, dark red, not edible. Cent. and S. Eu. and the Caucasus.—Extensively imported for cherry-tree stocks, and frequently run wild. There are several cult. forms, as: var. *chrysocarpa*, Hort., with yellow fr. (Gn. 62, p. 181); var. *albo-marginata*, Dipp., with white-edged lvs.; var. *variegata*, Hort., with variegated foliage; var. *pendula*, Hort., with weeping or drooping branches (G.M. 44:210); var. *globosa*, Dieck, with rounded head; var. *compacta*, Hort., with compact condensed head; var. *monstrosa*, Kirchn., has very short and thick branches and branchlets; var. *Cupaniana*, Fiori & Paol. (*P. Cupaniana*, Guss.), is smaller than the type: lvs. much smaller ($\frac{1}{2}$ to about 1 in. long): peduncles

3235. *Prunus pennsylvanica* ($\times \frac{1}{2}$). No. 49.

short, 3–6-fld.: fls. smaller. Sicily. **Var. transilvanica**, Schur. Fls. small, numerous in the cluster; sepals reflexed. Transylvania.

cc. *Lvs. distinctly longer than broad: fl.-clusters mostly lateral.*

d. *Fl.-clusters branching and leafy (with prominently broad lf.-like bracts).*

47. Maximowiczii, Rupr. Tree, to 50 ft., with horizontal branches: lvs. obovate or elliptic-obovate, coarsely double-toothed, prominently veined, glabrous, rather short-acuminate, the petiole hairy and glandless and about $\frac{1}{2}$ in. long: fls. white, about $\frac{3}{4}$ in. across, long-pedicelled, appearing with the full foliage on slender open leafy-bracted peduncled clusters, the stalks, broad serrate bracts, and calyx hairy: fr. size of small pea, black. Manchuria, Korea, Saghalin, Japan.—A distinct and attractive species.

DD. Fl.-cluster a small umbel, very short-pedunculate.

48. *pilosiuscula*, Koehne. Shrub, or tree to 40 ft., and a trunk to 16 in. diam.: lvs. obovate or obovate-oblong, some specimens broader, base mostly rounded or emarginate, more or less acuminate, very strongly and often somewhat incisely doubly or simply serrate, the teeth acuminate and glandless or very nearly so, mostly glabrous above and hairy or glabrous beneath; petiole $\frac{1}{4}$ – $\frac{1}{2}$ in. long, slightly hairy or glabrous, with 2 glands at apex or on the base of the blade: fls. with or just preceding the lvs., pink, solitary or mostly 2 or 3 together, the bracts oblong to rotundate and glandular-serrate, persistent, the peduncle very short to $\frac{1}{2}$ in. long, the pedicels $\frac{1}{2}$ to more than 1 in. across; calyx-tube glabrous; lobes triangular, obtuse or acute, glabrous or at the apex sparsely ciliate; petals about $\frac{1}{2}$ in. long, oval: fr. oblong, red. Cent. and W. China. Var. *mèdia*, Koehne, differs in having hairs on the midrib and nerves of the lf. underneath.

DDD. Fl.-clusters sessile, umbellate, not branching.

E. Teeth of lvs. very short or small: native bird cherries, bearing very small white fls. on slender pedicels in naked small lateral umbels, and a profusion of very small red or black frs.

49. *pennsylvànica*, Linn. (*Cérâsus pennsylvànica*, Loisel. *C. boreâlis*, Michx. *Prunus boreâlis*, Poir. *P. persicifolia*, Desf. *Cérâsus persicifolia*, Loisel.). COMMON WILD BIRD or PIN CHERRY. Fig. 3235. Shallow-rooted tree with slender red-barked branches, 25–40 ft. high and sometimes $1\frac{1}{2}$ ft. in diam. of trunk: lvs. oblong-lanceolate-acuminate, light green and rather thin, closely sharp-serrate: fls. small, white, slender-stalked, appearing with the lvs., in 2's or 3's: fr. the size of a pea, light cherry-red, the flesh thin and sour and somewhat puckery; stone oblong. Sandy and rocky lands, Newfoundland to Brit. Col., and south in the mountains to Colo. and N. C. S.S. 4:156. B.M. 8486. —Where the tree grows naturally, it often sprouts inveterately and becomes a nuisance. When bruised, the wood has a strong peach-like odor. It is an interesting ornamental tree, however. In poor soils, it is often little more than a bush. On large trunks the bark tends to peel in transverse strips. Var. *saximontâna*, Rehd., of the Rocky Mt. region, is shrubby in growth, with smaller and broader pale green lvs. and few-fl. sessile umbels.

50. *emarginâta*, Walp. (*Cérâsus emarginâta*, Douglas). Shrub, 3–10 ft. high, sometimes a small tree, forming dense thickets: lvs. oblong-ovate or oblanceolate, mostly obtuse, closely serrate, often somewhat pubescent beneath: fls. tinged green, appearing with the lvs.

in 6–12-ft. glabrous or pubescent corymbs: fr. larger than that of *P. pennsylvànica*, almost black when ripe, the flesh thin and bitter; stone ovoid. Mountains, Brit. Col. to Calif. S.S. 4:157.—Sometimes offered as an ornamental tree.

51. *môllis*, Walp. (*P. emarginâta* var. *môllis*, Brew. *Cérâsus môllis*, Douglas). Small tree, reaching 30–50 ft., straight and graceful, with reddish cherry-like bark: young growth soft-pubescent: lvs. 1–3 in. long, obovate to oblong or oblanceolate, mostly acute, serrate, nearly or quite glabrous above, pubescent underneath, the stipules narrow and lacinate: fls. white, in 5–10-fl. clusters; calyx-lobes oblong, obtuse, and entire, becoming reflexed, much shorter than the tube; petals obovate, about 2 lines ($\frac{1}{16}$ in.) long: fr. $\frac{1}{2}$ in. or less long, bright red, very bitter; stone wrinkled, keeled on one edge. Woods, Brit. Col. to Calif.

EE. Teeth of lvs. mostly prominent (exception in No. 52).

52. *fruticôsa*, Pall. (*P. Cérâsus* var. *pùmila*, Linn., not *P. pùmila*, Linn., *P. Chamæcérâsus*, Jacq. *P. pùmila*, Hort. *P. intermèdia*, Poir. *Cérâsus Chamæcérâsus*, Loisel. *C. humilis*, Hort. *Cérâsus sibirica*, Hort.). DWARF CHERRY, or GROUND CHERRY, of Eu. Spreading bush, 2–4 ft. high, with slender glabrous branchlets: lvs. varying from obovate to oblanceolate and lanceolate, the apex acuminate or sometimes almost obtuse, closely serrulate, thickish, shining above, the petiole short: fls. white, in nearly or quite sessile umbels: fr. small, globular, purple-red, very sour. Highlands and mountains of Germany, Austria-Hungary, and S. Russia.—*P. éminens*, Beck, is a hybrid of *P. fruticôsa* and *P. Cérâsus*.

Var. *péndula*, Dipp. (*Prunus* and *Cérâsus japonica péndula*, Hort.), is a most ornamental form with drooping branches, excellent for top-working on standard stocks (Fig. 3236). G.W. 10, p. 511. This is

sometimes confounded with *P. semperflorens* (No. 53), but is distinguished at once by its foliage, its early blooming, its fls. in clusters, and its dwarf habit. This is the form of *P. fruticôsa* chiefly known in this country. A similar pendulous form, but with larger and more crenate-serrate lvs., is known as *P. reflêxa*, Hort.; perhaps a hybrid of *P. fruticôsa* and *P. semperflorens*. Var. *variegâta*, Hort., has lvs. marked with yellowish white.

53. *Cérâsus*, Linn. (*Cérâsus vulgâris*, Mill. *C. caproniâna*, DC. *P. austèra*, Ehrh.). SOUR, PIE, or MORELLO CHERRY. Figs. 907, 910, Vol. II. Rather low round-headed tree with gray bark and no central leader (compare Figs. 907 and 906, Vol. II), suckering from the root: lvs. ovate-obovate or short-ovate, abruptly short-pointed, stiff and parchment-like and

3236. Weeping dwarf cherry stock. One of the best of the and known under several *fruticôsa* var. *péndula*. (No. 52.)

of Europe, grafted on Morello small ornamental species, names in nurseries.—*Prunus*

more or less glossy above, light or gray-green: fls. in small clusters from lateral buds mostly in advance of the lvs., the scales of the fl.-buds small; calyx-tube glabrous, little if any constricted at top, the lobes deflexed and crenate, obtuse; fr. roundish or depressed-globular, red, soft-fleshed, acid; stone globular. Native to Asia

3237. *Prunus Cerasus* var. *sempervlorens* ($\times \frac{1}{2}$). No. 53.

Minor and perhaps to S. E. Eu.—*P. Cerasus* is the common pie cherry of old yards. It escapes into fence-rows and other waste places, forming dense thickets, as does the plum. It sprouts from the root. The various Morellos belong here; also the Montmorency, Louis Phillippe, and others. There are at least 2 well-marked groups of these pomological cherries—those with uncolored juice (Amarells, the *Prunus acida* of some), and those with colored juice (Morellos or Griottes). To the former group belong the Montmorency, Early Richmond, and several early varieties. Many botanical Latin names have been applied in this group of cherries, and the interpretation of the relative systematic standing of the different forms is much confused. For our purpose, the leading forms may be ranged as follows: Var. *frutescens*, Schneid. (*P. acida*, Koch), comprising the bushy small-fruited spontaneous or run-wild forms. Var. *typica*, Schneid., comprising the tree-like cult. forms of many kinds. To this latter group or class belong not only the orchard sour cherries, but also such ornamental varieties or groups as follow. Var. *Rhéxii*, Kirchn. (var. *ranunculiflora*, Hort.). Fls. double, white. F.S. 17:1805. Gn. 78, p. 228. Var. *persiciflora*, Koch. Fls. full, double, light rose or pink. Var. *variegata*, Hort. Lvs. variegated with yellow and dull white. Var. *aucubæfolia*, Dipp. Lvs. spotted with yellow. Var. *cucullata*, Kirchn. Lvs. puckered or blistered. Var. *globosa*, Spaeth. Low round-headed small-lvd. bush.

By some authors, the species is divided into the *Eucerasus* (i.e. true *Cerasus*) group, comprising the tree-form kinds, with strong branches erect or ascending or perhaps somewhat drooping with age, lvs. and

petioles with or without glands, large or good-sized fr. with globular or only rarely ovoid stone; and the *Acida* group (*P. acida*, Koch, not Ehrh.), comprising the more bush-like forms (as the *Ostheim*), with more drooping or hanging branches, short gland-bearing petioles, and smaller globular fr. with ovoid stone about $\frac{1}{2}$ in. or less long. To this latter race probably belong several forms more or less cult. for ornament, as *P. acida* var. *dumosa*, Hort., a bushy form blooming profusely when young. Gn. 78, p. 201.

Var. *sempervlorens*, Loud. (*P. semperflorens*, Ehrh. *Cerasus semperflorens*, DC.). EVERBLOOMING CHERRY. ALL-SAINTS' CHERRY. Figs. 3237, 3238. A horticultural state of *P. Cerasus* var. *typica*: small tree or a bush, usually top-worked on other stock, with a straggling or drooping habit, the slender twigs glabrous: lvs. oval to oblong-ovate, short-pointed (or acuminate on the strong shoots), irregularly dentate, rather hard and firm in texture: fls. white, on long axillary and terminal peduncles from May till September: fr. like a small pie cherry, but mostly longer-stalked and smaller, dark red.—Its habit of blooming all summer makes it a desirable ornamental subject. The lvs. resemble those of *P. Cerasus*, except that they are smaller. Known in France as *Cerisier de la Toussaint* ("All-Saints' cherry") and in Germany as *Allerheiligen Kirsche*. There is a form with yellow-variegated lvs. The Everblooming cherry appears to be very little planted in this country, but it is an interesting form.

54. *avium*, Linn. (*Prunus Cerasus* var. *avium*, Linn. *Cerasus avium*, Moench. *C. nigra*, Mill. *C. dulcis*, Gaertn.). SWEET CHERRY. MAZZARD. Figs. 3239; also Figs. 906, 908, 909, Vol. II. Tall robust tree with red-brown bark, sometimes 100 ft. high, the young trees with a strong central leader and pyramidal growth, the old seedling trees sometimes becoming 2 ft. and more in diam. (see Fig. 908, Vol. II): lvs. generally oblong-ovate and gradually taper-pointed, dull and soft in color and texture, hanging as if limp on the young growths: fls. in dense clusters on lateral spurs and appearing with the hairy strongly conduplicate young lvs., the scales of the fl.-buds large and persistent for a time; calyx-tube glabrous, constricted near the top, the lobes reflexed and entire: fr. globular, depressed-globular or heart-like, mostly sweet, yellow or red. Eu. and W. Asia.—The parent species of the many sweet cherries (and also of the May Duke class), and now run wild in many parts of the E. The run-wild and common seedling forms, with small frs., are known under the general name of Mazzard cherries.

3238. *Prunus Cerasus* var. *sempervlorens*. (Spray $\times \frac{1}{2}$)

Mazzard stocks, mostly imported, are used as stocks for cherries, although Mahaleb is more popular with propagators because (like the Myrobalan plum) it is easier and cheaper to grow, runs more uniform and is capable of being budded through a long season.

There are many ornamental forms of the *P. avium*, as: var. *pyramidalis*, Hort., tree making a pyramidal crown; var. *péndula*, Hort., with drooping branches (Gn. 59, p. 267); var. *variegata*, Hort., with yellow and dull white markings on the foliage; var. *asplenifolia*, Kirchn., with deeply toothed and cut lvs.; var. *plèna*, Hort., with double fls. (G.M. 53:9. G.W. 6, p. 329. Gn. 78, p. 242); var. *salicifolia*, Dipp., with very narrow lvs. *P. Fontanesiana*, Schneid. (*Cerasus Fontanesiana*, Spach. *P. græca*, Desf.), is probably a hybrid of *P. avium* × *P. Mahaleb*, like *P. avium* in habit: young branchlets pubescent; lvs. about 4 in. long, differing from those of *P. avium* in the more crenate gland-tipped serrations; does not produce fr. To *P. avium* are to be referred such garden names as *P. angustifolia*, *P. heterophylla*, and others.

3239. *Prunus avium* (× $\frac{1}{2}$). No. 54.

Var. *Juliana*, Bailey (*Prunus Cerasus* var. *Juliana*, Linn. *Cerasus Juliana*, DC.). HEART or GEAN CHERRIES. Fr. heart-shaped, with soft flesh, as in the varieties Governor Wood, Black Tartarian, Black Eagle. These are the *Guigniers* and *Heaumiers* of the French. A weeping form is known as *P. Juliana* var. *pendula*.

Var. *regalis*, Bailey (*C. regalis*, Poit. & Turp.). DUKE CHERRIES. Differ from the Heart cherries in having an acid flesh (and for that reason often erroneously referred to *P. Cerasus*). May Duke is the leading representative. Said by Hedrick ("Cherries of New York") to be "unquestionably hybrids between the Sweet cherry and Sour cherry," *P. avium* and *P. Cerasus*.

Var. *duracina*, Bailey (*Prunus Cerasus* var. *duracina*, Linn. *C. duracina*, DC. *C. Bigarèlla*, Roem.). BIGARREAU or HARD-FLESHED CHERRIES. Distinguished by the firm breaking flesh of the fr., which is mostly of light color. Here belong the Windsor, Yellowish Spanish, Napoleon.

Var. *decumana*, Koch (*C. decumana*, Delann. *P. macrophylla*, Poir. *P. nicotianæfolia*, Thoms.). Lvs. very large (sometimes nearly 1 ft. long and 4-6 in. broad), somewhat heart-shaped. Grown for ornament.

BB. Sepals or calyx-lobes erect-spreading.

C. Floral involucre (at base of infl.) large, about $\frac{1}{2}$ in. long or more; lvs. not lobulate or incised-double-serrate.

D. Fruiting pedicel not thickened, or only very gradually so at apex.

E. Calyx-tube acute at base, narrowly tubular or turbinate-tubular; fr. black. This group comprises the famous Japanese flowering cherries of midspring and later.

55. *serrulata*, Lindl. (*Cerasus serrulata*, Don. *C. serratifolia*, Carr. *Prunus Pseudo-Cerasus*, Hort., not Lindl. *P. mutabilis*, Miyoshi, in part.) JAPANESE FLOWERING CHERRY. Large tree, long in cult., but, like other Japanese and Chinese cherries, little known in Amer.: lvs. large (3-6 in. long and 2 in. or more broad), oval, ovate to obovate, abruptly long-acuminate, glabrous, glaucescent beneath, deep green, the prominent teeth short-aristate; petiole glabrous, glandless or with 1 or 2 small glands near apex; fls. white, not fragrant, semi-double, in a large glabrous infl., appearing with

lvs. or just preceding them, in 3-5-fl. clusters on short or long peduncles, the bracts large, fimbriate, the pedicels to 1 in. long; calyx-tube glabrous, the ovate-acute lobes or sepals mostly exceeding the tube; style glabrous; fr. size of small pea, black. China, Japan, Korea. G.C. III. 7:609; 19:467. Gn. 56:300. A.G. 12:399.—This showy species occurs in cult. in many forms, with fls. whitish or pink and otherwise variable, often under the name of *P. Pseudo-Cerasus*. A very double pink and rather small-fl. form is forma *rosea* Wilson (f. *Shidare-Sakura*, Koehne). Var. *spontanea*, Wilson (f. *Shidare-Sakura*, Koehne). Var. *spontanea*, Wilson, is a wild form in China, Korea, and Japan, with single white or pink fls. about $\frac{1}{2}$ in. across, and lvs. greenish brown to reddish brown when unfolding. This form is also cult. in the Orient. It makes a tree to 75 ft. high and 12 ft. in girth. Formæ of this variety are f. *humilis*, Wilson, bush or small tree with pale fls. and rather glaucous under surface of lvs., the peduncle elongated, cult. in Japan; f. *Kosioyama*, Wilson, fls. single, pinkish, lvs. slightly hairy on upper surface of midrib, cult. in Japan and intro. in this country; f. *præcox*, Wilson, fls. single and rather small, pale pink, blooming in late winter in Japan, and also intro. in this country. Var. *pubescens*, Wilson (*P. tenuiflora*, *P. Leveilléana*, *P. mesadenia*, *P. Veitchii*, *P. verecunda*, Koehne. *P. quelpaertensis*, Nakai). Lvs. pale green below and more or less sparsely pubescent, the petiole somewhat bearded, and pedicels pubescent; fls. single, white or pink. China, Korea, Japan; said by Wilson to have the widest distribution of any Japanese cherry, and it is there cult., and forms of it have been intro. in this country. Wilson recognizes the following formæ of this variety: *sacra* (*Meigetsu*), lvs. slightly villous above and pale beneath, the fls. single, white changing to pale pink; *Shibayama*, fls. single and pink, of little horticultural value; *Tanzanfukun*, first described under this species, is now referred by Wilson to *P. yedoensis*.

Var. *sachalinensis*, Makino (*P. Pseudo-Cerasus* var. *sachalinensis*, F. Schmidt. *P. sachalinensis*, Koidz. *P. Sargentii*, Rehd. *P. floribunda*, Koehne). Fig. 3240. Large tree attaining a height, in its native places, of 60-80 ft. with trunk 9-13 ft. in girth and head 30-50

3240. *Prunus serrulata* var. *sachalinensis* (× $\frac{1}{2}$). No. 55.

ft. across, producing valuable wood: bark reddish and lustrous; older branches chestnut-brown. lvs. large, oval or ovate, abruptly slenderly acuminate, coarsely sharp-toothed, glabrous and lustrous, turning to crimson and yellow in autumn, mostly with glands on petiole or base of blade: fls. 2-4, very showy, rose-pink, appearing before the lvs., simple (not double), light rose-color, about $1\frac{1}{2}$ in. across, the pedicels slender, to $1\frac{1}{2}$ in. long and with glandular serrate bracts or involucre; petals obovate and emarginate; calyx-lobes ovate-lanceolate, acute, entire; stamens 20-25: fr. size of pea, bright red and becoming black and shining at maturity. June. N. Japan, Saghalin, Korea. B.M. 8411. G.C. III. 19:517; 55:346. G.F. 10:463 (shown reduced in Fig. 3240).—A tree of great ornamental value, hardy in N. Y. and Mass., bearing profusely of its handsome broad fls. From *P. serrulata* it is distinguished by its broader more coarsely serrate lvs., of which the serratures are scarcely pointed: lvs. glabrous, bronze-metallic green when unfolding, becoming yellow, orange, and crimson in autumn; serration simple and double on same lf., the teeth gland-tipped and mucronate or aristate: fls. appearing with the lvs. or slightly in advance, $\frac{1}{2}$ - $1\frac{1}{4}$ in. across, rose, pink, or nearly white. The forms of var. *sachalinensis* comprise some of the hardiest and best of the flowering cherries of Cent. and N. Japan. Of this important and very worthy variety, the following formæ are recognized by Wilson, most of which have been intro. into N. Amer. recently and all of which are named flowering cherries of Japan: *Benden*, pale pink single, or nearly single fls., of small horticultural value; *Hakkasan*, fls. pale pink, single or nearly so, of little value; *albo-rosea* (*P. Pseudo-Cerasus*, var. *Shirofugen*, Spaeth), fls. pink in bud and changing to white as they expand, bearing 2 leafy green carpels in the center, handsome; *Fugenzo* (*P. Pseudo-Cerasus*, G.C. III. 19:517. *P. Pseudo-Cerasus* var. *James Veitch*, Gt. 51:497. *P. serrulata* f. *Veitchiana*, Koehne), one of the handsomest and known in cult. as James H. Veitch, with rose-pink fls. bearing 2 leafy carpels in center; *Hisakura*, fls. pale pink, double, one of the handsomest; *Horinji* (*Cerasus Juliàna flore roseo pleno*, Carr. R.H. 1874, p. 20. *C. Caproniàna flore roseo pleno*, Van Houtte. F.S. 21:2238), fls. in clusters, pale pink and semi-double; *fasciculata* (*Itokukuri*), fls. double pink, clustered at ends of shoots; *Kirin*, late-flowering, with large very double rose-colored fls., one of the best; *homógena* (*Kokonaye*), fls. pink, long-pedicelled and usually short-peduncled, double or semi-double, pink; *Masuyama*, a fine form with double rose-pink fls.; *Ohnanden*, a fine form with rose-pink double or semi-double fls.; *Sekiyama*, late, with large double rich rose-colored fls., thought by Wilson to be "the handsomest of all Japanese double-fl'd. cherries;" *superba* (*Shogetsu*), rather late, good, very large, double, pale pink, long-pedicelled; *Shujaku*, fls. borne in great profusion, double, rose-pink; *spiràlis* (*Udzuzakura*), a good form producing pink double fls. freely near ends of branches, with short peduncle and long pedicels.

Prunus Pseudo-Cerasus, Lindl. (*P. involucrata*, Koehne), with which *P. serrulata* and other Japanese flowering cherries have been confused, is an entirely different species. It is not hardy in the northern states, and apparently is not in cult. in this country except perhaps under test in Calif. or elsewhere. It belongs to another subsection of the genus, more nearly allied to *P. canescens* and *P. lobulata*, described under Nos. 65 and 66. It is grown in China and also in Japan for its edible red subglobose apiculate fr., which is about $\frac{1}{2}$ in. or less in diam.: small tree, to 25 ft., the shoots pale gray to purplish and sparsely pubescent when young: lvs. sparsely pubescent but glabrous above at maturity, ovate to broad-ovate, secondary veins few, acuminate, rounded at base, doubly serrate with broadly triangular teeth: calyx-tube or cupula broadly obconic and

pubescent: fls. white, 2-5 in a cluster, 1 in. across; style glabrous. Wilson states that "as a fruit tree it does not compare in value with the European varieties derived from *P. Cerasus* and *P. avium*."

56. *Lannesiana*, Wilson (*Cerasus Lannesiana*, Carr. *P. serrulata Lannesiana*, Koehne. *P. Pseudo-Cerasus* var. *hortensis*, Maxim. in part). Fig. 3241. Differs from *P. serrulata* in its pink fragrant fls. (white in some of the formæ), teeth of lvs. long-aristate (rather than short-aristate), bark pale gray rather than dark chestnut-brown: lvs. unfolding green or slightly reddish, pale green beneath: calyx-tube or cupula campanulate, glabrous. Japan. B.M. 8012 and G.C. III. 19:466 (both as *P. Pseudo-Cerasus*). R.H. 1872, p. 198 (note); 1873:351. Forma *albida*, Wilson (*P. serrulata* f. *albida* and *speciosa*, Koehne. *P. muábilis*, Miyoshi, in part), has single white fls. This form is considered by Wilson to be the parent of the cult. kind taken as the type of *P. Lannesiana* and "also of the greater number of the double-fl'd. Japanese cherries;" thought to be indigenous on island of Oshima. It makes a tree to 30 ft. or more tall, with thick spreading or somewhat ascending branches, with a pale gray bark which is smooth even on old trees: fls. pinkish in the bud, white when open, glabrous

3241. Japanese flowering cherry.—*Prunus Lannesiana* ($\times \frac{1}{2}$). No. 56.

throughout, either with the lvs. or preceding them, the peduncle usually $\frac{1}{2}$ -1 in. long but sometimes wanting: fr. ovoid, black, and shining.

Some of the cult. kinds of *P. Lannesiana* in Japan, many of which have recently been intro. into this country, are ranged by Wilson under the following formæ: *donarium* (*P. donarium*, Sieb.), fls. white and double, fragrant; *Fudanzakura*, a precocious form that blooms at almost any season, the single fls. white or nearly so, of little horticultural value; *Gozanomanioi*, fls. white, single, very fragrant; *Habutai*, fls. single, white, and fragrant, of minor value; *Minakami*, fls. very fragrant, white, single or nearly so; *Ohshibayama*, of minor value, the fls. white flushed pink, single or semi-double; *subfúsa* (*Sumizome*), one of the handsomest; with very large fragrant single or nearly single white fls. flushed pink; *cataráta* (*Takinioi*), fls. very fragrant, single, white; *Wasinowo*, fls. single, fragrant, white; *Amayadori*, excellent, botanically much like *P. serrulata* var. *sachalinensis*, with double fls. clustered at ends of branchlets, pale pink passing to white; *Hatazakura*, fls. semi-double, white tinged pink, the inner petals reduced and rudimentary, said by Wilson to be "a very beautiful cherry, with fls. suggestive of apple

blossoms;" *Horaian*, fls. white, semi-double; *Hosokawa*, "a pleasing form" with fls. single or semi-double, pure white, and fragrant; *affinis* (*Jonioi*), "A lovely plant with fls. of remarkable whiteness," very fragrant, single or semi-double; *Kokesimidsu*, of minor horticultural interest, the fls. single or semi-double, white suffused pale pink; *Kunrinjishirotae*, fls. white, fragrant, semi-double; *Miyako*, one of the best of the late-flowering forms, with fragrant double fls. white flushed pink; *Senriko*, beautiful form, with very large fragrant semi-double fls. pale pink passing to white; *Sirotae*, "the finest of all the double-fl. white cherries," the fls. large and fragrant and pure white; *Sobanzakura*, fls. double, white; *Surugadai-odora*, late-flowering, the fls. nearly white, semi-double, fragrant, pendulous on long slender pedicels; *Ariake*, "a very striking form," with very large and fragrant single or semi-double pale pink fls.; *excelsa* (*Banriko*), of minor horticultural value, with single fls. "pale washy pink;" *campanulata* (*Gijozakura*), pink, single or semi-double; *Kirigaya*, fls. fragrant, single, pale pink; *Kongosan*, of minor interest, with single pink fls.; *Mazakura*, "the cherry used by the Japanese for a stock on which to graft all the garden forms of *P. Lannesiana* and *P. serrulata*," with few white or pinkish fls.; *Ranzan*, "a very pleasing form," with single pink fls. on long slender pedicels; *Temari*, fls. congested near end of branchlets, pale pink, single and semi-double; *erecta* (*Amandagawa*), "a beautiful form and very distinct in its habit of growth," branches fastigate, the fls. fragrant, semi-double, pale pink; *Benitoranovo*, "a good form," with rose-pink semi-double fls. clustered near ends of branchlets; *Moutan* (*Botanzakura*), "one of the very best forms," bearing very large, pale pink, fragrant, semi-double fls.; *Gosiozakura*, fls. semi-double, pale pink; *amabilis* (*Higurashi*), "a good form," with slightly fragrant, double and semi-double, pale pink fls.; *Isezakura*, semi-double, fragrant, pink; *Mikurumakaisi*, double, pale rose; *Ochichima*, fls. large, double, pale pink; *Ogon*, "a very beautiful form, commonly cult. in the temple grounds at Kyoto," with fls. pale pink and semi-double; *Ojochin*, "one of the best forms," the very large fls. semi-double and pale pink; *versicolor* (*Yayakebono*), fls. very large, fragrant, semi-double, soft pink, very beautiful; *nobilis* (*Yedozakura*), resembles *P. serrulata* var. *sachalinensis*, "a fine cherry," with pink double clustered fls. of good size; *Gioiko*, semi-double fls., pale yellow with greenish stripes, free-flowering; *grandiflora*, "a very striking cherry," with profusion of large semi-double or double greenish yellow fls. (Gn. 76, p. 229, as *P. serrulata flore luteo pleno*. Gt. 52:1513 as *P. serrulata grandiflora*).

57. *Sieboldii*, Wittm. (*Cerasus Sieboldii*, Carr. *P. Pseudo-Cerasus* var. *Sieboldii*, Maxim. *Cerasus Wátereri*, Hort.). JAPANESE FLOWERING CHERRY Strong-growing tree, like a sweet cherry, producing showy pink double fls. with the lvs. or just in advance of them: lvs. oval or ovate, abruptly acuminate, rounded at base, densely soft-pilose beneath, the margins very sharply gland-serrate; petiole hairy, usually bearing 1 or 2 small glands at apex: fls. 1-1½ in. across, 2-4 on each short peduncle, the pedicels more or less pilose; calyx-tube sparsely hairy or nearly glabrous, the ovate rather obtuse entire lobes about equaling the tube; style hairy at base. Japan, China. Known only in double-fl. forms. R.H. 1866, p. 371. Gn. 33, p. 420. G.W. 16, p. 355. Gt. 51:1494a. A.G. 12:400, 401.—Wilson writes that in habit and general appearance this species strongly resembles *P. Lannesiana*, but is distinguished by the pubescent caudate-acuminate lvs. which are sharply and often obscurely doubly serrate with small teeth: fls. double or semi-double, normally pink and preceding the foliage; if the fls. precede the lvs. the peduncle is very short, when coetaneous with the foliage the peduncle is much elongated and the fls. may then be nearly or quite white.

58. *yedoensis*, Mats. (*P. paracerasus*, Koehne. *P. yedoensis* var. *nudiflora*, Koehne). Near *P. serrulata*, differing in the pedicels, style, and usually exterior of calyx being hairy; and near *P. Sieboldii*, differing in young lvs. pale green rather than bronzy, and calyx-lobes sharp-serrate rather than entire. From Japan, but wild specimens unknown.—A tree-like shrub or good-sized tree, with young growth hairy but becoming nearly or quite glabrous in autumn or the second year: lvs. obovate or broadly ovate-elliptic, 3-5 in. long, acuminate, strongly double-serrate with serratures acuminate and gland-tipped, glabrous above, hairy on midrib and veins beneath: fls. in a 3-6-fl. short-peduncled corymb or cluster, with narrowly spatulate bracts, the pedicels ½-1½ in. long and densely pilose; petals broad-ovate or suborbicular, about ½ in. long or a little more, deeply emarginate; stamens about 37-39. The fls. are slightly fragrant, in clusters of 2 to several, usually preceding the lvs. but sometimes coetaneous, white to pink. "This is the cherry," writes Wilson, "so generally planted in the parks, temple grounds, cemeteries, and streets of Tokyo. Its flowering is the occasion of a popular festival in the city of Tokyo. The oldest authentically known trees were planted only a little over 40 years ago, and the species was not recognized as distinct till 1901. To Wilson the species is strongly suggestive of a hybrid between *P. subhirtella* var. *ascendens* and the wild form of *P. Lannesiana*. It is hardy at the Arnold Arboretum. *Taizanfukun* (*P. fruticosa* f. *ambigua*, Miyoshi) is a form with young shoots and petioles pubescent, fls. borne near ends of shoots, moderately double and of medium size, pink.

EE. Calyx-tube obtuse at base, *campanulate* or *cylindrical*: fr. red to black.

F. Blossoms appearing before the lvs.: teeth of lvs. large, acute, acuminate, or setaceous-acuminate: stone nearly or quite smooth.

59. *Conradinae*, Koehne. Graceful tree, to 25 ft., with rather thin glabrous or canescent shoots and large foliage: lvs. obovate or obovate-oblong, rarely roundish ovate, 2-6 in. long and about half as wide, the base usually rounded or even subcordate, apex narrow-acuminate, double-serrate, the teeth gland-tipped, glabrous or becoming so above and below; petiole about ½ in. long, glabrous, mostly with 2 glands; stipules linear, glandular-fimbriate: fls. whitish or pink, before the lvs.; peduncle sometimes ½ in. long but usually very short; pedicels (mostly 2-4 in the umbel) ¼-¾ in. long, glabrous; calyx-tube glabrous; lobes or sepals erect-spreading or spreading, more or less ovate, entire; petals about ½ in. long and ½ in. broad, emarginate-bilobed; style glabrous: fr. ovoid, ⅓-½ in. long, red. Cent. China.

FF. Blossoms appearing with the lvs.: teeth of lvs. small or minute: stone prominently rugose.

60. *serrula*, Franch. Tall tree, with young branches thinly pubescent but becoming nearly or quite glabrous in autumn: lvs. lanceolate, 2-4 in. long, base rounded, apex acuminate, strongly but shortly double-serrate, the teeth slender and gland-tipped, soon glabrous above, hairy along rib and in nerve-axils beneath, at base usually with 3-5 glands; petiole ⅓-½ in. long, glabrous, purplish. Apparently known to cult. in the var. *tibética*, Koehne, which has smaller teeth on the lvs.: fls. white, usually in 3's: fr. ovoid or globular-ovoid, about ½ in. long, red. W. China.—Cult. abroad; hardy in Mass.

DD. Fruiting pedicel prominently thickened.

61. *cerasoides*, D. Don (*P. Puddum*, Roxbg. *Cerasus Puddum*, Wall. *C. Phoshia*, Hamilt.). A Himalayan representative of *P. Pseudo-Cerasus*, described by Hooker as a large tree of brilliant appearance in flower, glabrous except the puberulous young shoots, the rose-red or

white fls. solitary, fascicled, or umbelled, the calyx-tube narrowly campanulate and the petals obovate or linear-oblong; lvs. ovate-lanceolate or oblong-lanceolate, caudate-acuminate, sharply serrate, glabrous, 3-5 in. long, the petiole with 2-4 glands; fr. oblong or ellipsoid, obtuse at both ends, with scanty yellow or reddish acid flesh; stone bony and furrowed. Temp. Himalaya, 3,000-8,000 ft.—The name is catalogued in S. Calif., with the statement that the tree "blossoms in November and ripens its fruit in April." Hooker (Fl. Brit. India) places it with species having "flowers appearing before the leaves."

62. *campanulata*, Maxim. (*P. cerasoides* var. *campanulata*, Koidz.). Closely related to *P. cerasoides*: tree, to 25 ft.; lvs. ovate to elliptic-ovate, glabrous, usually doubly serrate, 3-5 in. long; fls. pendulous, campanulate, $\frac{3}{4}$ in. long, deep rose-colored; calyx purple; fr. ovoid, $\frac{3}{8}$ in. long, red. Formosa, probably Liu-kiu Isls., cult. in S. Japan. Gn. 56:300 (as *P. pendula*).—Very ornamental; not hardy N. A beautiful species as grown in Japan. The Himalayan species (*P. cerasoides*) has more coriaceous and more sharply toothed lvs. in which double serration is usually not so marked.

63. *rufa*, Steud. Small tree, to 20 ft., the young growth densely tomentose; lvs. elliptic-lanceolate or oblong-lanceolate, 1-4 in. long, narrowed to very short petiole, long-acuminate, glabrous or puberulent on rib or nerves above and beneath, very sharply glandular-serrate; petiole pubescent, glandless; stipules thread-like and lacinate; fls. pink, $\frac{1}{2}$ in. diam., solitary, paired or fascicled in the axils of previous year's growth, appearing with the lvs., the stalks longer than petiole; calyx-tube urn-shaped, glabrous, the lobes triangular and dentate; petals small and orbicular; fr. ellipsoidal, on lengthened stalks, fleshy, red. Nepal and Sikkim, 12,000 ft. altitude.—Recently cult. in England.

cc. *Floral involucre either small or the lvs. prominently lobulate or incised-double-serrate.*

D. *Lvs. shortly or rather deeply serrate: involucre small, $\frac{1}{2}$ to about $\frac{1}{2}$ in. long; fls. with the lvs. or preceding them, the umbels sessile or the peduncles $\frac{3}{8}$ in. or less long; fr. mostly black. The early spring-flowering cherries of Japan.*

64. *subhirtella*, Miq. (*P. Miqueliana*, Maxim. *P. Herinoquiiana* var. *ascendens*, Schneid.). Plant a large shrub or small forking tree, with erect branches; lvs. shorter and relatively broader than in var. *pendula* (blade about 2 in. long except on terminal shoots), oval or ovate, abruptly narrowed above and below, sharply and more or less doubly serrate, more hairy beneath and sometimes thinly short-hairy above, the glands small or wanting; fls. 1 in. across. Much cult. in Japan, but unknown wild; less known in this country than var. *pendula*, but perhaps more beautiful. B.M. 7508. G.C. III. 33:163; 53:285. Gn. 63, p. 177. G. 25:147; 31:283.—This is the spring cherry of Japan and said by Wilson to be "the most floriferous and perhaps the most delightful of all Japanese cherries." Appears to have been intro. into N. Amer. first in 1894 by the Arnold Arboretum. The fls. normally appear in advance of the lvs., varying in color from nearly white to pink; calyx reddish. Sometimes a few fls. appear in autumn. Wilson writes that in its typical form this species may be separated from its varieties in herbarium material by its usually smaller and more glabrous lvs. and by its very numerous fls. which have less hairy and more highly colored calyx-tube and sepals. In living trees, the species is marked by its small size and ascending branches.

Var. *pendula*, Tanaka (*Cerasus pendula*, Sieb. *C. itosakura*, Sieb. *Prunus itosakura*, Sieb. *P. pendula*, Maxim. *C. japonica* and var. *rosea*, Hort.). ROSE-BUD CHERRY. JAPANESE WEEPING ROSE-FLOWERED

CHERRY. Fig. 3242. Small tree, with drooping crooked branches; lvs. lance-elliptic to oblong-oval or oval on older shoots (blade 3-4 in. long), acuminate, mostly narrowed at base, sharp-serrate, usually with a pair of large glands at base of blade or on apex of petiole, glabrous above, thinly hairy on rib and veins underneath; fls. $\frac{3}{4}$ in. across, on long minutely pubescent stalks, in small clusters, from lateral buds before the lvs. appear, rose-pink, the petals notched at the tip, the calyx-tube funneliform and red; style hairy; fr. very small, globular, black-red, somewhat astringent. Japan. B.M. 8034. R.H. 1876, p. 328. Gn. 50:454. F.M. 1871:536. G. 30:177. G.F. 1:198; 2:487 (old tree). Gng. 2:269. M.D.G. 1890:320, 321.—One of the handsomest of early-flowering trees, producing its chaste pink fls. in profusion. Hardy in Cent. N. Y. Seedlings sometimes have more erect and spreading

3242. *Prunus subhirtella* var. *pendula*, the rose-bud cherry ($\times \frac{1}{2}$). No. 64.

branches. Should be grown from seeds or worked on the upright forms of the species, according to Wilson, for it does not thrive on the European cherry stocks.

Var. *ascendens*, Wilson (*P. pendula* var. *ascendens*, Makino. *P. itosakura* var. *ascendens*, Koidz. *P. Herinoquiiana*, Koehne. *P. microlepis*, Koehne). Regarded by Wilson as the prototype of *P. subhirtella* and var. *pendula*. A tall strong tree with massive wide-spreading branches but the branchlets rather sparse and causing the head to have a thin appearance; lvs. somewhat larger than in *P. subhirtella* itself. Differs only in habit from var. *pendula*, and the two cannot be distinguished on the herbarium sheet. It is cult. in Japan, but is yet unknown as a horticultural plant in N. Amer. and Eu., although recently intro. Indigenous in Cent. China and probably also in Korea and Japan.

Var. *autumnalis*, Makino (*P. subhirtella* var. *Fukubana*, Makino. *P. autumnalis*, Koehne. *P. Makinoana*, Koehne. *P. microlepis* var. *Smithii*, Koehne. *P. Cerasus Chelii pendula*, Hort.). An abnormal form, semi-double, blooming in April and again in Oct.; bush-like in stature, with slender wide-spreading branches. G.C. III. 52:432; 58:244. Gn. 76, p. 628 (all as *P. Miqueliana*).—"The flowers in

autumn are smaller than those of spring, and in each case when the flowers are produced before the leaves or after the leaves have fallen the peduncle does not elongate and the plants present no striking differences. But on some individuals in the spring the leaves and flowers unfold at the same time and the peduncle is then much elongated. Such specimens look utterly dissimilar, yet whether the flowers open before or at the same time as the leaves is not fixed and may vary on the same individual from year to year."—Wilson.

DD. Lvs. prominently incised- or lobulate-double-serrate or -crenate: fls. usually appearing with the lvs.

65. *canescens*, Bois. Attractive shrub, 5-7 ft.: lvs. lanceolate, 2-2½ in. long, short-hairy on both surfaces, deeply bidentate, the teeth broader than long, cuspidate or mucronate, gland-tipped: fls. 2-5 together, rarely single, on the young shoots, white tinted rose; calyx-tube about ½ in. long; calyx-lobes or sepals shorter than the tube, serrulate or rarely entire, glabrous or nearly so on the inside; petals nearly ¼ in. long, oblong: fr. small, red. Cent. and W. China.

66. *lobulata*, Koehne. Tree, to 35 ft. or so, lately cult. abroad: lvs. oblong, obovate, or oblong-lanceolate, 1-3 in. long, somewhat acuminate, doubly serrate with the teeth strongly acuminate and either glandless or the gland a minute terminal point, glabrous or nearly so except perhaps sparsely hairy on nerves, with 1 or 2 glands at base of blade or at apex of petiole, apex of blade obtuse or obscurely emarginate: fls. white: fr. globose or nearly so, about 1 in. long, red. W. China.—Hardy in Mass.

67. *incisa*, Thunb. (*Cerasus incisa*, Loisel.). Allied to *P. lobulata*. Shrub, to 15 ft., or sometimes tree, to 30 ft.: lvs. ovate to obovate, acuminate, incisely doubly serrate, pubescent above and on the veins beneath or nearly glabrous, ¾-2½ in. long: fls. 1-3, nodding, with leafy bracts at base; calyx vinous-red; petals white or pink, rather fugaceous: fr. ovoid, purplish black, ¼ in. long. Japan. S.I.F. 1:28.—Cult. in Japan, making a very ornamental bush, but apparently unknown to planters in N. Amer.; it is now growing at the Arnold Arboretum.

68. *nipponica*, Matsum. (*P. iwagiensis* and *P. nikkoensis*, Koehne). Allied to *P. incisa*. Bushy tree, to 20 ft.: older branches chestnut-brown: lvs. ovate, long-acuminate, usually rounded at base, incisely doubly serrate, pubescent while young, finally nearly glabrous; petioles glabrous: fls. 1-3, slender-stalked, white or pale pink, 1 in. across: fr. globose, ½ in. across, black. Japan, at high altitudes, probably adaptable to cold locations in this country. Var. *kurilensis*, Wilson (*P. kurilensis*, Miyabe). Petioles pubescent: fls. somewhat larger; pedicels and calyx pubescent. Japan, Kurile Isls.

69. *apétala*, Franch. & Sav. (*Cerasus apétala*, Sieb. & Zucc. *P. crassipes*, Koidz. *P. Tschonéskii*, Koehne). Shrub or tree, with young branches glabrous: lvs. oblong or obovate-oblong, 1-2 in. long, caudate at apex, doubly serrate and as if somewhat lobed, the teeth narrow and tipped by gland, close-villous above and villous beneath, especially on the nerves; petiole short, densely villous, usually with 1 or 2 glands: fls. with deep purple calyx and sepals and very small fugaceous petals, 1-2 together, appearing with the lvs., the pedicels nearly 1 in. long and hairy; sepals or calyx-lobes ovate, about ½ in. long, very slightly hairy outside; stamens 26, shorter than the style. Japan.—The *P. apétala* mentioned in horticultural literature may be a form of *P. Maximowiczii*; but the present description is of the true species. Var. *pilösa*, Wilson, has much larger fls. and the branches are less hairy, and rather more floriferous than the type; superior horticulturally. *P. apétala* is little known in cult. in this country.

Subgenus IV. PADUS (including *Laurocerasus*). Racemed Cherries.

Fr. small and globular, rarely used for eating: fls. white, small, in distinct racemes, not preceding the lvs. or else arising from the axils of persistent lvs. of the year before.

A. *Padus proper*: lvs. deciduous: fls. on leafy shoots of the season (exception in No. 71).

B. *Calyx-lobes persistent at the base of the fr.: fls. appearing relatively late in the season: large trees.*

70. *serótina*, Ehrh. (*Padus serótina*, Agardh. *Cerasus serótina*, Loisel.). WILD BLACK CHERRY. Strong straight tree, reaching 100 ft., with very dark brown bitter aromatic bark: lvs. oblong, lance-oblong or oblong-ovate, tapering to a point, thickish and firm, shining above, with many small incurved callous teeth: fls. in long, loose racemes, appearing when the lvs. are nearly full grown: fr. size of a pea, purple-black, bitterish, ripening in late summer and Sept. Generally distributed from Nova Scotia to Dakota, south to Fla. and Texas. S.S. 4:159. F.E. 32:533.—A valuable timber tree, furnishing lumber for cabinet work and house finishings; also a fine lawn tree. It is much used in forestry plantings. Var. *péndula*, Dipp., has drooping branches. G.Z. 26:241. Var. *pyramidalis*, Zabel, is of narrow pyramidal growth. Var. *variegata*, Hort., has yellow-marked lvs. Var. *cartilaginea*, Dipp. (var. *carthagena*, Hort., by error. *P. cartilaginea*, Lehm.), is a handsome form with very long, shining lvs. Var. *asplenifolia*, Hort. (*Cerasus serótina* var. *asplenifolia*, Kirchn.), has narrow deeply toothed lvs. For a note on the nomenclature of *P. serótina*, see No. 72.

Var. *neomontana*, Sudw. (*Padus serótina* var. *neomontana*, Small), of the high mountains in the southern Alleghenies, has ample leathery coarsely serrate lvs. which are pale or whitish beneath, stout few-fl. diverging racemes, and sepals and filaments pubescent.

The *P. serótina* group is now held to include other species in the southern states and southward, but apparently they are not in cult. outside botanic gardens: *P. eximia*, Small (*Padus eximia*, Small), differs from *P. serótina* in having sepals or calyx-lobes deltoid and slightly broader than long rather than ovate, and lvs. delicately reticulated rather than plain. River-valleys, Texas. *P. Cuthbertii*, Small (*Padus Cuthbertii*, Small), differs from *P. serótina* in having young parts (young shoots, raceme-axis and pedicels) pubescent rather than glabrous: lvs. obovate and blunt, finely and rather sparingly pubescent beneath and becoming glabrate and glaucous with age: drupe red. Woods, Ga. *P. alabamensis*, Mohr (*Padus alabamensis*, Small), is distinguished from *P. Cuthbertii* in having lvs. ovate, oblong, or elliptic and acute or acuminate, and drupe purple. Mountains, Ga., Ala. *P. australis*, Beadle (*Padus australis*, Small), has young parts pubescent: lvs. not glaucous but densely and permanently clothed with colored tomentum. Ala. *P. Capóllin*, Koehne (*P. Capuli*, Cav. *Cerasus Capóllin*, DC.), from Mex., a very large tree with long and slender pedicels: lvs. lanceolate, long-acuminate: fr. large. *P. salicifolia*, HBK., in S. Amer. and probably not in Mex. as reported: evergreen, differing little from *P. Capuli* and presumably in need of closer definition: apparently not in cult., although the name occurs in horticultural literature.

BB. *Calyx-lobes or sepals not persistent on the fr.: fls. early: small trees.*

c. *Peduncle nude (not bearing lvs.).*

71. *Maackii*, Rupr. (*Laurocerasus Maackii*, Schneid.). Tree, to 50 ft., with shoots finely pubescent or becoming glabrate: lvs. oblong to oblong-ovate or elliptic, acuminate and pointed (2-4 in. long), finely and very sharply glandular-serrate, glabrous, gland-dotted

beneath, with 1 or 2 large glands near base of blade or at apex of the petiole (which is $\frac{3}{8}$ – $\frac{3}{4}$ in. long): fls. appearing on the ends of leafless shoots, white, long-stalked, less than $\frac{1}{2}$ in. across, the racemes 2–3 in. long and dense (1– $1\frac{1}{2}$ in. long). Amurland, Manchuria.

cc. *Peduncle bearing lvs.*

72. *virginiana*, Linn. (*Cerasus virginiana*, Loisel. *Prunus nana*, Du Roi. *Pädus nana*, Roem.). CHOKO CHERRY. Fig. 3243. Bush or sometimes a small tree 30 ft. tall, with rough speckled bark and a strong odor when bruised: lvs. thin, oval-oblong or obovate, abruptly pointed, very sharply serrate, with spreading or at least not incurved teeth: fls. in short, dense racemes in spring with the lvs.: fr. size of pea, in summer, red or amber-colored (the latter var. *leucocarpa*, Wats.), pucky; stone smooth. Generally distributed over N. N. Amer. to the Arctic Circle and occurring in the mountains of Mex. S.S. 4:158.—Now and then a large-fruited variety is found fit for eating. Sometimes planted for ornament. There is a weeping form, var.

3243. *Prunus virginiana*
($\times \frac{1}{2}$). No. 72.

péndula, Hort.; a dwarf form, var. *nana*, Hort.; a narrow-lvd. form, var. *salicifolia*, Hort. Other more or less distinct forms may be distinguished. Recently the name *P. nana*, Du Roi, has been used for this species, and *P. virginiana* has been made to supplant the name *P. serotina* (No. 70). Linnæus had two plants under *P. virginiana* in *Species Plantarum*. The synonyms cited by him clearly designate *P. serotina* (the black cherry), except one, which is an *Itea*; but his original description, to which he gave the name *P. virginiana* and which is based on material preserved in his herbarium, is of the chokecherry; and there seems to be no occasion to change the names of these well-known plants.

73. *demissa*, Walp. (*P. virginiana* var. *demissa*, Torr. *Cerasus demissa*, Nutt.). Lvs. more rounded than in *P. virginiana* or even subcordate, thicker, pubescent, serrate with straight teeth, the petioles glandular: fr. red, large, and edible. Wash., Ore., Calif., and probably eastward.—Considered by many to be worthy of improvement as a fruit-plant.

Var. *melanocarpa*, Nels. (*P. melanocarpa*, Shafer), has smooth lvs. and fr. nearly black when mature and more astringent: shrub or small tree: lvs. smooth or nearly so on both surfaces, the small serratures incurved or appressed, the petioles glandless: fls. white, in erect or ascending compact racemes. Rocky Mt. region and probably westward.

74. *Pädus*, Linn. (*P. racemosa*, Lam. *Pädus racemosa*, Schneid. *Pädus vulgaris*, Borkh. *Cerasus Pädus*, DC.). EUROPEAN BIRD CHERRY. Very like *P. virginiana*, but has larger fls. on longer pedicels, in longer and looser often drooping somewhat leafy racemes: lvs. elliptic to oblong-ovate to oval, broad at base, abruptly acuminate, very sharply serrate, glabrous, the petiole gland-bearing at apex: fls. appearing

a week later; petals $\frac{1}{4}$ – $\frac{1}{2}$ in. long and twice exceeding the stamens: stone rough. Eu. and Asia. Gn. 53, p. 92. G.M. 44:209. G. 20:601; 27:269.—Common in cult. in many forms: Var. *péndula*, Dipp., drooping; var. *variegata*, Hort., in several forms, as *auræa*, *aucubifolia*, *marmorata*, *Alberti*. Var. *leucocarpa*, Koch, has white or yellowish lvs. Var. *bracteosa*, Ser., has very large lvs. at the base of the racemes. Var. *commutata*, Dipp. (*P. Grayana*, Hort., not Maxim.), is noteworthy because it is one of the earliest of all trees to leaf out in spring. G.F. 1:295. Var. *plena*, Hort., is a double-fl. form. Variable in its foliage. Makes a shapely tree 10–20 ft. tall. Var. *cornuta*, Henry (*P. cornuta*, Steud.), of the Himalayas, has lvs. rounded at base and bluish green beneath with reddish hairs in the axils of the veins: pedicels and long racemes pubescent: fr. $\frac{1}{2}$ in. or less diam., the stone smooth. *P. Lauchiana*, Bolle, is a hybrid of this and *P. virginiana*.

75. *Grayana*, Maxim. (*P. Pädus* var. *japonica*, Miq.), is allied to *P. Pädus*. A small tree, 20–30 ft. high, with a slender trunk, ample membranaceous long-pointed setaceo-serrate lvs., biglandular at the base but without glands on the petioles, a peculiarity which best distinguishes this species, although the hair-like teeth of the lvs. are characteristic and apparently constant: style long rather than short as in *P. Pädus*. Japan.

76. *Ssiöri*, Schmidt (*Pädus Ssiöri*, Schneid.). Smaller-fl. than *P. Pädus*, with a smooth or only obscurely roughened stone: lvs. ovate, long-acuminate, strongly serrate with narrow teeth, not papillose beneath; petiole $\frac{1}{2}$ – $1\frac{1}{2}$ in. long, with usually 2 or more glands at apex: raceme 4–7 in. long, glabrous; petals white, about $\frac{1}{2}$ in. long, equaling the stamens. Manchuria, Saghalin, Japan.

AA. *Laurocerasus*: lvs. persistent (evergreen): fls. in spring in the axils of the lvs. of the previous year. (*Cherry-laurels*.)

B. *Racemes longer than the lvs.*

77. *lusitânica*, Linn. (*Pädus lusitânica*, Mill. *Laurocerasus lusitânica*, Roem.). PORTUGAL LAUREL. Tree, 20 ft. tall, but usually grown as a tub-plant and comparable with *Laurus nobilis*: lvs. thick and leathery, ovate-lanceolate to long-lanceolate, sharp-serrate: fls. white, in racemes that exceed the lvs., appearing in late spring or early summer: fr. round-oval, nearly black, small. Spain, Portugal, and Canary Isls.—It is a small tree in its native places, but becomes a bush farther north. It is sometimes planted in the open in our southern states, but in northern parts it is wintered inside. There is a form (var. *angustifolia*, Hort.) with narrow lvs., another (var. *myrtifolia*, Nichols.) with small lvs. and compact habit, and another (var. *aureo-variegata*, Hort.) with yellow-variegated lvs., and one (var. *variegata*, Nichols.) with lvs. variegated white. Var. *azórica*, Nichols., is a free grower with red sts.: lvs. more coriaceous and more coarsely serrate than the type: racemes short and densely fl.: shrubby. Azores. G. 30:123. Var. *Hixa*, DC. Lvs. narrower and more oblong than in the type, about 5 in. long: racemes 6–8 in. long, the fls. less crowded. Madeira and Canary Isls.

BB. *Racemes not longer than the lvs.*

c. *Calyx-lobes toothed or undulate.*

78. *Laurocerasus*, Linn. (*Cerasus Laurocerasus*, Loisel. *Pädus Laurocerasus*, Mill. *Laurocerasus officinalis*, Roem.). CHERRY-LAUREL. ENGLISH LAUREL. Bush or small tree (reaching 10 ft.) with handsome evergreen foliage: lvs. coriaceous and glossy, short-stalked, oval, lanceolate, oblong-elliptic or oblanceolate, narrowed into a short point, remotely serrulate, with 2–4 glands at the base of the blade: fls. small, white, in axillary or terminal short racemes in spring, the calyx-lobes 3-toothed: fr. ovoid-acute, small, blackish. S. E. Eu. to N. Persia. Gn. 50, p. 313.—One of

the most popular broad-lvd. evergreen plants in Eu., and somewhat planted in the southern states. It is also grown in tubs and used for house-decoration. Some of the forms will stand as far north as Washington, and var. *schipkaensis* is hardy in Cent. N. Y. When grown in the open, the cherry-laurel should be allowed to ripen its wood thoroughly before winter sets in. Protection from severe winds is always desirable. The plant may be prop. by means of long cuttings of ripe wood; also by layers. Named varieties are worked on common stocks. The cherry-laurel is very variable. Some of the many horticultural forms are as follows: Var. *angustifolia*, Nichols., lvs. very long and narrow, and plant hardy as far north as Washington; var. *Bérinii*, with very broad lvs.; var. *camelliaefolia*, Nichols., with recurved lvs.; var. *caucásica*, Hort., and var. *cólchica*, Hort., with slender twigs and dark foliage which is gray-green beneath, also hardy; var. *japónica*, Hort., a narrow-lvd. form, like var. *angustifolia*; var. *latifolia*, Hort., with broad lvs., hardy at Washington; var. *versailensis*, Hort., also with broad foliage; var. *microphylla*, Hort., with small, narrow lvs., only 4-5 in. long; var. *rotundifolia*, Nichols., with short-oblong blunt lvs. (Gn. 28, p. 405); var. *parvifolia*, Nichols., lvs. only $1\frac{1}{2}$ in. long and $\frac{1}{2}$ in. broad, coarsely serrate: shrub; var. *schipkaensis*, Spæth, with small nearly or completely entire lvs. dark green above and very light green beneath, shrubby, hardy in N. Y. (R.H. 1905. p. 409. G.W. 5, p. 177, var. *schipkaensis* *Zabeliana*); var. *variegata*, Nichols., lvs. marbled or blotched with dull white.

79. *caroliniana*, Ait. (*Prunus sempervirens*, Willd. *Cerasus caroliniana*, Michx. *Padus caroliniana*, Mill. *Laurocerasus caroliniana*, Roem. WILD ORANGE. Mock ORANGE of the S. Tree, 20-40 ft.: lvs. oblong-lanceolate-acuminate, usually entire but sometimes remotely spinose-serrulate, thick, dark green and shining above, the margins usually somewhat revolute: fls. cream-colored, in short rather close racemes, the calyx-lobes with undulate margins: fr. $\frac{1}{2}$ in. long, oblong-pointed, black, and shining, persisting for a year. S. C. to Fla. and Texas, in stream-valleys and near the coast. S.S. 4:160.—A handsome evergreen, prized for planting in the S. Blooms from Feb. to April.

80. *sphærocárpa*, Swartz (*Laurocerasus sphærocárpa*, Roem.). Small glabrous tree, 30-40 ft.: lvs. elliptic, 2-4 in. long, acuminate, shining, entire, the petioles slender but less than $\frac{1}{2}$ in. long: racemes rather dense, shorter than the lvs., the slender pedicels subtended by deciduous bracts; sepals or calyx-lobes lacinate and acute, deciduous, much smaller than the reflexed white petals which are yellow near base within: fr. nearly globular, pointed at apex, $\frac{1}{8}$ - $\frac{1}{2}$ in. diam., orange. S. Fla., W. Indies, Brazil.

cc. *Calyx-lobes entire.*

81. *ilicifolia*, Walp. (*Cerasus ilicifolia*, Nutt. *Laurocerasus ilicifolia*, Roem.). ISLAY. WILD CHERRY. EVERGREEN CHERRY. MOUNTAIN HOLLY. Evergreen bush or small tree, rarely becoming 30 ft. tall, with a dense crown: lvs. holly-like, ovate to ovate-lanceolate, obtuse, acute, or sometimes even acuminate, mostly broad and sometimes rounded at the base, the margins coarsely spiny-toothed, the blade thick and shining: fls. white, in slender racemes less than 2 in. long in spring, about $\frac{1}{2}$ in. across: fr. rather large (sometimes $\frac{3}{4}$ in. long), nearly globose, purple or nearly black; stone ovate. San Francisco to Low. Calif. Gn. 3, p. 131. S.S. 4:162. G.F. 5:475 (tree).—A most worthy garden-plant.

82. *Lyonii*, Sarg. (*Laurocerasus Lyonii*, Eastw. *Prunus occidentalis*, Lyon, not Swartz. *P. ilicifolia* var. *occidentalis*, Brandeg. *P. integrifolia*, Sarg., not Walp. *P. ilicifolia* var. *integrifolia*, Sudw.). ISLANDS

CHERRY. Lvs. longer and more acuminate, usually entire: fr. larger. Islands off the coast of S. Calif. (Santa Cruz and Santa Catalina). S.S. 4:163.—Considered to be more desirable as a garden-plant than No. 81. It grows rapidly under cult., making a compact very dark green crown. Useful also in pots and tubs. *P. occidentalis*, Swartz, a different plant, grows from Cuba to Trinidad. It is not in the trade. Grisebach describes it as a high tree: lvs. oblong or ovate-oblong, rounded at the base, bluish, with 2 glandular spots at the base beneath: racemes lateral, puberulous or glabrous: fr. ovoid, slightly apiculate, nearly 1 in. long, purple. The fr. is said to be "of very fine flavor."

P. bicolor, Koehne. Allied to *P. Padus*. Tree, to 40 ft.: branchlets finely velutinous: lvs. obovate-oblong, acuminate, subcordate or rounded at base, serrulate, glabrous and whitish beneath, 2-4 in. long: fruiting raceme to 5 in. long: fr. globose, $\frac{1}{2}$ in. across. W. China.—*P. canadensis*, Koehne. Allied to *P. Maximowiczii*. Tree, to 30 ft.: lvs. obovate, acuminate, usually rounded at base, doubly serrate, finally glabrous, $1\frac{1}{2}$ - $3\frac{1}{2}$ in. long: fls. white, about $\frac{1}{2}$ in. across, in 5-8-fld. racemes: fr. ovoid, red. W. China.—*P. concinna*, Koehne (*P. Zappeyana*, Koehne). Allied to *P. lobulata* (and has been cult. as *P. subhirtella*). Shrub, to 15 ft.: lvs. rhombic-oblong to obovate-oblong, acuminate, rounded at the base, doubly incised-serrate, nearly glabrous, 1-3 in. long: fls. white, 1-2, precocious, about $\frac{3}{4}$ in. across; pedicels and calyx glabrous: fr. dark red or black. Cent. China.—*P. consociiflora*, Schneid.—*P. salicina*.—*P. cyclodroma*, Koehne (subgen. *Cerasus*). Tree, to 25 ft.: lvs. obovate-oblong, acuminate, rounded at base, sharply simply or doubly serrate, at first sparingly pubescent on the veins, 2-4 in. long: fls. umbellate, 3-4, pink, $1\frac{1}{2}$ in. across; sepals reflexed: fr. subglobose, red, $\frac{1}{2}$ in. across. Cent. China.—*P. dehtscens*, Koehne (subgen. *Amygdalus*). Spiny shrub, to 12 ft.: lvs. usually fascicled, oblong to oblanceolate, acute or obtuse, cuneate at the base, crenulate, glabrous, $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. subsessile; sepals roundish: fr. roundish, slightly compressed, about $\frac{1}{2}$ in. across, greenish, densely tomentose, finally dehiscent; stone slightly compressed, keeled, slightly rugose. W. China.—*P. Dielsiana*, Schneid. (subgen. *Cerasus*). Shrub or tree, to 30 ft.: lvs. oblong, abruptly acuminate, cuneate or rounded at the base, simply or doubly serrate, pubescent beneath, 3-6 in. long: fls. umbellate, 3-5, with persistent involucre, white or pink, $1\frac{1}{4}$ in. across; sepals reflexed, oblong to lanceolate: fr. globose, red, $\frac{1}{2}$ in. across. Cent. China.—*P. discadenia*, Koehne. Allied to *P. Maximowiczii*. Shrub or tree, to 35 ft.: lvs. ovate or obovate, acuminate, usually rounded or cordate at base, unequally serrate, glabrous, 2-4 in. long: fls. white, $\frac{3}{4}$ in. across, in 3-9-fld. racemes: fr. subglobose, $\frac{3}{4}$ in. across. Cent. China.—*P. glyptocarya*, Koehne. Allied to *P. lobulata*. Tree, to 30 ft.: branchlets pubescent: lvs. oblong to obovate-oblong, acuminate, usually rounded at base, deeply doubly serrate, pubescent beneath, 2-4 $\frac{1}{2}$ in. long: fls. umbellate: fr. globose, $\frac{1}{2}$ in. across, dark red; stone reticulate and ribbed. W. China.—*P. Jacquemontii*, Hook. f. Allied to *P. prostrata*. Low shrub, glabrous: lvs. elliptic-oblong, acute or short-acuminate, cuneate at base, serrate, light green beneath, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long: fls. 1-3, short-stalked, pink, $\frac{1}{2}$ in. across; calyx tubular: fr. ovoid, $\frac{1}{2}$ in. long, dark purple. W. Himalayas. B.M. 6976.—*P. macrophylla*, Sieb. & Zucc. Allied to *P. Laurocerasus*. Evergreen tree, to 30 ft.: lvs. oblong, acuminate, broadly cuneate at base, serrulate, glabrous, 4-7 in. long: fls. white, in dense racemes 1-1 $\frac{1}{2}$ in. long: fr. ovoid, $\frac{3}{4}$ in. long. S. Japan. S.I.F. 1:29.—*P. mira*, Koehne. Allied to *P. Persica*. Tree, to 30 ft.: lvs. lanceolate, long-acuminate, rounded at base, crenulate-serrulate, villous beneath along the midrib, otherwise glabrous, 2-4 in. long: fr. short-stalked, subglobose, $1\frac{1}{2}$ in. across, tomentose, edible; stone ovate, compressed, keeled, smooth. W. China. Differs from all peaches in its smooth stone. Hardy at Arnold Arboretum.—*P. persulata*, Koehne (subgen. *Padus*). Tree, to 40 ft.: lvs. elliptic to oblanceolate, acuminate, rounded or broadly cuneate at base, serrulate, sparingly pubescent beneath, $2\frac{1}{2}$ - $4\frac{1}{2}$ in. long: racemes 2-3 in. long, velutinous, with a persistent involucre at base, leafless: fr. globose, $\frac{1}{2}$ in. across; calyx persistent. W. China.—*P. pleiocerasus*, Koehne. Allied to *P. Maximowiczii*. Tree, to 25 ft.: lvs. obovate-oblong, caudate-acuminate, rounded or cuneate at base, unequally serrate, glabrous or nearly so beneath, $1\frac{3}{4}$ - $3\frac{1}{2}$ in. long: fls. white, in 4-7-fld. racemes: fr. globose, dark red or black. W. China.—*P. pleuriptera*, Koehne. Allied to *P. lobulata*. Tree, to 30 ft.: branchlets hairy: lvs. obovate to rhombic-oblong, acuminate, usually cuneate at base, incised doubly serrate, pubescent beneath on the veins, $\frac{3}{4}$ - $2\frac{1}{2}$ in. long: fr. usually solitary, subglobose, $\frac{1}{2}$ in. long, black; stone sulcate and foveolate. W. China.—*P. polytricha*, Koehne. Allied to *P. Maximowiczii*. Tree, to 30 ft.: branchlets villous: lvs. obovate to obovate-oblong, caudate, usually rounded at base, doubly serrate, pubescent on both sides, $1\frac{1}{2}$ -3 in. long: frs. 1-2 on a bracted peduncle $\frac{1}{2}$ - $\frac{1}{2}$ in. long, ovoid, red, $\frac{1}{2}$ in. long; pedicels villous, about 1 in. long. Cent. China.—*P. pubigera*, Koehne (*P. pubigera* var. *Potaniini*, Koehne). Allied to *P. Padus*. Tree, to 60 ft.: branchlets minutely velutinous: lvs. obovate-oblong, short-acuminate, subcordate or cordate at the base, minutely serrulate, glabrous and whitish beneath, $1\frac{1}{2}$ - $4\frac{1}{4}$ in. long; petioles puberulous: racemes 3-6 in. long: fr. about $\frac{1}{2}$ in. across. W. China. Var. *Pratii*, Koehne. Lvs. cuneate or rounded at base; petioles glabrous. Var. *obovata*, Koehne. Lvs. obovate, rounded at base; petioles glabrous.—*P. rufomaculata*, Koehne (subgen. *Padus*). Tree, to 80 ft.: lvs. of flowering branchlets lanceolate to oblong-lanceolate, about 2 in. long, of sterile branches usually obovate, 3-4 in.

long, sharply serrulate, rufous-tomentose beneath: fruiting raceme 5 in. long, glabrous: fr. subglobose, $\frac{1}{2}$ in. across. W. China.—*P. sericea*, Koehne (*P. napaulensis* var. *sericea*, Batal). Tree, to 80 ft.: lvs. elliptic to oblong, rounded or cuneate at base, remotely serrate, white-tomentose at first, later grayish tomentose, 3–5 in. long: racemes 4–5 in. long, densely short-pilose: fr. subglobose, $\frac{1}{2}$ in. long, black. W. China.—*P. stellipila*, Koehne (subgen. *Padus*). Tree, to 20 ft.: lvs. elliptic to narrow-oblong, long-acuminate, broadly cuneate or nearly rounded at base, sharply serrate, sparingly pubescent beneath, 2–4 in. long: racemes upright, $1\frac{1}{2}$ –2 in. long, without lvs. at the base: fr. globose, $\frac{1}{2}$ in. across. Cent. China.—*P. tangutica*, Koehne (*Amygdalus communis* var. *tangutica*, Batal). Spiny shrub: lvs. fascicled, lanceolate, obtuse or acutish, crenulate-serrulate, 1–2 in. long: fr. sessile, about 1 in. across: fr. subglobose, $\frac{1}{2}$ in. across, somewhat compressed, rather dry; stone irregularly furrowed. N. W. China.—*P. tatsienensis*, Batal. Allied to *P. Maximowiczii*. Tree: lvs. ovate to obovate, acuminate, serrulate, $1\frac{1}{2}$ –2 $\frac{1}{2}$ in. long: fls. white, $\frac{3}{4}$ in. across in 3–7-fld. racemes with large leafy bracts. W. China. Var. *stenadenia*, Koehne. Tree, to 30 ft., quite glabrous: lvs. obovate-oblong, caudate, cuneate or rounded at base: fr. globose, dark red, $\frac{1}{2}$ in. across. W. China.—*P. venosa*, Koehne (subgen. *Padus*). Tree, to 35 ft.: lvs. oblong-obovate to obovate-oblancheolate, acuminate, cuneate or nearly rounded at base, sharply serrate, reticulate beneath, glabrous except the bearded axils, $2\frac{1}{2}$ –4 $\frac{1}{2}$ in. long: racemes without lvs. at base, $1\frac{1}{2}$ –4 in. long: fr. globose, about $\frac{1}{2}$ in. across. Cent. China.—*P. Wilsonii*, Koehne (*Padus Wilsonii*, Schneid.). Tree, to 30 ft.: lvs. elliptic-oblong to obovate-oblong, acuminate, usually cuneate at base, remotely serrate, whitish pubescent beneath, $3\frac{1}{2}$ –5 in. long: racemes pubescent, 5–6 in. long: fr. ovoid, $\frac{1}{2}$ in. long, black. Cent. China. Var. *leibothrys*, Koehne. Lvs. closely serrulate, grayish beneath; racemes glabrous.—*P. Zappayana*, Koehne=*P. concinna*. L. H. B.

PSÁMMA: *Ammophila*.

PSEUDERÁNTHEMUM (Greek, false *Eranthemum*, the genus resembling *Eranthemum* from which it was separated). *Acanthaceae*. Smooth bushes or shrubs with often coarse-toothed leaves and mostly brilliant colored flowers; glasshouse subjects.

Inflorescence racemose, 1–3-branched or simple in the axils of the bracts; fls. long-tubed, corolla with the limb spreading; lobes almost equal or the 2 rear ones smaller; stamens short, fastened in the tube, 2 staminoids present, true stamens 4 or less.—Sixty to 70 species, occurring in the tropics of both hemispheres. *Pseuderanthemum*, as characterized by Lindau in Engler and Prantl, *Pflanzenfamilien* IV 36:330, includes *Eranthemum* of Auth. not of Linn., and *Eranthemum* of Linn. is used for *Dædalacanthus* as treated in this work (see Vol. II, p. 950); and this constitutes the accepted treatment. There are a large number of horticultural species, a partial list of which occurs under *Eranthemum* (see Vol. II, p. 1126). Many of the species are cult. for their variegated foliage while others are grown for their fls. Warmhouse plants, prop. by cuttings any time from March to June.

Andersonii, Lindau (*Eranthemum Andersonii*, Mast.). Lvs. large, lanceolate, acute at both ends, glabrous: spike 10 in. long, lower clusters distant, many-fld., upper few-fld., continuous; corolla white, midlobe of lower lip spotted with purple; ovary ovoid-oblong. Asia(?). B.M. 5771. Gn. 45:11. G.Z. 25:49. See p. 1126.

cinnabarinum, Radlkf. (*Eranthemum cinnabarinum*, Wall.). Lvs. large, elliptic, acuminate at both ends: panicles compound, stout; corolla crimson, tube linear to the apex, sometimes a yellowish spot on the middle lobe of the lower lip. Burma. B.M. 5921 (as *E. cinnabarinum* var. *ocellatum*, the variety differing in the maculate lvs.).

laxiflorum, Hubb. (*Eranthemum laxiflorum*, Gray). Two to 4 ft. high, glabrous: lvs. oval or lanceolate-oblong: cymes few or many-fld., axillary, usually with a pair of lf.-like bracts; corolla salver-shaped, reddish purple; ovary oblong, conical, glabrous. Fiji Isl. B.M. 6336. See p. 1126.

lilacinum, Stapf. About 3 ft. high: lvs. lanceolate, long-acuminate: infl. paniculate; corolla-tube narrow, straight, almost white, limb 2-lipped, lilac-blue with a white or yellowish blotch, midlobe of lower lip red-specked. Malaya. B.M. 8446.

malaccense, Lindau (*Eranthemum malaccense*, C. B. Clarke). Three to 5 ft. high: lvs. lanceolate to elliptic-

lanceolate, base cuneate: infl. $\frac{1}{2}$ –2 in. long, numerous-fld., many opening together in whorls, finally raceme-like; corolla salver-shaped, tube nearly straight, pale violet, limb 2-lipped, pale violet or violet-white with red specks on the midlobe of the lower lip. Malaya. B.M. 8368.

pulchellum, Merr. (*P. bicolor*, Radlkf. *Eranthemum pulchellum*, Hort., not Auth. *E. bicolor*, Schrank). About 3 ft. high: lvs. thin, elliptic-ovate to oblong-lanceolate, acute or acuminate: corolla white, middle lobe of lower lip with a large purple spot. Malaya and Polynesia.

reticulatum, Radlkf. (*Eranthemum reticulatum*, Hort. *E. Schomburgkii*, Hort.). Lvs. opposite, lower ovate-lanceolate, dark green above with arching golden nerves, upper narrower, reticulated golden yellow and green: corolla white, speckled with blood-red around the mouth of the tube. Austral. or Polynesia (?). B.M. 7480. I.H. 26:349. See p. 1126.

seticalyx, Stapf (*Eranthemum seticalyx*, C. B. Clarke). Erect, somewhat hirsute: branches terete: lvs. ovate, acuminate: infl. spicate, terminal also in upper lf.-axils; calyx with white-spreading bristles; corolla salver-shaped, tube long, pale red, limb cinnabar-red above, paler beneath, 1 in. across. Trop. Afr. B.M. 8244.

tuberculatum, Radlkf. (*Eranthemum tuberculatum*, Hook. f.). Small shrub, much branched: lvs. small, elliptical or subovate: fls. very numerous, axillary, solitary, pure white, almost sessile. Polynesia. B.M. 5405. See p. 1126. F. TRACY HUBBARD.

PSEUDOLÁRIX (Greek, *pseudos*, false, and *Larix*; being similar to, but not a true larch). Syn., *Laricopsis*. *Pinaceae*. GOLDEN LARCH. Ornamental tree, grown for its handsome feathery foliage.

3244. *Pseudolarix Kaempferi*. ($\times \frac{1}{2}$)

Deciduous, with horizontally spreading whorled branches: lvs. linear, in dense clusters on short spurs, those of the young shoots spirally arranged: staminate fls. catkin-like, slender-stalked and clustered at the end of short spurs; cone short-stalked, pendent, with ovate-lanceolate deciduous scales and with bracts about half as long as the scales; each scale with 2 seeds with the wings nearly as long as the scale.—The only species is known wild only from a restricted region in E. China, where it grows in the mountains at an altitude of about 3,000–4,000 ft. It is closely allied to *Larix*, but differs by the stalked, pendulous, clustered, staminate fls. and by the deciduous cone-scales, which separate from the axis at maturity, as in the fir.

The golden larch is a beautiful tree with its long, spreading branches pendulous at the extremities and clothed with light green feathery foliage turning to a clear yellow in fall. The tree seems to remain free from insect pests and fungous diseases and is hardy in Massachusetts, and probably farther north. It requires a sunny open position and a well-drained moderately moist soil; it does not thrive nor look well if crowded by other trees. The golden larch should be raised only from seeds. If grafted on its own roots or on the common larch, as is sometimes done, it rarely grows into a symmetrical tree.

Kaëmpferi, Gord. (*P. Fortunei*, Mayr. *Larix Kaëmpferi*, Fort. *Laricopsis Kaëmpferi*, Kent). Fig. 3244. Tree, becoming 130 ft. high: lvs. linear, acuminate, soft, light green, bluish green beneath, $1\frac{1}{2}$ –3 in. long and $1\frac{1}{2}$ lines broad: staminate fls. yellow, about $\frac{1}{4}$ in. long, slender-stalked; pistillate fls. about $\frac{3}{4}$ in. long: cone ovate, reddish brown, $2\frac{1}{2}$ –3 in. long, $1\frac{3}{4}$ –2 in. broad; scales triangular, ovate-lanceolate, cordate at the base, emarginate at the apex, woody; bracts ovate-lanceolate, much smaller than the scales; seeds about $\frac{1}{2}$ in. long. F.S. 17:1777, 1778. R.H. 1868:331; 1871, pp. 608, 609. G.C. II. 19:88. Gn. 8, p. 325; 29, p. 397. G.W. 3, p. 123; 14, p. 603. F.E. 19:236 (pl. 94). B.M. 8176. Var. *nana*, Beissn. Dwarf form, cult. in China and Japan; without much decorative value.

ALFRED REHDER.

PSEUDOPANAX (*false Panax*). *Araliaceæ*. A small and horticulturally unimportant group of greenhouse aralias grown for their foliage, flowers having never developed in cultivation, so far as known, in America.

Glabrous shrubs or rarely trees in cult.: lvs. digitately compound, and sometimes simple, the juvenile lvs. quite unlike mature specimens: fls. dioecious, in racemose or paniculate umbels; calyx-limb entire or toothed; corolla of 5 distinct, valvate petals; stamens 5; ovary 5-celled: fr. fleshy.—Only 6 species are known, as here understood all from the islands of New Zealand. Cult. as in *Dizygotheca*.

crassifolium, Koch (*Aralia crassifolia*, Soland, *Dizygotheca crassifolia*, Taylor). In cult. a shrub, often a tree 20–40 ft. high in nature: lvs. very variable, those of seedlings rhomboid to ovate-lanceolate; of young, unbranched plants very narrow-linear, sometimes 1-foliolate and rigid, erect or sometimes 3–4-foliolate: umbels terminal, compound: fr. globose, $\frac{1}{2}$ in. diam.

P. Kerchoveanum, Hort. (*Aralia Kerchoveana*)=*Dizygotheca*. See *Polyscias* for related plants.

N. TAYLOR.

PSEUDOPHŒNIX (Greek, *false Phoenix*). *Palmaceæ*, tribe *Areceæ*. Until very recently only one recognized species, a pinnate-leaved palm discovered in 1886

on Elliott's Key, Florida, and distinguished from all other North American palms by its scarlet-orange fruit, which is about the size of a cherry.

Unarmed palms, with spindle-shaped trunk: spadix shorter than the lvs., pendulous, branched,

almost zigzag: female fl. with calyx small, spreading, somewhat denticulate; petals 3, ovate, obtuse, green, bent back; staminodia 6, distinctly dark purple at the top: fr. a drupe, stipitate, containing 1–3 globular carpels. Allied to royal palm (*Oreodoxa*), but differing in color of fr. and in spreading rather than ascending or erect spadix-branches.

Sargentii, Wendl. Fig. 3245. Trunk slender, 20–25

ft. high, 10–12 in. thick: lvs. abruptly pinnate, 4–5 ft. long; pinnae lanceolate, acuminate, 12–16 in. long, bright green above, glaucous beneath, folded backward at the very base: spadix appears from among the lvs.; main and secondary branches light yellow-green and flattened: fr. usually 3-lobed, $\frac{1}{2}$ – $\frac{3}{4}$ in. thick, bright orange-scarlet. Fla. Keys and the larger W. Indies. G.F. 1:353, 355 (adapted in Fig. 3245).—The tree is somewhat planted in S. Fla. (see p. 2445), but the plantings in S. Calif., appear to have been lost.

P. vinifera, Becc. (*Euterpe vinifera*, Mart.), of Haiti, is apparently not in cult. Evidently this palm was once common in that island, but probably it has been destroyed by the natives who fell the trees to extract the saccharine juice of the inflated part of the trunk and from which a fermented drink is made. The trunk is apparently more ventricose than that of *P. Sargentii*, the spadix is more diffuse and the branchlets more elongate, and the fr. pedicellate but 1-seeded.

N. TAYLOR.†

PSEUDOTSUGA (Greek, *false Tsuga*). Syn., *Abietia*. *Pinaceæ*. Ornamental woody plants grown for their regular pyramidal habit and evergreen foliage; also important timber trees.

Tall evergreen trees with whorled branches: lvs. more or less 2-ranked, linear, flattened, green and grooved above, with a stomatiferous white band on each side of the prominent midrib beneath, with only 1 vascular bundle in the center: staminate fls. axillary, cylindric: cones pendent, ovate-oblong, maturing the same season; scales rounded, rigid, persistent; bracts longer than the scales, 2-lobed at the apex with the midrib produced into a rigid awn; each scale with 2 nearly triangular seeds with a wing shorter than the scale.—Four species, 2 in W. N. Amer., 1 in Japan, and 1 in W. China. Very similar in habit and foliage to *Abies*, from which *Pseudotsuga* without cones can be easily distinguished by the more slender and flexible lvs. and the elongated, ovate or ovate-oblong, acute, not resinous winter buds; from *Tsuga* it may be distinguished without cones by the smooth branches, not roughened by the persistent lf.-bases, and the longer lvs. The light red or yellow wood is hard and durable and much used for construction, for railway ties and for masts. The bark is sometimes used for tanning leather.

The Douglas spruce, which is the only species well known in cultivation, is a tall tree of symmetrical habit with regularly whorled branches clothed with more or less two-ranked linear leaves, with orange staminate and purplish pistillate catkins and with pendulous medium-sized cones of somewhat bristly appearance on account of the protruding bracts, falling off as a whole. It is one of the tallest and most important forest and timber trees of western North America, and in its forms of the higher altitudes it is hardy as far north as Canada. When it finds a congenial home it is among the most desirable conifers for park planting and it grows rapidly, but where rapid growth is not desired, the var. *glauca* may be planted, which is of much slower growth and more compact habit. It thrives best in a porous sandy loam, and its cultivation does not differ from that of *Picea*, which see. Varieties may be grafted on the type.

The Douglas spruce is a tree for the million. It would be difficult to overrate its beauty. As a forest tree it perhaps produces a greater crop of lumber to the acre than any other species. It probably grows faster than any other conifer. Indeed, the complaint is sometimes made that it grows too fast to make a compact lawn tree. It is desirable to have groups of Douglas spruce, because the foliage is so soft that single specimens are sometimes injured by high winds. Specimens planted on the prairies without protection from hot winds may sometimes have their buds injured by late spring frosts. It is, of course, a mistake to use this kind of spruce for a windbreak. The Douglas spruce is generally propagated by seeds. Seeds of conifers gathered on the Pacific slope are tender, while those gathered in Colorado produce hardy trees which endure

3245. Fruit of *Pseudophœnix Sargentii*.
($\times \frac{1}{2}$)

both drought and cold. Unlike the firs, the Douglas spruce has fine fibrous roots like the Norway spruce and transplants as readily. The writer has transplanted many stocky young trees growing in the open to the nursery and has saved 90 per cent of them. They seemed to thrive as well as nursery-grown Norway spruces of the same size. The yield of seed from a wagon-load of cones is light, and it is somewhat difficult to grow seedlings. In some circumstances it will be cheaper in the end to procure young trees. The Douglas spruce is remarkable for its wide variation in form and color. The needles may be short or long, light green, dark green, or have a bluish or silvery cast. The deep blue and silvery foliage is characteristic of the deep gorges of high altitudes. (C. S. Harrison.)

taxifolia, Brit. (*P. Douglasii*, Carr. *P. mucronata*, Sudw. *P. Lindleyana*, Carr. *Abies Douglasii*, Lindl. *Abietia Douglasii*, Kent). DOUGLAS SPRUCE. RED FIR. Fig. 3246. Pyramidal tree, attaining 200 ft. and sometimes more, with a trunk becoming 12 ft. diam. clothed with ridged dark red-brown bark: branches horizontal, with

3246. *Pseudotsuga taxifolia*. ($\times \frac{1}{2}$)

pendulous branchlets: lvs. linear, straight or curved, obtuse, slender and flexible, dark green or bluish green, $\frac{3}{4}$ – $1\frac{1}{4}$ in. long: staminate catkins orange, pistillate reddish: cones pendulous, oval-ovate, with broad rounded scales and much exserted bracts 2– $4\frac{1}{2}$ in. long; seed $\frac{1}{4}$ in. long, with broad wing, light reddish brown. Brit. Col. to Mex., west to Mont. and Colo. S.S. 12:607. G.F. 10:295. Gn. 31, p. 288. R.H. 1868: 151. M.D. 1901:1; 1909, p. 69. G.W. 10, p. 565; 13, p. 411. There are many forms in cult. Var. *viridis*, Schneid. (*P. Douglasii viridis*, Schwerin), is the typical green-lvd. rapid-growing form. Var. *cæsia*, Schneid. (*P. Douglasii cæsia*, Schwerin), agrees with the type except that the lvs. are bluish green; it seems to be somewhat hardier. Var. *glauca*, Schneid. (*P. Douglasii glauca*, Mayr. *P. glauca*, Mayr). Of more compact habit: branches more ascending: lvs. shorter, bluish green: cones smaller, with often reflexed bracts. Colo. G.C. III. 36:53. Hardier than the type, but of slower growth. Var. *argentea*, Schneid. (*P. Douglasii argentea*, Koster). Similar to the preceding, with almost silvery white foliage. *P. Douglasii glauca elegans*,

Mottet, is scarcely different. R.H. 1914, p. 344. Var. *glaucescens*, Schneid. (*P. glaucescens*, Baily). With bluish white foliage and pendent branchlets. N. Mex. R.H. 1895:88; 1903, p. 208. Var. *péndula*, Schneid. (*P. Douglasii péndula*, Engelm.). With pendulous branches and dark green foliage. Var. *glauca péndula*, Schneid. (*P. Douglasii glauca péndula*, Beissn.). With pendulous branches and bluish green or bluish white foliage. Var. *fastigiata*, Schneid. (*P. Douglasii fastigiata*, Carr.). A narrow conical pyramid with ascending branches and shorter lvs. Var. *compacta*, Schneid. A compact conical form with short and dense foliage. Var. *globosa*, Rehd. (*P. Douglasii globosa*, Beissn.). A dwarf globose form. M.D. 1905, p. 75. Var. *Frétsii* (*P. Douglasii Frétsii*, Beissn.). Compact: lvs. very much shortened. Var. *Moerheimii* (*P. Douglasii Moerheimii*, Ruijs). With compact habit and finer deeper blue foliage than in the type. There are also some forms with variegated lvs.

P. japonica, Beissn. (*Tsuga japonica*, Shirasawa). Tree, to 60 ft.: branches glabrous: lvs. shorter, emarginate, often curved: cones smaller, $1\frac{3}{4}$ –2 in. long, with reflexed bracts. Japan. G.C. III. 45:307. S.I.F. 1:7. Has proved tenderer than *P. taxifolia* at the Arnold Arboretum.—*P. macrocarpa*, Mayr (*P. Douglasii* var. *macrocarpa*, Engelm. *Abies macrocarpa*, Vasey). Tree, to 60 or 80 ft., with remote and usually pendulous branches: lvs. acute, bluish gray: cones 4– $6\frac{1}{2}$ in. long, with shorter bracts; seeds $\frac{1}{2}$ in. long. S. Calif. S.S. 12:608. G.F. 10:25. Seems not yet intro.; not hardy N.—*P. sinensis*, Dode. Tall tree: branches pubescent: lvs. emarginate: cones about 2 in. long. S. W. China. Probably tender.—*P. Davidiana*, Bertrand, *P. Fortunei*, Carr., and *P. jesoensis*, Bertrand—Keteleeria.

ALFRED REHDER.

PSIDIUM (Greek, *psidion*, the pomegranate). *Myrtaceæ*. A large group of tropical and subtropical trees and shrubs, all native to America, many of which produce edible fruits. The common guava of the tropics, *P. Guajava*, is the best known. It has become naturalized in many parts of Asia and Africa. See *Guava*.

Leaves opposite, petiolate, glabrous, pubescent or tomentose, pinnately veined: fls. usually rather large, whitish, on axillary or lateral 1–3- (rarely many-) fld. peduncles; calyx-tube urceolate or pyriform, lobes 4–5, persistent; calyx sometimes closed before anthesis and splitting irregularly into 2–5 lobes; petals 4 or 5, spreading; stamens numerous, disposed in many series and inserted upon the disk, filaments filiform, anthers oblong or linear, basifixed, longitudinally dehiscent; ovary with 2–7, commonly 4, locules, the style slender, stigma peltate or subcapitate: fr. a berry, ovoid, globose or pyriform, commonly 1–3 in. long, yellow to red in color, sometimes green, crowned with the calyx-limb; seeds few to numerous, small, hard.—About 150 species. The genus is somewhat confused and in need of further study. A large number of species doubtless exist in S. and Cent. Amer., which have not as yet been described. The genus is allied to the myrtles (*Myrtus*), the pomegranate (*Punica*), and the various *Eugénias*, of which a number are cult. in the tropics for their frs. The following treatment includes the principal ones known to horticulture.

A. Branchlets 4-angled.

Guajava, Linn. **GUAVA**. Fig. 3247. An arborescent shrub or small tree, up to 25 or 30 ft. high, the trunk rather slender, usually dividing close to the ground, the bark scaly, smooth, greenish brown: lvs. oblong-elliptic, elliptic, or oval, 3–6 in. long, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. broad, chartaceous, rounded to acute at apex, rounded at base, light green, finely pubescent below, the venation conspicuously impressed above and raised below; petiole $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long: fls. produced on branchlets of recent growth, solitary or on 2- or 3-fld. peduncles, axillary; pedicel $\frac{3}{4}$ in. long, bearing at its upper end 2 small, slender bracts; calyx-tube oblong-ovate, slightly constricted above the ovary; calyx closed before anthesis, splitting into 2–4 irregular segms., whitish and sparsely hairy within; petals broadly oval, about $\frac{3}{4}$ in. long, thin and delicate, white; stamens erect or spreading,

in a broad cluster, the filaments about $\frac{1}{2}$ in. long, anthers pale straw-colored; style about $\frac{3}{8}$ in. high, stigma subcapitate, greenish; fr. globose, ovoid or pyriform, 1-4 in. long, commonly yellowish in color with flesh varying from whitish or yellowish to deep pink; flavor sweet or somewhat acid, with a pronounced musky aroma; seeds usually numerous, reniform or flattened. Flowers most abundantly in spring and produces the main crop of frs. in Aug. and Sept. Mex. and Cent. Amer., perhaps as far south as Peru.—This species is variable, and occurs in a wide range of horticultural forms. The two species *pyriferum* and *pomiferum* of Linnaeus are considered to be nothing more than round and pear-shaped varieties, and are no longer accorded botanical standing. A large guava, which appears to be a horticultural form of this species, was formerly offered by Reasoner Bros. of Fla. under the name of *P. guineense*, but is now being called Guinea guava and referred to *P. Guajava*. It is a large sweet fr. of excellent flavor, with unusually few seeds and thick flesh. In Calif. this variety has been called *P. guianense*. A round red-fleshed guava intro. to Calif. by Franceschi under the name of *P. aromaticum* also appears to be a horticultural variety of *P. Guajava*. The variety Perico has been disseminated in Fla.; other forms are commonly listed by nurserymen under such names as "sweet," "sour," "red-fleshed," and the like. In Calif., where this species is less commonly grown than in Fla., an oval yellow-fleshed form is called lemon guava, a pyriform white-fleshed one is known as pear guava, and a yellow one with pink flesh is called Hawaiian guava.

The name guayaba, by which the fruit is known in Spanish (the plant guayabo) is generally considered to have come from the island of Santo Domingo. Both Barbosa Rodrigues and Tavares, however, assert that it originated with the Tupi Indians in Brazil. In French the fruit is called goyave, the plant goyavier; in Portuguese goiaba, the plant goiabeira; and in German gujava, the plant gujavabaum. The aboriginal name in Mexico is xalxocotl, meaning sand-apple or sand-plum. Xocotl was the name applied by the Aztecs to all sour fruits, in contradistinction to zapotl which indicated all sweet ones.

Friedrichsthaliänium, Niedenzu (*Calyptrapsidium Friedrichsthaliänium*, Berg). COSTA RICAN GUAVA. CAS. Tree, 25-35 ft. high, with rather slender branches and smooth, dark brown bark, the young branchlets dark-colored, slightly pubescent: lvs. oval or oblong-oval, $1\frac{1}{2}$ -3 in. long, acuminate, the base acute, deep green, thickly chartaceous, smooth, almost glossy above, puberulent below, sparsely pellucid-punctate, midrib prominent below: peduncles axillary on the young branchlets, 1-fld.; petals 5, suborbicular; stigma peltate; ovary 5-locular: frs. globose, small, sour. Costa Rica, Guatemala, and probably other parts of Cent. Amer.—Of comparatively recent intro. into the U. S. It grows well in S. Fla., but seems too tender for most parts of S. Calif. It may succeed in protected locations. The frs. are considered especially valuable for jelly-making, because of their acidity. A plant which has been disseminated in this country under the name of *P. laurifolium*, intro. from Trinidad, appears to be this species.

mölle, Bertol. GÜISARO. SOUR GÜISARO. GUAYABA ACIDA. Shrub or small tree, of rather slender growth, the young branchlets, peduncles, and lower surfaces of the lvs. reddish velvety: lvs. oblong-oval, 3-5 in. long, the apex obtuse, apiculate, base obtuse or shortly acute, rigidly chartaceous, light green, puberulent above: peduncles erect, 3-fld.; ovary 4-locular: fr. globose, about 1 in. thick, pale yellow when fully ripe, with whitish pulp containing many rather small seeds. The flavor is acid and not especially agreeable. S.

Mex. and Cent. Amer.—This species has been offered in Fla. for years but has never been extensively planted. It is fairly hardy, and has been grown in Calif. It fruits very prolifically, its season being late summer.

AA. Branchlets terete.

Araca, Raddi. BRAZILIAN GUAVA. ARAÇÁ DO CAMPO. Large shrub, the young branchlets hirsute: lvs. oblong-oval, large, obtuse, subvelutinous above, pubescent below, the veins reticulate, somewhat raised: peduncles axillary, 1-3-fld.: fr. ovoid or oblong, yellow, sweet only when fully ripe. Common on the dry uplands of Brazil.—The species disseminated in Calif. by Franceschi under the name of *P. Araca* does not agree with this description; it is a plant strongly resembling *P. Cattleianum* var. *lucidum*, but with broader and somewhat thicker lvs., the frs. usually larger, of a deep yellow color, with few seeds and a more prominent calyx.

Cattleiänium, Sabine. STRAWBERRY GUAVA. Shrub or small tree, up to 20 ft. high, the bark smooth, green-

ish brown, the branchlets glabrous: lvs. obovate-elliptic, acute at apex and acute to cuneate at base, 2-3 in. long, glabrous, thick and coriaceous, dark green, almost glossy: peduncles axillary, 1-fld.; calyx-tube turbinate, 4- or 5-lobed, the lobes broadly oblong; petals obovate, thin; style slender, stigma peltate; ovary 4-locular: fr. obovate to roundish, $1\frac{1}{2}$ -1 in. long, purplish red, with a thin skin and soft flesh, white toward the center, containing numerous hard seeds; flavor sweet and aromatic, sometimes likened to that of the strawberry, whence the common name. Brazil.—It flowers in late spring and ripens its fruits in Sept. and Oct. This species is extensively cult. in Calif., being harder than most others, and is also grown in Fla. Var. *lucidum*, Hort., the yellow strawberry guava, usually listed by the trade as *P. lucidum*, differs in the color of its fr., which is sulfur-yellow. It is thought to be somewhat more delicate in flavor, but is less commonly grown in both Fla. and Calif. than the type. Plants intro. under the names of *P. chinense* and *P. sinense* have proved to be nothing more than this variety.

A species intro. by Franceschi under the name of *P. acre*, Ten., resembles *P. Cattleianum* var. *lucidum*, but has more elongated and usually larger frs. The foliage is of the same type.—*P. dichotomum*, Weinm., is properly *P. Araca*: a species intro. by Franceschi as this species is evidently something else, having broad coriaceous, glabrous lvs. and somewhat resembling *P. Cattleianum* in habit.—*P. guayabita*, A. Rich., is a species recently intro. from W. Cuba, where it grows wild: the frs. are small and not considered very

valuable.—*P. guianense*, Pers., is a synonym of *P. fluviatile*, Rich., a species with branchlets terete, glabrous; lvs. oval, glabrous; pedicels opposite, 1-fl. Cayenne.—*P. guineense*, Swartz, is a synonym of *P. Araca*, Raddi, according to Berg, but DeCandolle considers it a distinct species. He distinguishes it from *P. Araca* by the lvs. less soft, glabrous above, with the nervation not raised as in the latter. More recently Urban uses it in preference to *P. Araca*, which latter is made a synonym; he states that it resembles *P. Guajava*, but is easily distinguished by the less numerous transverse veins, not impressed above. Swartz, in describing *P. guineense*, stated that it came from Afr., and was cult. in Santo Domingo, but as all psidiums are now known to be American, he was doubtless mistaken regarding its origin.—*P. littorale*, Raddi, intro. by Franceschi, resembles *P. Cattleianum* very closely, but has lvs. somewhat more attenuate toward the base, and obovate or pyriform frs. Berg (in Linnaea, xxvii) groups this species, *P. Cattleianum* and *P. humile* together under the name of *P. variabile*. S. Brazil.—*P. montanum*, Swartz, is a species from the mountains of Jamaica, with 4-angled branchlets; lvs. oblong-oval, acuminate, glabrous; peduncles many-fl.; fr. subrotund.

F. W. POPENOE.

PSILOSTRÔPHE (Greek, *naked bud*, referring to the naked receptacle). Syn. *Riddellia*. *Compósitæ*. Low and corymbosely branched woolly perennial herbs with alternate and spatulate or linear lvs., the cauline entire, and with small heads of yellow fls., the ligules large in proportion, pale or whitish in age and thin-papery; achenes narrow, terete, obscurely striate and angled. About 7 species, N. Amer. *P. tagetina*, Greene (*Riddellia tagetina*, Nutt.). Loosely or somewhat villosly lanate, fairly widely branched; radical and even lower cauline lvs. often laciniate-pinnatifid; heads numerous, mostly cymosely clustered. W. Texas, E. Colo. and Ariz.—Intro. in botanic gardens abroad.

PSOPHOCÁRPUS (Greek, *noise* and *fruit*, referring to the fact that the pods when gathered and laid in the sun, blow up and explode with a noise). *Leguminosæ*. Tall twining herbs, with large tuberous roots, one of which is used as a vegetable in subtropical gardening; lvs. 3-foliolate, stipellate; stipules fastened above the base; fls. rather large, lilac; calyx with the 2 upper teeth connate; corolla much exserted, standard sub-orbiculate, wings obliquely obovate, keel obtuse, incurved; stamens monadelphous, the upper free downward; ovary stipitate; pod square, with a distinct wing to each angle.—About 5 species, Trop. Afr. and Asia.

tetragonólobus, DC. GOA BEAN. Root large, annual: sts. weak, wide-twining, glabrous; lfts. entire, ovate, acute, 3-6 x 2-6 in.: racemes lax, few-fl.; pedicels elongated; fls. large, light blue; calyx glabrous, lateral teeth oblong, lowest shorter and deltoid; pod 6-9 x 1 in., the wings $\frac{1}{8}$ - $\frac{1}{4}$ in. broad, usually much crisped and toothed. India.—Also grown in tropical and subtropical regions for the young tubers which are eaten raw or cooked, and for the young pods which are an excellent vegetable.

F. TRACY HUBBARD.

PSORÀLEA (Greek, *warty*; referring to the glandular dots which occur on the plants). *Leguminosæ*. SCURFY PEA. Herbs, shrubs, or subshrubs useful as border plants.

Usually copiously sprinkled with resinous black or pellucid dots and strongly scented: lvs. pinnate or trifoliate, rarely unifoliate; stipules free or adnate to the petiole; fls. in racemes or spikes, axillary or terminal, blue, purple, or white; calyx not enlarged after flowering, unequally 5-lobed; standard ovate or orbicular, clawed, wing oblong or falcate, keel incurved, obtuse, dark-colored; ovary sessile; pod ovoid, short, indehiscent, 1-seeded.—About 115 species common in the tropics and subtropics of both hemispheres, over 30 species in N. Amer. The genus comprises both greenhouse and hardy plants, some annual, others biennial, and still others perennial. The shrubby kinds are prop. by cuttings of half-ripened shoots, the herbaceous species by divisions when the new growth begins. The S. African species thrive in well-drained sandy peat, the others in ordinary garden soil.

A. *Plants hardy in the N.*

B. *Number of lfts. 7.*

subacaulis, Torr. & Gray. Perennial herb, stemless or nearly so, about 1 ft. high, with numerous, usually purple fls. in ovate or oblong, dense spikes; lfts. 7, digitate, obovate-oblong, 1 in. long; fl.-st. longer than lvs., rigid. April-June. Rocky hills, Tenn.

BB. *Number of lfts. 3.*

C. *Lvs. digitately compound.*

lanceolata, Pursh. Perennial herb, much branched, glabrous or nearly so, densely dark-glandular, 1-2 ft. high; lfts. sessile, bright green, entire, linear or oblanceolate; fls. bluish white, 3 lines long. June, July. Kans to W. Canada west to Wash., etc. B.B. 2:281.

CC. *Lvs. pinnately compound.*

physodes, Douglas. Perennial herb, slender, 1-2 ft. high; lfts. ovate, about 1 in. long; fls. in short, close racemes; calyx $\frac{1}{4}$ in. long, becoming enlarged and inflated until nearly $\frac{1}{2}$ in. long; corolla $\frac{1}{4}$ in. long, white or purplish. Mountains of coast ranges, Calif.

BBB. *Number of lfts. 5.*

esculenta, Pursh. POMME BLANCHE. Hardy herbaceous perennial 4-18 in. high; lfts. 5 and digitate, short-stalked, oval or obovate, entire, obtuse, narrowed at base, 1-2 in. long; fls. bluish; spikes dense, $1\frac{1}{2}$ -3 in. long; root large, often clustered, starchy. June. Prairies, Man. and Dak. south. B.B. 2:284.—The following points, by Sprague, on the pomme blanche (also called prairie apple, prairie turnip, and Indian or Missouri bread-root) are taken from Goodale's Wild Flowers of America: "In the autumn the top of the plant dies and separates from the root, near the ground, and is blown about the prairies. After the top has gone the root cannot be readily found, and hence the Indians dig them in August for their winter use. The root lies deep in the ground and is about the size of a hen's egg. The outside is covered with a thick integument almost as tough as wood and of a dark brown color. The inside is whitish and not unlike a chestnut in appearance and taste, but not so sweet. The Indian women dig the roots with great facility by means of a pointed stick 2 or 3 feet long." The roots are spindle-shaped or turnip-shaped. If the Indians use them immediately, they generally roast them in ashes. They are also dried and stored for winter, and when wanted they are mashed between stones, mixed with water and baked into cakes over the coals. The root was frequently found in the canoes of the Indians by early travelers before the plant which produced it was known to white men. Nuttall wrote: "The taste is rather insipid, but not disagreeable either raw or boiled. Texture laminated, always tenacious, solid and never farinaceous." In 1846 the pomme blanche was proposed as a substitute for the potato. Its claims to consideration were discussed in several publications, with the result that it was thought to offer no possibilities of advance over the potato.

AA. *Plants tender.*

B. *Number of lfts. 3.*

C. *Habit herbaceous.*

bituminosa, Linn. Perennial herb, $1\frac{1}{2}$ -3 ft. high, appressed hirsute; lfts. nearly entire; lower ones ovate, obtuse; upper ones much narrower, acute; peduncles longer than lvs.; fl.-heads dense, involucre, becoming elongated in fr.; fls. nearly 1 in. long. Spring and early summer. Poor soil, Arabia.

CC. *Habit shrubby.*

glandulosa, Linn. Petioles scabrous; lfts. 3, digitate, ovate-lanceolate, acuminate; fls. blue and white, in usually axillary racemes. Chile and Peru. B.M. 990.

BB. Number of lfts. 7-11.

pinnata, Linn. Arborescent or shrubby, 6-12 ft., densely branched and leafy: lfts. 7-11, pinnate, linear or lanceolate-linear, acute, commonly 10-15 lines long by about 1 line wide: fls. axillary, solitary or clustered, sessile or pedicelled, blue with white wings. S. Afr. G.C. III. 5:693; 33:301. J.H. III. 33:591. G.M. 46:611.

3248. *Psychotria undata*.
($\times \frac{1}{2}$)

affinis, Eckl. & Zeyh. (*P. pinnata* var. *subglabra*, Harv.). Shrub, to 10 ft., with 4-angled branches with resinous glands: lvs. odd-pinnate; lfts. opposite, 3-4-paired, linear, acute, dotted with black glands: fls. solitary, axillary, clustered at the ends of the branches; corolla blue with a dark purple keel-tip. S. Afr. B.M. 8331.—Only distinguished from *P. pinnata* by technical characters, principally the longer peduncles of *P. affinis*. Long grown in gardens under the name of *P. pinnata*.

F. W. BARCLAY.

F. TRACY HUBBARD.†

PSYCHOTRIA (Greek, *life-preserving*; referring to medicinal properties). Incl. *Grumilea* and *Gloneria*. *Rubiaceae*. Shrubs or small trees or rarely herbs, erect, climbing or twining, suitable for the warmhouse.

Leaves opposite, rarely whorled, with deciduous or persistent stipules: infl. terminal or rarely axillary corymbose cymes, or occasionally fascicled in the axils or capitate; fls. greenish white, yellow or rose; calyx short-tubed, limb rarely persisting; corolla-tube usually short or straight, elongate limb 5- or rarely 4- or 6-lobed; ovary 2-celled: fr. a berry or small drupe with 2 small hemispherical stones.—Over 500 species in the tropics and subtropics, frequent in Amer. Only occasionally cult.

A. Fls. yellow.

capensis, Vatke (*Grumilea capensis*, Sond.). An evergreen shrub or tree with shining lvs. 3-5 $\times$ 1½-2 in., and fls. in trichotomous, pedunculate corymbs: stipules coriaceous, broad: pedicels appressed, hairy, bracteate at the base; ultimate pedicel bearing a 6-12-fld. umbel; calyx ½ line long; corolla 3 lines long, yellow: fr. black. S. Afr. B.M. 7916.—Cult. in S. Fla.

AA. Fls. white.

undata, Jacq. Fig. 3248. A glabrous shrub: lvs. papery, elliptical, cordate-veiny; stipules large, connate,

sheathing half-way, obovate: panicle sessile, trichotomous, much exceeded by the lvs.; fls. clustered, white; corolla-lobes shorter than tube. Bahamas, Jamaica.

jasminiflora, Mast. (*Gloneria jasminiflora*, Lind. & André). Shrubby: bark whitish: lvs. 3 in. long, coriaceous, pale beneath; nerves obscure: fls. white, 1-1¼ in. long. Brazil. G.C. II. 12:201. B.M. 6454. G. 34:275 (as *P. jasminoides*).—Offered in England.

F. TRACY HUBBARD.†

PTERÓXYLON (Greek, *sneeze-wood*, so called because the wood causes sneezing). *Meliaceae*. Small tree or shrub with bitter bark, whose wood has a commercial value.

Leaves odd-pinnate; lfts. unequal-sided, 5-8 pairs: infl. axillary, panicle racemes crowded at the ends of the branches; fls. polygamous-dioecious, small, white or yellowish; sepals 4, short, obtuse; petals 4; disk hypogynous, glandular; stamens 4, alternate with the petals; ovary obcordate, 2-celled, ovules solitary: fr. a compressed, 2-celled, 2-seeded caps., bi-lobed at the apex and cordate at base.—One species in S. Afr. extending into Trop. Afr.

obliquum, Radlkf. (*P. utile*, Eckl. & Zeyh.). **SNEEZEWOOD**. A tree 20-30 ft. high: lvs. opposite; lfts. ovate-oblong, obtuse, mucronulate: racemes shorter than the lvs.—Said to grow up to 50 ft. with a trunk 2-4 ft. diam. and a beautiful crown. The wood is extremely heavy and hard, strong and close-grained, very durable in contact with the ground and easily split. Among its uses are for piles of bridges and jetties, fence-posts and recently for wood-engraving. It is said to turn readily even when green and to take a fine polish like mahogany. The seeds have short vitality.

F. TRACY HUBBARD.†

PTÉLEA (Greek name of the elm tree, transferred to this genus on account of the similarity of the fruits). *Rutaceae*. **HOP TREE**. Ornamental woody plants grown for their handsome foliage and also for their attractive light green fruit.

Deciduous shrubs or small trees: lvs. alternate,

3249. *Ptelea trifoliata*, the hop tree, in fruit. ($\times \frac{1}{4}$)

castipulate, 3-5-foliate; lvs. entire or crenulate, pinnate with petioled dots; fls. small, polygamous in terminal corymbose loose of the minute calyx, petals and stamens 4-8; ovary flattened, 2-seeded with short style; fr. a 2-seeded, indurated, small, flattened nut, furnished usually with a broad thin wing.—Usually 5 to 7 species distributed from Lake Ont. to Fla. and N.

3250. *Ptelea aptera*.

Max. are recognized, but recently about 60 species have been distinguished by Greene. Bark and foliage are sometimes used medicinally and emit (as well as the fr.) when bruised a strong, pungent odor resembling somewhat that of the hop, for which the fr. are said to have been used as a substitute—hence the name hop tree.

The hop trees are ornamental shrubs or small round-headed trees with long-petioled leaves and greenish white flowers, followed by flattened usually broadly winged and nearly orbicular fruits. The one species chiefly cultivated is a hardy North—if it proves tender as it sometimes does, it is probably raised from southern seed—and is a small round-headed rather loosely branched tree with glossy green foliage, adorned in fall with numerous clusters of light green fruits which form a pleasing contrast with the dark green foliage and remain on the branches for some time after the leaves have fallen. It thrives best in a porous moderately moist soil and prefers a somewhat shaded position. Propagation is by seeds sown in fall; the varieties by layers or by grafting in spring under glass or budding in summer on seedlings of the type.

trifoliata, Linn. Hop Tree. WATER ACH. Fig. 3249. Shrub or small round-headed tree, attaining 25 ft.; lvs. 3, sessile, ovate to elliptic-oblong, narrowed at both ends, sometimes acuminate, the lateral ones unequal at the base, crenulate or entire, dark green and hirsute above, pale below, glabrous or pubescent when young, 3-5 in. long; fls. $\frac{1}{4}$ - $\frac{1}{2}$ in. across; filaments villous below; fr. about 1 in. long, broadly winged. June. Ont. and N. Y. to Fla., west to Minn., and sometimes escaped from cult. elsewhere. S.S. I: 33, 34. G.C. III. 15: 375. Several varieties are in cult., of which var. *aurea*, Bohnsch (P. aurea, Hort.), the GOLDEN HOP TREE, with yellow foliage, is the best known. Var. *glabra*, Kirchn. Lvs. grayish green, pubescent when young. Var. *mollis*, Torr. & Gray (P. mollis, Curtis. P. tomentosa, Raf.).

Branchlets, inf., and lvs. beneath pubescent or tomentose. N. C. and Fla. to Ariz. More tender than the northern glabrous form and rarely cult.

aptera, Parry. Fig. 3250. Shrub. to 15 ft.; lvs. 3, sessile, the terminal one elliptic-obovate or obovate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, the lateral ones smaller, obscurely crenulate, pubescent; clusters few-fld.; fr. broadly ovate, turgid, wingless or nearly so, $\frac{1}{4}$ - $\frac{1}{2}$ in. long. Low. Calif. G.F. 3: 333 (adapted in Fig. 3250).—Possibly cult. in Calif.; not hardy North.

ALFRED REHDER.

PTERIDIUM (Greek, with the form of *Pteris*). *Polypodiaceae*. Large ternately divided ferns commonly known as BRACKEN or BRAKES, with the sporangia borne on a marginal line-like receptacle as in *Pteris* (Fig. 3251) and covered with a marginal indusium, but with an additional membranous indusium within the receptacle. Commonly known as *Pteris*.

aquilinum, Kunth. Lvs. scattered from an underground rhizome, 2-9 ft. high, ternately compound. Fields and waste places, in some of its forms throughout the world.—In some parts of the world it is used as food, in New Zeal. especially. It is counted a weed in the western states and a Farmers' Bulletin mentions methods of eradicating it.

L. M. UNDERWOOD.

PTERIDOPHYLLUM (Greek, fern leaf, referring to the pinnate lvs.). *Papaveraceae*. Perennial acaulescent herbs with a rather thick prostrate rhizome; roots fibrous; lvs. all radical, petiolate, pectinate-pinnatifid; scapes naked, longer than the lvs.

with a simple or at base subramose many-fld. raceme; sepals 2, deciduous, very short; petals 4, deciduous, elliptic-concave; stamens 4, deciduous; ovary orbicular, 1-seeded, 2-4-seeded; fr. unknown. One species, Japan, *P. racemosum*, Sieb. & Zucc. A small glabrous herb with narrowly obovate lvs. 4-6 in. long, about 1 in. broad; segms. oblong-linear, rounded at the apex; scape slender, 6-9 in. tall, bearing a loose raceme of small white fls. Intro. into botanic gardens abroad; probably not otherwise cult.

3251.

Fruiting pinnule of common brake.—*Pteridium aquilinum*. (Natural size.)

PTERIS (Greek name for a fern, from a word meaning wing; alluding to the prevalence of pinnate forms). *Polypodiaceae*. A large genus (60 species) of widely distributed ferns with sporangia borne on a marginal line-like receptacle that connects the free ends of the veins, and with the more or less altered margin of the leaf rolled over to form a continuous indusium. Many of the forms are among the commonest species of ferns in the trade and are very generally used for table decoration, especially as small plants for fern-dishes. For culture, see *Fern*.

The common brake, *P. aquilina*, Linn., is by some authors now referred to a separate genus; see *Pteridium*, above.

Pteris probably contains as many cultivated forms as *Nephrolepis*, but in America at least does not rank with the fern in importance in the trade. As pot-plants for the house, the species *cristata* and *serrulata* and their varieties will probably succeed as well as most of the *nephrolepis* forms, and better than some. They are, however, extremely uncommon, except as already noted, as small plants for fern-dishes. Apparently only one dealer in America makes a specialty of growing *pteris*. His list is given at the end of this article.

A. Veins free throughout.

B. Lvs. simply pinnate, the lower pinnæ not divided.

1. *longifolia*, Linn. Lvs. 1-2 ft. long, 4-9 in. wide, lanceolate, often narrowed below; pinnæ 20-30 on each side, linear, entire. Tropical regions all around the world, extending to S. Fla. Var. *Mariesii*, Hort. Fronds shorter and pinnules straighter, the plant keeping closer to the pot; a good horticultural form.

BB. Lvs. simply pinnate, but the lower pinnæ forked.

2. *cretica*, Linn. Fig. 3252. Lvs. 6-12 in. long, on slender, straw-colored stalks, consisting of a terminal pinna and 2-6 opposite sessile pairs, the upper often decurrent, the lower pairs cleft nearly to the base into 2 or 3 pinnules. Quite generally distributed in tropical regions, extending to Cent. Fla. Many varieties are in cult., of which var. *albo-lineata*, Hort. (Fig. 3253), is one of the finest, with broader pinnæ and a broad, central, whitish band. Var. *major* and var. *nobilis* are larger horticultural forms, and var. *magnifica*, Hort., and var. *Mayii*, Hort. (*P. Mayii*) are still more developed. Var. *Wilsonii*, Hort., Fig. 3252, is one of the common garden forms.

3. *serrulata*, Linn. f. Lvs. 3-12 in. long, on slender brownish stalks, consisting of a terminal pinna and 5-6 pairs of lateral ones, the upper ones decurrent and the lower forked into 2 or 3 branches or with second branch above the basal one; pinnæ narrow, the indusium not

3252. *Pteris cretica* var. *Wilsonii*.

extending to the apices, which are sharply serrulate. China and Japan.—Many monstrous and distorted forms appear in cult., giving rise to such varietal horticultural names as *angustata*, *cristata*, *cristata nana compacta*, *cristata variegata*, *densa*, *Gilbertii*, *Ouvrardii* (*P. Ouvrardii*, Hort.), *voluta*, and the like, but these cannot be regarded as true varieties in any scientific sense.

4. *ensiformis*, Burm. Lvs. of two sorts, the sterile with elliptic or elliptic-lanceolate segms. the lower pinnæ 5-7-parted, the upper gradually simpler: sporophylls similar but taller and with longer and much narrower divisions. India to Polynesia; often confused with the preceding species, as both are more or less common in cult. Var. *Victòriæ* (*P. Victòriæ*, Hort.) is a garden variety with lvs. variegated with white.

BBB. Lvs. with lowest pinnæ pinnate.

5. *inæqualis*, Baker. Lf.-blades ovate-deltoid, 18-24 in. long, 10-15 in. wide, with 4-5 pairs of pinnate or pinnatifid pinnæ followed by 2-3 pairs of broadly linear simple ones and ending in a long, terminal, irregularly pinnatifid portion; divisions of the lower sides of the pinnæ uniformly much longer and larger than the upper ones. China and Japan.

6. *semipinnata*, Linn. Lvs. 12-18 in. long, the upper portion simply pinnate with decurrent pinnæ, the 4 or more lowest pinnatifid on the lower side, the upper side of the secondary rachises bordered by a narrow lamina. India, China, Japan, and E. Indies. Var. *Bausei*, Hort. (*P. Bausei*, Hort.), is a garden form.

BBBB. Lvs. with lowest pinnæ bipinnatifid.

c. Lowest pinnæ enlarged.

7. *quadriaurita*, Retz. Lvs. up to 2-3 ft. long, on strong, pale stalks, with a terminal pinna cut down to the rachis into numerous linear-oblong lobes, and below this several similar pinnæ on each side, the lowest of which are usually again compound with similar but smaller ones branching from the lower side at base. All tropical regions. Var. *argyræa*, Hort. (*P. argyræa*, Moore) is a form with a white band down the centers of the pinnæ. Var. *tricolor*, Hort. (*P. tricolor*, Lind.), is similar but has a tinge of red in addition.

8. *heterophylla*, Linn. Lvs. 6-8 in. long, on pale stalks, of two sorts; sterile lvs. elliptic, deeply incised; fertile lvs. narrowly linear-elliptic, with broad indusia and sterile apices ending in 2-3 teeth; both sorts bipinnate in the lower portions. W. Indies to Brazil. Sometimes referred to a distinct genus, *Anopteris*. Var. *internata* (*P. internata*, Moore) is a garden variety with smaller sporophylls and broader segms.

9. *tremula*, R. Br. Lf.-blades 2-4 ft. long, on polished chestnut-brown stalks; upper pinnæ simply pinnate, lower often much compound: sori copious, sometimes filling up the whole segm. except the rachis. Austral., New Zeal.—Many forms occur in cult., as var. *Smithiana* (*P. Smithii*, Hort.), *variegata*, and the like.

cc. Lowest pinnæ not enlarged.

10. *scabérula*, Richard. Lf.-blades 12-18 in. long, on brownish scabrous stalks, lanceolate-ovate in outline, tripinnate or quadri-pinnatifid throughout; rachis flexuous, scabrous; sori at maturity covering nearly the entire surface of the narrow lanceolate segms. New Zeal.

AA. Veins free, except for a single low arch next the midvein.

11. *biaurita*, Linn. (*P. maxima*, Baker. *P. nemoralis*, Willd.). Lf.-blades 15-30 in. long, with a terminal pinna 6-9 in. long, cut into narrow round-pointed divisions on 7-10 pairs of similar lateral ones, the lowest pair bearing a fork on the lower basal side. All tropical regions.—Habit very like *P. quadriaurita*, from which it differs chiefly in the venation. Var. *cristata* (*P. maxima* var. *cristata*, Hort.) is a cult. form.

12. *Wallichiana*, Agardh. Lf.-blades tripartite, with the lateral divisions again forked, the central one reaching 2 ft. long, with numerous lanceolate sessile opposite pinnules, cut again into numerous narrow lobes $\frac{1}{2}$ in. wide. India, Japan, and the Philippine Isls. Known also as *Campteria Wallichiana*.

AAA. Veins uniting, forming copious meshes.

13. *leptophylla*, Swartz. Lf.-blades triangular, 9–12 in. each way, on straw-colored stalks; upper pinna simple, those below pinnatifid to a winged rachis, the lowest similarly bipinnatifid at the base; veins fine: sori not reaching the tips of the segms. Brazil. Known also as *Lilobrochia leptophylla*.

3253. *Pteris cretica* var. *albo-lineata*.—One of the standard house ferns.

Besides those already given, there are a number of forms the exact relationship of which has not been ascertained, and a few forms often listed under *Pteris* which belong properly under other generic names. These undetermined and transferrable names mentioned in North America are: *P. adiantoides*, Hort.; *P. chinensis*, possibly a variety of *P. serrulata*; *P. geraniifolia*, see *Doryopteris*; *P. hastata*, see *Pellaea viridis*; *P. palmata*, see *Doryopteris*; *P. metallica*, Hort.; *P. Summarsi*, Hort.; *P. plumosa*, Hort.; *P. regina*, Hort.

The following list contains forms of *Pteris* actually in the American trade. It represents the list of forms which are being or have been grown by H. A. Dreer, and is arranged in the order of the commercial importance of the varieties named. The writer is indebted to J. C. Clark, of Dreer's, for the information. It will be noted that there are several forms which have not already been described. The numerals are given for purposes of identification and they refer to the numbers of the species described in this article.

Wilsonii, 2.
cretica albo-lineata Alexander, 2.
cretica Ouvardi, 2.
Wimsettii Distinction, 2.
Wimsettii Dutrei, 2.
Wimsettii Gautherii, 2.
Wimsettii grandis, 2.
Wimsettii tripartita, 2.
Wimsettii Sieboldii, 2.
Wimsettii rivertoniana, 2.
Wimsettii multiceps, 2.
Childsii, 2.
fiabellata, 6.
Grevilleana variegata, Hort.
leptophylla argentea, 13.

Discarded varieties (by Dreer)

biaurita.
nemoralis variegata, 11.
tricolor.
cretica Drinkwaterii, 2.
cretica Harrisonii, 2.
longifolia.
longifolia Mariesii.
metallica, Hort.
Summersii, Hort.
tremula Smithiana.
Wimsettii, 2.

P. Wilsonii, Hort. (Fig. 3252), represents about half the total sales. *P. Childsii* (G. 37: 293) is an important form, but it produces no spores, and therefore can be reproduced only by division. *P. Wimsettii rivertoniana* is a new form intro. in 1915 which shows considerable promise. Numbers of other forms of *Pteris* may be expected to appear in the trade.

L. M. UNDERWOOD.
R. C. BENEDICT.†

PTEROCÁCTUS (*wingcactus*). *Cactaceæ*. Low cacti, with numerous slender round sts.; fr. a caps.; seeds flat, winged. Three species described, all from Argentina, little cult. *P. Kuntzei*, Schum. Roots several, tuber-like: branches glaucous: spines 9–12, minute, appressed: fls. yellow, terminal. J. N. ROSE.

PTEROCÁRPUS (Greek, *wing fruit*; the pods are girded by a broad wing). *Leguminosæ*. Trees or woody climbers without prickles: lvs. alternate, uneven-pinnate; lfts. alternate or irregularly opposite, without stipules: fls. yellow, rarely mixed with violet and white, often showy, in axillary or terminal racemes; calyx turbinate; standard orbicular or broad-ovate, wings obliquely obovate or oblong, keel with its petals resembling or shorter than the wings, free or shortly connate; stamens all connate in a sheath slit above, or both above and below, or the upper one free; ovary sessile or stipitate: pod compressed, indehiscent, orbicular or broad-ovate.—About 45 species, natives of the tropics of both hemispheres. The following species may be in cult. in some greenhouses: *P. Dräco*, Linn., growing 30 ft. high, native of Trop. Amer. *P. indicus*, Willd., "Burmese rosewood," growing about as high, but a native of the E. Indies. *P. Marsupium*, Roxbg., a pale yellow-fl. tree reaching a height of 40 ft. Coromandel. *P. Röhrrii*, Vahl, from Trop. Amer., which grows to be 20 ft. high.

PTEROCARYA (Greek, *pteron*, wing, and *karya*, nut; referring to the winged nuts). *Juglandaceæ*. Ornamental trees grown for their handsome pinnate foliage and the attractive pendulous racemes of winged fruits.

Deciduous: branches with lamellate pith; winter buds naked or scaly, more or less stalked and usually several in each axil, one above the other: lvs. alternate, exstipulate, odd-pinnate, with almost sessile lfts.: fls. monocious, in pendulous catkins, appearing with the lvs.; staminate catkins rather dense, fls. consisting of 3 connate bracts, 1–4 sepals and 6–18 stamens; pistillate catkins slender, the 1-celled ovary inclosed in a connate involucre elongated into a 4-toothed beak; stigmas 2: fr. a small 1-seeded, winged nut, 4-celled at the base. In germination the 4-lobed cotyledons are borne above the ground and become green, while in *Juglans* and *Carya* they remain inclosed in the nuts.—Eight species: 6 in China, 1 in Japan, and 1 in W. Asia.

The pterocaryas are handsome trees of rapid growth usually dividing into several stems from the base, with large pinnate leaves, rather inconspicuous flowers appearing with the foliage and adorned in summer and fall with long drooping racemes of winged fruits. They thrive best in rich and moist soil, but grow well also in drier localities. *P. fraxinifolia* and *P. rhoifolia* are hardy as far north as Massachusetts, but need some protection while young. *P. stenoptera* is more tender and the other Chinese species have not yet been sufficiently tried. Propagation is by seeds sown in autumn or stratified, also by layers and suckers.

A. Winter buds naked, usually several in each axil.

B. Fr. with 2 distinct wings.

C. Wings of fr. suborbicular: rachis of lf. terete, glabrous.

fraxinifolia, Spach (*P. caudésica*, C. A. Mey. *P. Spachiana*, Lav.). Tree, to 60 ft., with spreading branches, often rising in several sts. from the ground: young branchlets slightly pubescent: lvs. 8–15 in. long, lfts. 11–25, ovate-oblong to oblong-lanceolate, acute or acuminate, serrate, pubescent only in the axils of the veins beneath, 2–4 in. long: stamens 10–16: fr. including the semi-orbicular wings, $\frac{1}{2}$ – $\frac{3}{4}$ in. broad, in racemes to 18 in. long. W. Asia. Gn. 34, p. 219; 62, p. 235. G.C. III. 4: 381. G.W. 9, p. 10. L.I. 20, 21. Var. *dumôsa*, Schneid. (*P. dumôsa*, Lav.). More shrubby: lfts. smaller, about 2–2½ in. long. Seems more tender.

hupehensis, Skan. Tree, to 60 ft.: branchlets glabrous or sparingly hairy: lfts. 5-9, oblong to oblong-lanceolate, acuminate, rounded at the base, serrate, glabrous above, bearded in the axils of the veins beneath, 3-5 in. long: racemes to 18 in. long, glandular: fr. including the suborbicular wings 1-1½ in. across. Cent. China.

cc. *Wings oval to oblong-lanceolate, longer than broad: rachis more or less winged.*

Rehderiana, Schneid. (*P. frazinifolia* × *P. stenoptera*). Fig. 3254. Tree, similar to *P. frazinifolia*: rachis of lf. narrowly winged, the wings not serrulate and often wanting between the lower lfts.; lfts. 11-25, oblong to oblong-lanceolate, serrate, acute or acuminate, pubescent in the axils beneath, 2-4 in. long: frs. with oval or oval-oblong wings about ½ in. long. S.T.S. 2: 137.—Originated at the Arnold Arboretum and surpasses both parent species in vigor and hardiness.

stenoptera, DC. (*P. sinensis*, Hort. *P. japonica*, Hort.). Tree, to 60 ft.: young branchlets villous: lvs. 6-12 in. long, with the rachis distinctly winged and

3254. *Pterocarya Rehderiana*. (× ¼)

pubescent beneath; the wings often serrulate; lfts. 11-21, oblong, acute, serrate, pubescent beneath on the midrib, 2-4 in. long: stamens 6-10: fr. with oblong or oblong-lanceolate, usually upright wings diverging at a narrow angle. China. L.I. 19.

BB. *Frs. winged all around.*

Paliurus, Batal. Tree, to 60 ft.: branchlets pubescent while young: lfts. 7-9, oblong-ovate to oblong-lanceolate, acuminate, serrate, the midrib beneath and also the rachis pubescent, 3-6 in. long: racemes with pubescent rachis: fr. suborbicular or oval, winged all around, glabrous, 1½-2½ in. broad. Cent. China. J.H.S. 28, p. 65.

AA. *Winter buds covered with 2-3 dark brown, large scales, falling off early in spring: accessory buds wanting.*

rhoifolia, Sieb. & Zucc. (*P. sorbifolia*, Sieb. & Zucc. *P. laevigata*, Hort.). Tree, attaining 80 ft., with spreading branches: branchlets glabrous: lvs. 8-15 in. long, with terete pubescent or almost glabrous rachis; lfts. 11-21, oblong or oblong-lanceolate, acuminate, pubescent on the veins beneath or almost glabrous, 2-4 in.

long: fr. with a broad rhombic wing, about 1 in. across. Japan. S.Z. 2:150. S.I.F. 1:16.—This species is an important forest tree in Japan and has proved hardy at the Arnold Arboretum.

ALFRED REHDER.

PTEROCÉLTIS (Greek, *pteron*, wing; referring to the winged fr. and the close affinity of the tree to *Celtis*). *Ulmaceae*. A deciduous tree from N. W. and Cent. China, in foliage and habit very much like *Celtis*, but with a winged fr., resembling a small elm fr. Cult. and prop. like *Celtis*; probably hardy as far north as Mass. The only species is *P. Tatarinowii*, Maxim. Tree, to 50 ft.: branchlets glabrous: lvs. ovate to ovate-oblong, acuminate, broadly cuneate at the base, irregularly and sharply serrate, 3-nerved at the base, glabrous, 1½-3½ in. long: fr. axillary, solitary, slender-stalked, suborbicular, often broader than high and the wing usually emarginate at the apex.—Rare in cult. and without particular ornamental qualities.

ALFRED REHDER.

PTEROCÉPHALUS (Greek, *wing head*, so named because the head appears covered with a lot of feathers after the fls. fall off). *Dipsacaceae*. Herbs, half-shrubs and shrubs, annual or perennial: bracteoles narrow: involucre mouth short, ciliate, pubescent; calyx-limb 12-24 long bristles; corolla 5-fid; mostly without palea. About 20 species chiefly in the Medit. region but also in Asia. This genus was formerly included in *Scabiosa* but is now kept distinct. *P. Parnassii*, Spreng. (*Scabiosa Pterocéphala*, Linn.). A densely tufted perennial with woody sts. and branches, procumbent: lvs. narrowed into the stout petiole, ovate, obtuse, deeply crenate-toothed or lyrate-pinnatifid: heads depressed-hemispherical; fls. lilac-pink; corolla 2-lipped, upper 2-lobed, lobes short rounded; lower 3-lobed, lobes ovate, obtuse. Greece. B.M. 6526. Perfectly hardy in England, used for carpeting in the herbaceous border or suitable for rockwork.

PTERODÍSCUS (Greek, *wing* and *disk*, having reference to the wings of the disk of the fr.). *Pedaliaceae*. Perennial succulent herbs: st. tuberous at the base: lvs. opposite or alternate, coarsely dentate to pinnate-laciniate, rarely subentire: fls. solitary, short-pedicelled in the lf.-axils, yellow or purple; calyx small, 5-parted; corolla-tube funnel-shaped, oblique or slightly gibbous at base, limb somewhat 2-lipped, lobes subequal, orbicular; ovary 2-celled, cells undivided: fr. indehiscent, laterally compressed, with 4 longitudinal wings, unarmed. About 15 species in Trop. and S. Afr. *P. speciosus*, Hook. St.-base globose: st. densely glandular, 3-6 in. high: lvs. rather numerous, crowded in the upper part of st., linear to linear-oblong: calyx-segms. lanceolate, acuminate; corolla bright red-purple: fr. suborbicular, cordate at base. Trop. and S. Afr. B.M. 4117. G.Z. 21, p. 49. *P. luridus*, Hook. f., having dull yellow fls. and a native of S. Afr., is also occasionally cult. B.M. 5784.

PTEROLÒBIUM (Greek, *wing* and *pod*; the pods are produced into a wing at the extremity). *Leguminosae*. Woody climbers having the habit of *Cæsalpinia*, from which they differ only in the pod: lvs. bipinnate; lfts. small, numerous; stipules small or inconspicuous: fls. small, white, racemose, the racemes in lax panicles at the tips of the branches; calyx deeply cleft, lobes imbricated; petals spreading, oblong and clawed; stamens 10, free, declinate; ovary sessile, 1-ovuled: pod indehiscent, with a large horny oblique wing. About 7 species in the tropics of the Old World. *P. indicum*, A. Rich. (*Cæsalpinia lacerans*, Roxbg.). Branches slender, finely downy and with minute prickles: lvs. alternate with 8-16 pinnæ, 12-16 lfts., pale green: racemes copiously panicked at the end of the branches; calyx with the lowest sepal longest; corolla yellow, not showy. Old World tropics.—Has been

intro. into England and is occasionally cult., the treatment being the same as that given *Cæsalpinia*. The species varies in the size of the lvs. and in the width and size of the wing of the pod.

PTERONIA (Greek, *wing*, referring to the chaffy receptacle). *Compósitæ*. Small dry or glutinous shrubs: lvs. opposite or rarely alternate, mostly entire, glabrous or hairy, often ciliate; heads terminal, solitary or corymbose; involucre scales scarious, often shining; fls. yellow, rarely purple. About 60 species, natives of S. Afr. *P. incana*, DC., a scrubby divaricate branched bush with the twigs and lvs. thinly tomentose-canescens: lvs. opposite, sessile, linear-oblong, obtuse; heads sessile, 6-9-fld., golden yellow, involucre scales oblong, subobtusate, at first greenish yellow then fulvous and finally the centers brown: achenes top-shaped, densely and rigidly hairy. B.M. 8380.—Occasionally cult. abroad.

PTEROSPÉRMUM (Greek, *wing seed*; referring to the fact that the seeds are winged). *Sterculiáccæ*. Scaly or stellate-tomentose trees or shrubs, suitable for the greenhouse and outdoors in the southern part of the country.

Leaves 2-ranked, leathery, simple or lobed: infl. 1-3 axillary and terminal peduncles, 1- or few-fld.; fls. often elongated; calyx tubular, 5 more or less connate sepals; petals 5, deciduous with the calyx; staminal column short, bearing opposite the sepals 3 linear 2-celled anthers between each part of 5 anti-petalous ligulate staminoides; ovary inserted within the top of the staminal column: caps. woody or coriaceous, terete or 5-angled.—About 25 species, confined to Trop. Asia. Pterospermums are said to need considerable warmth, and perfect drainage is most essential. They grow best in a mixture of sandy, fibry loam and lumpy peat. Prop. by cuttings of half-ripened side shoots, cut close to the st.

acerifolium, Willd. Large tree: lvs. 10-14 x 6-12 in., roundish or oblong, often lobed, palmately 5-7-nerved; nerves prominent beneath: bractlets lacinate: fl.-buds oblong, obtuse, 5-angled, rusty tomentose: fls. 5-6 in. across, pure white, fragrant; sepals linear-oblong, thick; petals linear-oblong: caps. 4-6 in. long, 5-celled; seeds many; wing large, thin. B.M. 620. G.W. 7, p. 121.—Cult. in S. Calif.

F. TRACY HUBBARD.†

PTEROSTYLIS (Greek, *wing column*; the column is broadly winged). *Orchidææ*. Terrestrial herbs with small underground tubers: radice\ lvs. ovate; st.-lvs. developed and linear or lanceolate, or reduced to scarious sheathing scales: fls. usually green, often tinged red or brown, large and solitary or smaller and several in a raceme; dorsal sepal broad, erect, incurved and very concave; petals lanceolate-falcate, attached to the basal projection of the column; labellum on a short claw at the end of the basal projection of the column, movable; column with a pair of hatchet-shaped or quadrangular wings.—About 50 species, mostly Australian but a few in New Zeal. and New Caledonia and 1 in New Guinea. *P. curta*, R. Br. Lvs. in a radical rosette, usually on long petioles, ovate or broadly elliptical, 5-9-nerved: scapes 1-fld.; usually about 6 in. high; galea erect, acute; lip linear, obtuse, entire, rather longer than the column; wings of the column with the lower lobe long and obtuse, the upper lobe short and broad. Austral. B.M. 3086. O. 1910:104. Cult. to some extent in greenhouses abroad as are the following: *P. acuminata*, R. Br. Austral. B.M. 3401; *P. Banksii*, R. Br. New Zeal. B.M. 3172; *P. Baptistii*, Fitzg. Austral. B.M. 6351; and *P. nutans*, R. Br. Austral. B.M. 3085. They are prop. by division and thrive in lf.-mold lightened by a little sand; the lower third of the pots should be filled with broken crocks.

F. TRACY HUBBARD.

PTEROSTYRAX (Greek, *pteron*, wing; alluding to the winged or ribbed fruit, by which it is distinguished from the allied genus *Styrax*). *Styracææ*. Ornamental woody plants grown chiefly for their drooping panicles of white flowers.

Deciduous trees or shrubs, stellate-pubescent: lvs. alternate, denticulate: fls. in large panicles, terminal on short branchlets; calyx 5-toothed; corolla 5-parted almost to the base; stamens 10, somewhat longer than the corolla and slightly exceeded by the slender style; ovary 3-celled: fr. a ribbed or winged 1-2-seeded nut.—Three species in China and Japan. Sometimes united with *Halesia*, from which it is distinguished chiefly by the panicle drooping infl. and the 5-merous fls.

These are handsome trees or shrubs with rather large light green leaves and white flowers in showy pendulous panicles, followed by small rather inconspicuous fruits. They are only precariously hardy in sheltered positions as far north as Massachusetts. In June they are very attractive, with their graceful drooping panicles of numerous deutzia-like fragrant flowers. They thrive best in a moderately moist sandy loam and are propagated by seeds or layers and also by greenwood cuttings under glass.

3255. *Pterostyrax hispida*. (× 1/3)

hispida, Sieb. & Zucc. (*Halesia hispida*, Mast.). Fig. 3255. Tree, attaining 50 ft., with slender spreading branches forming an open head: lvs. short-petioled, ovate to oblong, narrowed at the base, acute or acuminate, denticulate, almost glabrous or pubescent on the veins beneath, light green above, grayish green beneath, 3-7 in. long: panicles 5-10 in. long; fls. creamy white, fragrant, about 1/2 in. long: fr. 10-ribbed, thickly covered with bristly hairs, 1/2 in. long. June. China, Japan. G.C. II. 22:177; III. 46:88; 48:125. Gn. 8, p. 243; 26, p. 23; 34, p. 111. R.H. 1875, p. 308. G.F. 5:389. M.D.G. 1899:353. G.W. 3, p. 37. F.E. 14:36 (pl. 21); 17:457. B.M. 8329. S.I.F. 2:65. G.M. 57:538.

corymbosa, Sieb. & Zucc. (*Halesia corymbosa*, Nichols.). Small tree or shrub: lvs. short-petioled, oval or ovate, abruptly acuminate, serrulate with usually bristly teeth, sparingly stellate-pubescent on both sides, 2 1/2-4 1/2 in. long: panicle corymbose 3-5 in. long: fr. with 4-5 narrow wings, tomentulose, 1/2 in. long. June. China, Japan. S.Z. 1:47. S.I.F. 2:65.—Seems to be more tender than the preceding species and is but rarely cult.

ALFRED REHDER.

PTYCHOCOCCUS (Greek, *fold* and *grain*, probably referring to folds on the fruit). *Palmaceæ*. Separated from *Ptychosperma* by technical characters of the endocarp of the seed. Two species, New Guinea. *P. paradoxus*, Becc. (*Ptychosperma paradoxus*, Scheff.). St. simple, 9–12 ft. high, rather slender, covered with dense white arachnoid tomentum: lvs. at top of st. regularly pinnate-divided; segms. 6–15, in young plants subsemi-rhomboid, later broad-lanceolate, contracted toward the base, tip oblique-truncate: fls. dioecious; ovary ovate-conical, 1-celled; seed 5-sulcate.

PTYCHORAPHIS (Greek, *folded* and *rape*). *Palmaceæ*. Malayan and Indian palms grown in warm greenhouses.

Stems slender, ringed: lvs. pinnate, the lfts. long-acuminate: spadix from between the lvs., much branched, the spirally arranged fls. usually staminate only toward the apex.—Three species, one from Singapore, 1 from the Philippines and 1 from Nicobar. The genus is placed next to *Rhopaloblaste* by Drude in Engler and Prantl's *Natürlichen Pflanzenfamilien* and distinguished by the ridge of the forked raphe and deeply ruminant seed, while the rumination of the upper parts of the seed is flattish. Cult. as for any tropical palm, requiring abundance of moisture.

augusta, Becc. Trunk becoming 80–100 ft. high in the wild, much lower in cult., slender, smooth: lvs. 6–10 ft. long; pinnæ 1–2 ft., linear, acuminate, bright green: spadix much branched, 2½–3 ft. long: fr. elliptical-oblong, red; seed grooved on one side. Nicobar. G.W. 2, p. 198.—Wm. Watson writes: "It is as graceful as *Cocos Weddelliana* or *Geonoma gracilis*, and it grows as freely under cult. as either of these popular palms." This rare palm has been offered in Amer., but is not known to be cult. at present.

Siebertiana, Hort. Sts. slender: lvs. copper-colored when young, afterward rich green; petioles colored with small brownish scales; lfts. 10 in. long, ¾ in. broad, tapering to a long thread-like point. Malaya. G.C. III. 43: suppl. Apr. 25. Gng. 16:278. G.W. 13, p. 31.—An elegant species resembling a *kentia*. N. TAYLOR.†

PTYCHOSPÉRMA (Greek words, probably referring to the ruminant albumen of the seed). *Palmaceæ*. A small and unimportant group of palms little known in America.

Trunks smooth, ringed, crowned at the summit by a dense cluster of pinnately divided lvs.: lfts. acuminate, either entire or jagged at the apex: spadix simple or sometimes branched, appearing below the lvs.: fls. monœcious in the same spadix: fr. an ovoid drupe. For cult., see *Archontophoenix*, to which belong many of the plants in the trade under *Ptychosperma*. For *P. elegans*, consult *Seaforthia*.

Macarthurii, H. Wendl. Described as dwarf, and most cult. specimens are so; in nature 20–30 ft.: lvs. pinnate, the lfts. arching, from 3–9 in. long, usually obliquely cut at the apex: infl. unknown. Austral. G.Z. 23, p. 265.—Suckers freely from the base, thus making a bushy plant.

P. alba, Scheff.—*Dictyosperma alba*.—*P. Alexandræ*, F. Muell.—*Archontophoenix Alexandræ*.—*P. Cunninghamiana*, H. Wendl.—*Archontophoenix Cunninghamii*.—*P. elegans*, Hort.—*Seaforthia*.—*P. Rumphii*—*Drymophloeus*.—*P. Selmanii*—*Balaka*.

N. TAYLOR.

PUCCOON: *Lithospermum*. P., Red: *Sanguinaria*. P., Yellow: *Hydrastis*.

PUERARIA (M. N. Puerari, botanist of Geneva). *Leguminosæ*. Twining herbs or shrubs, often climbing; grown for ornament.

Closely allied to *Dolichos* and *Phaseolus*, but differing among other things in the beardless style, tumid nodes of the racemes and monadelphous stamens: lvs. 3-foliate and stipellate, the lfts. sometimes lobed: fls. often large, pea-shaped, in long and dense, often

compound, racemes; standard usually spurred at the base, about equaling the wings and keel: pod flattish, linear, many-seeded.—Eleven species, Asian and Milanesean.

A. Lfts. not deeply lobed.

B. Pod not constricted.

hirsuta, Schneid. (*P. Thunbergiana*, Benth. *Dolichos japonicus*, Hort. *Pachyrhizus Thunbergianus*, Sieb. & Zucc.). KUDZU VINE. Perennial, with large tuberous starchy roots, making a vigorous growth of slender, hairy, twining sts.: lfts. rhombic-ovate to nearly orbicular-ovate, variously lobed, but the margins entire and ciliate: fls. pea-shaped, purple, in axillary spikes late in the season, not showy: pod large and flat. Japan and China. A.G. 13:387; 21:505. G.F. 6:505. R.H. 1891, p. 31. Gt. 45:1429. Gn. 61, p. 161. G.W. 5:605.—A hardy vine remarkable for the great rapidity of its growth, and most useful for covering arbors and verandas. It is also used as a forage plant. From a well-established root, vines will grow 40–60 ft. in a single season, producing a profusion of very large lvs. In the N. the plant dies to the ground in the winter, but in the S. the top becomes woody. The large fleshy root assumes most curious shapes, the main branches often being 4–5 ft. long. Georgeson writes of the plant in Japan: "The roots are fleshy and yield starch of excellent quality; the tough fiber of the inner bark is manufactured into a sort of cloth which combines fineness with remarkable strength; and in certain situations the vine is unparalleled for ornament and shade." The fls. are borne on the old or woody sts., but these sts. usually do not persist north of Philadelphia, and even rarely there. With age, the tops are more likely to survive the winter. Prop. by division of the roots, or by seeds when they can be had; also by cuttings.

BB. Pod constricted.

tuberosa, DC. (*Hedysarum tuberosum*, Roxbg.). Root tuberous, very large: st. shrubby: branches finely grayish pubescent: stipules minute, deciduous, ovate-cordate: lfts. membranous, roundish, 6–12 in. long, glabrescent above, below densely covered with a whitish appressed pubescence: fls. in slender, dense, often panicle racemes 6–9 in. long; pedicels very short, densely fascicled; calyx ½–¾ in. long, densely silky; teeth rather obtuse, shorter than the tube; corolla bluish, not twice as long as the calyx; limb of standard orbicular, distinctly spurred: pod 2–3 in. long, membranous, flat, 3–6-seeded, clothed with long, gray, silky bristly hairs. India. Wright, *Icones*, 412.—Intro. into U. S. in 1911. Suitable as an ornamental for the southern parts of the United States. The root contains a saccharine matter, an easily oxidizable resin; and a resin acid. It is also said to be used as a food and in medicine in India. When cut, the root exudes a bitter, acrid, opalescent gum.

AA. Lfts. usually deeply lobed.

phaseoloides, Benth. (*Dolichos phaseoloides*, Roxbg.). St. twining, often scarcely woody, clothed with dense spreading brown hairs: stipules small, lanceolate: lfts. membranous, sparingly covered with appressed bristly hairs above, gray and densely matted below; terminal lft. roundish, broadly ovate or rhomboidal, entire or shallowly or deeply lobed, 3–6 in. long: fls. clustered on numerous long-peduncled racemes; pedicels very short; bracts and bractlets lanceolate, strongly nerved, more or less persistent; calyx ¼–½ in. long, densely clothed with appressed bristly hairs, lowest tooth lanceolate, as long as the tube, others shorter, all setaceous pointed; corolla reddish, twice as long as the calyx; standard roundish above, distinctly spurred: pod glabrescent, 3–4 in. long. India, China, Malaya.—Intro. into U. S. in 1911. Suitable as an ornamental in the southern states.

P. L. RICKER.

PULMONARIA (Latin, *lung*; the herb having been considered a remedy for diseases of the lungs). *Boraginaceæ*. **LUNGWORT**. Perennial herbs with a creeping rootstock, used in flower-gardens and hardy borders.

Leaves radical, often broad, cauline few and alternate; fls. in terminal cymes, rather large, blue or purple; calyx tubular-campanulate, 5-toothed or cleft to the middle only; corolla-tube straight, naked or pilose, limbs spreading, 5-lobed; stamens included in the tube; nuts smooth.—About 8–10 species in Eu. and 1 species said to extend into N. Asia. *Mertensia*, an allied genus, has a short open more deeply-cleft calyx, exserted, stamens, and slightly fleshy nuts.

Pulmonarias are of easy cultivation, preferring light soil, not very dry, in open or partially shaded positions. They are readily propagated by division. Divide the clumps every two or three years.

A. *Lvs. white-spotted.*

B. *Plant very glandular.*

saccharâta, Mill. **BETHLEHEM SAGE**. Height 6–18 in.: st. setose-hairy, with articulate glands; radical lvs. oval-acuminate at both ends, slightly decurrent, larger than in following species; fls. whitish or reddish violet. April, May. In shady places, Eu. G. 29:147.

BB. *Plant rough-hairy but slightly if at all glandular.*

officinalis, Linn. (*P. maculata*, F. G. Dietr.). Height 6–12 in.: radical lvs. in distinct tufts, ovate-oblong to nearly linear, on long footstalks, coarsely hairy, more or less spotted; fls. in terminal forked cymes, red fading to violet. April. Woods, Eu. Gn. 74, p. 213.—Commonly cult.

AA. *Lvs. entirely green.*

B. *Radical lvs. linear- or oblong-lanceolate, tapering to the petiole.*

angustifolia, Linn. Height 6–12 in.: st. setose-hairy, having a few glands; radical lvs. linear-lanceolate to oblong-lanceolate, gradually tapering to and decurrent on petiole; fls. blue. April, May. Woods, Eu. Var. **azûrea**, Hort., has been listed.

BB. *Radical lvs. broadly elliptic-lanceolate, abruptly contracted into the petiole.*

montana, Lej. (*P. mollis*, Wolff, not Auth.). Height 6–20 in.: lvs. bright green, radical broadly elliptic-lanceolate, abruptly contracted to the petiole; fls. violet. April. Cent. Eu.—Some of the material cult. as *P. mollis* and its varieties is probably not the *P. mollis* of Wolff and is referable to *P. officinalis*.

P. alba, Hort. Saul., is presumably *Mertensia sibirica* var. *alba*.—*P. aernensis*, Hort., with purple-blue fls. and compact growth, and its var. *alba*, Hort., with pure white fls., and good green lf., flowering in March, are listed.—*P. sibirica*. See *Mertensia sibirica*.—*P. virginica*. See *Mertensia virginica*.

F. W. BARCLAY.

F. TRACY HUBBARD.†

PULSATILLA: *Anemone*.

PULTENÆA (probably named after Dr. Richard Pulteney, 1730–1801). *Leguminosæ*. Shrubs suitable for the warmhouse, not commonly in cultivation, although many species have been occasionally grown.

Leaves alternate or rarely ternate-verticillate; fls. axillary and solitary or in terminal heads, usually yellow, orange or mixed with purple; ovary sessile or rarely short-stipitate; pods ovate, compressed or turgid, 2-valved.—About 90 species in Austral. *Pulteneas* grow best in a mixture of peat and silver sand and are said to need firm potting and careful watering with soft water. Prop. by seed or by cuttings made of the points of shoots when about three parts matured.

rösea, F. Muell. Erect heath-like shrub with virgate branches; lvs. linear-terete; stipules subulate-pointed; fls. pink, in terminal heads; calyx silky pubescent; pod acuminate. Austral. G.Z. 21:193.

PUMMELO (possibly contraction of Dutch *pompelmoes*). A generic term including most of the varieties of *Citrus grandis* (see page 782, Vol. II), other names for forms of this species being grapefruit (page 1391, Vol. III) and shaddock (Vol. VI).

The grapefruits long grown in the West Indies and the United States comprise a group of very juicy subglobose (not pear-shaped) thin-skinned varieties differing widely from the common pummelos of the East Indies which are usually more or less pear-shaped, thick-skinned, and have a firm pulp. These latter are called shaddocks in the West Indies and United States. These two extremes are well separated in the character of the fruit and also show differences in the leaves and twigs, the pummelos having more or less hairy twigs, leaves downy on the under surface and very broadly winged petioles, while the grapefruits have nearly smooth, slender twigs, leaves smooth on the under surface, and narrower petioles.

In the Orient, however, there are a multitude of forms of pummelos, among which occur all the intermediates between the two extreme types noted above. Under these circumstances it seems advisable to retain the word pummelo in its usual East Indian sense, i. e., to include all varieties of *Citrus grandis* with the exception of the grapefruit group which is sufficiently distinct to merit a separate name. The attempt was made some years ago to apply the name pomelo to the grapefruit in this country but this name never attained any currency among growers, shippers, dealers, and consumers and was largely restricted to books and bulletins on descriptive horticulture. Pomelo is really a variant of pummelo, also written pummelow, pummeloe, pummalo, pumelo, pomello, and so on. In view of this confusing perplexity of similar names, it seems inadvisable to attempt to distinguish by the name pomelo the grapefruit of America from the pummelo of the East Indies.

As a result of a trip to Japan, China, and the Philippine Islands made by the writer in 1915, it was found that some varieties of pummelos were very resistant to citrus canker (caused by *Pseudomonas citri*), unlike the grapefruit which is very susceptible to this disease. Unless citrus canker can be wholly eradicated from the southeastern United States it will be necessary to hybridize the grapefruit with the most canker-resistant sorts of citrus fruits in the hope of securing new varieties combining the juiciness and high flavor of the grapefruit with the canker-resistance of the other parent. In this work the canker-resistant varieties of the pummelo, some of them of excellent quality, promise to be of capital importance.

In view of this unforeseen importance of the pummelo, the following sketch of the more promising known varieties is given:

Malayan varieties.—**Banda navel**, from Plo-ay, Banda Islands, Malaysia. Fruits very large, nearly round but bumpy, growing in clusters of five or six; peel an inch thick; pulp white, juicier and sweeter than the common pummelo, nearly or quite seedless; the fruits sometimes show an included navel, a smaller fruit the size of a peeled orange being formed near the top of the larger fruit. Navel fruits are very rare in seedlings grown in Amboyna from seed brought from Banda. This very interesting variety described by Rumphius about 200 years ago does not seem to have been noticed since.—**Cassomba**. Rumphius describes this as a depressed globose variety as large as a man's head, commonly grown on the island of Amboyna. It has red vinous pulp as sweet as currants when ripe, often seedless.—**Labuan**, or **Bali** (?). A seedless pummelo of very superior quality is said to have been introduced by Sir Hugh Low from the island of Bali to Labuan Island off the coast of Borneo, from whence it was sent some fifteen years ago to the West Indies. The tree is said to be thornless.

Indian varieties.—*Bombay Red.* Fruit subglobose, 7 inches diameter; skin $\frac{1}{4}$ – $\frac{1}{2}$ inch thick; pulp very juicy, deep red (color of raw beef), pleasantly subacid, with a characteristic flavor. This is said by E. E. Bonavia to be "by far the finest variety of pummelo" he had seen. He describes a number of other sorts varying in shape, size, color, and juiciness. The leaves and twigs of some varieties are smooth; of others downy or hairy. In 1904 a collection of thirteen sorts of Indian pummelos was received by the Department of Agriculture from the Botanic Garden at Calcutta. A number of these have fruited both in California and Florida. One of these Indian pummelos (shown in Fig. 3256) was grown at Eustis, Florida, in 1915, and has pink flesh.

Siamese varieties.—The Siamese seedless pummelos, grown in the Nakon chaisri district, have long been

of Japan: *Hirado.* Large, depressed globose, about 4–5 inches in diameter and 3–4 inches high, with grapefruit-like smooth skin of lemon-yellow color; pulp juicy, rind thin, segments regular, core rather small, very good flavor; seeds small but numerous. This variety originated at Hirado near Nagasaki, Japan, some seventy-five years ago as a seedling of a pummelo brought from Java. The writer saw bearing trees of this variety at the Nagasaki agricultural experiment station in 1915 and found the fruits to be juicy and of excellent quality and noted that the tree remained almost entirely exempt from citrus canker (caused by *Pseudomonas citri*) which was attacking seriously Washington navel orange trees grown only a few yards distant. On account of its superior quality and high degree of canker-resistance, hybrids were made in June, 1915, between it and American grapefruit by means of pollen shipped from Florida to Nagasaki in vacuum tubes (Science N.S. 42:375–377. Sept., 1915). It is hoped to secure in this way canker-resistant hybrids equal to the grapefruit in quality. Seedlings of the Hirado pummelo are now being grown by the Department of Agriculture.—*Ogami*, vicinity of Kagoshima; rare; very large, very flat; rind smooth; thin, pinkish; core large, segments numerous, sometimes twenty-five, pulp pinkish, fine-grained, juicy, very good quality; seeds numerous.—*Hata-jirushi*, experiment farm of Count Tachibana, Yanagawa, Fukuoka-ken. A very large flat pummelo like the Ogami, very much like the latter in general characters but rind much thicker and pulp vesicles coarser, good-flavored; seeds numerous.—*Yoko-jirushi*, experiment farm of Count Tachibana, Yanagawa, Fukuoka-ken. A large round variety with rough skin; oil-glands remarkably large and prominent, not much rag, segments regular, pulp slightly pinkish, good quality, vesicles long and parallel; seeds numerous.—*Take-jirushi*, experiment farm of Count Tachibana. Long-oval in shape, with salmon-colored flesh, segments large and rather irregular, very sweet and of good quality; seeds few.—*Tamura.* Shinkai-mura, Kôchi-ken; a round, smooth-skinned variety, with pale pink flesh, segments irregular, large, pulp coarse-grained and good quality; seeds very few.

Formosan varieties.—*Matô.* Matao, Ensui-kô-chô, Formosa. Common; fruit small, conical; rough-skinned, rind very thin; core small, pulp similar to the Ogami, very high quality; practically seedless; very early ripening. Besides the Matô pummelo, red (*To yu*) and white (*Pei yu*) pummelos of fairly good quality are commonly grown in Formosa.

Chinese varieties. *Canton varieties.*—There are at least half a dozen varieties grown about Canton. The Sung-ma is one of the best for export. The sorts commonly exported are pear-shaped, with a very fragrant thick peel and a very firm greenish yellow pulp of aromatic flavor. These pummelos are exported to all parts of the world where Cantonese Chinese live.—*Amoy*, a very large slightly pear-shaped pomelo with a thick skin and very firm white flesh, is produced near Amoy. In spite of its reputation it is of mediocre quality.

California seedlings.—There are many pummelo trees in northern California grown from seeds planted years ago by the Cantonese Chinese immigrants. Until a few years ago Canton pummelos were regularly imported by Chinese merchants in San Francisco. G. P. Rixford has located two score or more seedling trees in California which show considerable variation in the size, color, shape, and quality of the fruit. Some are of fairly good quality. These seedlings are mostly old bearing trees and furnish excellent opportunity for crossing with grapefruit in the hope of securing canker-resistant hybrids.

Florida shaddock.—In Florida, pummelos have been grown for a long time under the West Indian name shaddock. The grapefruit is so much better, however,

3256. Pummelo. (Branch and fruit $\times \frac{1}{4}$; details $\times \frac{1}{2}$)

famous and have recently been studied there by H. H. Boyle (Phil. Ag. Rev. 7:65–9, pls. 3, 4, Feb., 1914. Journ. Heredity, 5:440–7, pls. 1–3, Oct., 1914). *Oval Nakon chaisri.* The best variety is slightly oval, $4\frac{1}{2}$ inches diameter, 4 inches high; skin pale yellow; flesh white, juicy, aromatic, not bitter; seeds few or none. Boyle considers this variety superior to any other pummelo and to any grapefruit and says it is a good fruit for market purposes.—*Flat Nakon chaisri.* A very flat fruit, $4\frac{1}{2}$ inches diameter, $3\frac{1}{4}$ inches high; skin bright yellow; flesh white, juicy, aromatic; seeds few or none. Boyle considers this an excellent fruit for market purposes. Two other seedless varieties, but of somewhat inferior quality, were found by Boyle.

Japanese varieties.—In Japan many varieties of pummelos, there called Buntan, Uchimurasaki or Jabon are known, variously estimated from 75 to 200. The following are among some of the more promising studied by T. Tanaka in the course of a survey of the citrus fruits

that shaddocks have almost disappeared. H. H. Hume lists only two varieties, the *Mammoth*, oblate, 5-6 inches diameter, flesh firm, white, sweetish, bitter; and the *Pink*, oblate-pyriform, 6 x 6½ inches, flesh rough, pink, bitterish, subacid. Other forms are occasionally found but almost all are of very poor quality.

Hybrids.—Natural hybrids of the pummelo are common in Japan. They are mostly between the pummelo and the Mandarin types of oranges. Some are of great promise, however, being large, juicy, and very good-flavored. The common *Natsu mikan*, a very flat fruit 4-5 inches diameter, 2½-3 inches high, ripening very late in the season, is probably one of these hybrids. This group of hybrids is very similar to the tangelo, obtained by crossing the grapefruit with oranges of the Mandarin type. In India there seem to be natural hybrids between pummelos and lemons or citrons; possibly the group of citrous fruits called *Amilbed* by Bonavia is of this nature. After discovering that some varieties of pummelos are very resistant to citrus canker, the author inaugurated in 1915 in Japan a series of experiments in hybridizing the Florida grapefruit with different varieties of Japanese pummelos in the hope of securing canker-resistant grapefruit-like hybrids, as was noted above under *Hirado pummelo*.

Sour pummelos.—In India and other eastern countries very large acid-fleshed pummelos occur which are said to yield up to a quart of juice. One such sour pummelo grown near Eustis, Florida, has been used in breeding new types of acid fruits by hybridizing.

WALTER T. SWINGLE.

PUMPKIN AND SQUASH. Fruits, and the plants that produce them, of species of *Cucurbita*, used for food when cooked and also for stock-feed. See *Cucurbita*.

In North America, the word pumpkin (colloquially but incorrectly pronounced *punkin*) is applied to large late-maturing globular or oblong fruits of forms of *Cucurbita Pepo*, represented in the "field pumpkin" (Fig. 3257), from which pies are made and which is commonly fed to cattle and swine. The pumpkin is characterized by a five-angled stem which is not expanded where it joins the fruit (Fig. 1133, Vol. II), by rough vines and herbage, and by prominently lobed leaves. Sometimes the word is applied to some of the

3257. Connecticut or common field pumpkin.—*Cucurbita Pepo*.

earlier forms of this species, as to the Sugar pumpkins that ripen late in summer or early in autumn and are used for pies. It is also applied to forms of *Cucurbita moschata*, which, in the form known as Canada Crookneck squash, is sometimes called "pie pumpkin."

The word squash is adapted from an American Indian word, and is applied in an indefinite way to various members of the genus *Cucurbita*. The application of the name does not conform to the specific lines of the plants. What are called summer squashes

are mostly varieties of *Cucurbita Pepo*, of the Crookneck and Pattypan type. The winter squashes are either *C. maxima* or *C. moschata*, chiefly the former. If the name squash belongs to one species more than to another, this species is probably *C. maxima*. This species produces fruit with very firm or "solid" yellow flesh. The pictures on pages 909-911 in Vol. II, show some of the forms of these species. Fig. 3258 is the Winter or Canada Crookneck, one of the forms of *C. moschata*. Figs. 3259-3262 are forms of the multifarious *Cucurbita Pepo*. A further discussion of the application of the vernacular names will be found in Vol. II, page 909.

3258. Winter or Canada Crookneck squash.—*Cucurbita moschata*.

Culturally, the pumpkins and squashes comprise one group of warm-season frost-sensitive plants. They are very easy to grow, provided they are given a warm and quick soil. They are long-season plants (except the "bush" varieties of summer squash), and therefore in the North they are very likely to be caught by frosts before the full crop has matured, unless the plants are started early and make a rapid and continuous growth. In hard rough clay lands the plants do not get a foothold early enough to allow them to mature the crop. On such lands it is impossible, also, to plant the seeds early. As a consequence, nearly all squashes are grown on soils of a loose and relatively light character. Sandy lands or sandy loams are preferred in the northern limits, but an open clay loam is probably the best soil in general for these plants. On very rich bottom lands the plants often thrive remarkably well, but there is danger that they may run too much to vine, particularly when the soil has too much available fertilizer. In order that the plants shall start quickly, it is necessary that the soil be in excellent tilth. It is customary, with many large growers, to apply a little commercial fertilizer to the hills to give the plants a start. A fertilizer somewhat strong in nitrogen may answer this purpose very well; but care must be taken not to use nitrogen too late in the season, else the plants will continue to grow over-vigorously rather than to set fruit.

Pumpkins and squashes are of two general kinds, so far as culture is involved, the bush varieties and the long-running varieties. The bush types are usually early. The vines run very little, or not at all. The various summer squashes belong to this category, and most of them are varieties of *Cucurbita Pepo*. The hills of bush varieties are usually planted as close together as 4 by 4 feet. On high-priced land they are often planted 3 by 4 feet. The fruits are borne close to the center of the plant. The long-running varieties comprise the autumn and winter types; and to this category may also be referred, for cultural purposes, the common field pumpkins. There is much difference between the varieties as to length of vine. On strong soils, some varieties will run 15 to 20 feet, and sometimes even more, producing the fruit some feet from the hill or the root. These varieties are planted from 8 to 12 feet apart each way. Sometimes they are planted in corn-fields, and they are allowed to occupy the ground after tillage for the corn is completed, but with the introduction of corn-harvesting machinery this practice is falling away.

For general field conditions, the seeds of pumpkins and squashes are usually planted in hills where the plants are to stand. If the land is mellow and rich, these hills are nothing more than a bit of ground 12 to 18

inches across, that has been freshly hoed or spaded and leveled off. On this hill, from six to ten seeds are dropped, and they are covered an inch or less in depth. In order to provide the seeds with moisture, the earth is usually firmed with the hoe. When the very best results are desired, particularly for the home-garden, hills may be prepared by digging out a bushel of soil and filling the place with rich earth and fine manure.

3259. Summer Crookneck squash.—*Cucurbita Pepo* form.

It is expected that not more than three to five of the plants will finally be left to each hill; but there are many contingencies to be considered. The young plants may be taken off by cutworms or by other insects, or they may be caught by frost, and it is well not to remove the extra plants too soon.

If it is necessary to start the crop in advance of the season, the seeds may be planted in pots or boxes in a forcing-house or hotbed about three weeks before it is time to set them in the field. If the seeds are started much earlier than this, the plants are likely to get too large and to become stunted. When set in the field, the roots should fill the pot or box so that the earth is held in a compact ball, and the plant should be fresh, green, and stocky. Sometimes the seeds are planted on sections of inverted tough sod, and the entire piece is transferred directly to the field. Plants that become stunted and develop one or two flowers when they are in the box are usually of little use. Sometimes seeds are planted directly in the field in forcing hills, and when the plants are established and the season is settled the protecting box is removed and the plants stand in their permanent positions.

A good vine should produce two or three first-class fruits; if, however, one flower sets very early in the season, the vine may devote most of its energies to the perfection of that single fruit and not set many others, or may set them too late to allow them to mature. If it is desired, therefore, that the plants shall produce more than one fruit, it is advisable to pick off the first fruit, providing it sets long in advance of the appearance of

3260. Summer Bergen squash, a form of *Cucurbita Pepo*.

other pistillate flowers. These remarks apply particularly to winter squashes in northern regions. With small varieties and under best conditions, as many as a half-dozen fruits may be secured from a single vine, and in some cases this number may be exceeded. Squash vines tend to root at the joints; but so far as general culture is concerned, this should be prevented, because it tends

to prolong the growing season of the vine, although it may have to be encouraged if the borer is prevalent. It is usually well, therefore, to lift the joints occasionally when hoeing, although the vine should not be moved or disturbed. This precaution applies particularly in the short-season climates of the North, where every effort must be made to cause the plant to set its fruit early in the season and to complete its growth before cool weather.

Tillage is simple. It consists in light working of the surface until the plants begin to run strongly, after which the big weeds are pulled by hand. For early results with bush squashes, or when the land is of a cold or backward type, the plants may be grown in hills that are raised a few inches above the general level; this adds to the expense, and in most cases it is better to practise level culture.

The varieties of pumpkins and squashes are numerous, and it is difficult to keep them pure if various kinds are grown together. However, the true squashes (*Cucurbita maxima*) do not hybridize with the true pumpkin species (*Cucurbita Pepo*). There need be no fear, therefore, of mixing between the Crookneck or Scallop squashes on the one side and the varieties of Hubbard or Marrow types on the other. The summer or bush squashes are of three general classes: the Crooknecks, the Scallop or Pattypan varieties, and the Pineapple or oblong-conical varieties, all forms of *C. Pepo*. The autumn and winter varieties may be thrown into

3261. The Pineapple Summer squash, one of the Scallop, Pattypan or Custard Marrow type.—*Cucurbita Pepo*.

several groups: the true field pumpkin, of which the Connecticut Field (Fig. 3257) is the leading representative, being the one that is commonly used for stock and for pies; the Canada Crookneck or Cushman types, which are varieties of *C. moschata*; the Marrow and Marblehead types, which are the leading winter squashes and are varieties of the *C. maxima*; the Turban squashes, which have a "squash within a squash" and are also varieties of *C. maxima*. The mammoth pumpkins or squashes which are sometimes grown for exhibition and which may weigh 200 or 300 pounds, are forms of *C. maxima*.

In Europe the vegetable marrow type is much prized. It is a form of *Cucurbita Pepo*. In this country it is little grown, although it thrives well, the various summer squashes of the Crookneck and Scallop types being more popular. The following English advice on this vegetable is from a contribution to Gardening Illustrated, from which Fig. 3263, representing Moore's vegetable marrow, is also reduced: "Vegetable marrows should be eaten young—say when about one-fourth or one-sixth their full size. Cut in this state, and boiled quickly until quite tender in plenty of water, carefully strained, and served with melted butter, they are second to no vegetable that comes to table, not even excepting green peas or asparagus. Early cutting, careful cooking, and serving are the chief points to which attention should be paid; but there are others, one of the principal being rapid growth. Grow vegetable marrows quickly, and they are almost sure to be good; grow them slowly, and you will find them often tough and bitter. Hence the soil or place in which they are grown can hardly be too rich for them. Not but what they do fairly well in any

good garden soil, but the richer it is the better. On a rubbish-heap, for instance, vegetable marrows grow with wonderful vigor, and fruit abundantly." For early results, they are often started under glass in pots. There are many kinds or varieties. The custard marrows are fruits of the Scallop or Pattypan kind. The summer Crookneck is little used abroad for food.

Insect enemies and diseases of pumpkins and squashes are several. Perhaps the most serious is the striped cucumber beetle, which destroys the tender young plants. This insect is destroyed with the arsenicals applied in flour, also with tobacco powder and some other materials; but since it works on the under sides of the leaves as well as on the upper, it is difficult to make the application in such way as to afford a complete protection. The insects also are likely to appear in great numbers and to ruin the plants even whilst they are getting their fill of arsenic. If the beetles are abundant in the neighborhood, it is best to start a few plants very early and to plant them about the field in order to attract the early crop of beetles, thereby making it possible to destroy them. From these early plants the beetles may be hand-picked, or they may be killed with very heavy applications of arsenicals,—applications so strong that they may even injure the plants. Sometimes the hills of squashes are covered with wire gauze or mosquito netting that is held above the earth by means of hoops stuck into the ground. This affords a good protection from insects that arrive from the outside, providing the edges are thoroughly covered with earth so that the insects cannot crawl under; but if the insects should come through the ground beneath the covers they will destroy the plants, not being able to escape. The arsenicals should be applied when the dew is on, or the plants may be sprayed with bordeaux mixture to which the poison has been added. The squash bug or stink-bug may be handled in the same way as the striped-cucumber beetle. This insect, however, remains throughout the season and, in many cases, it is necessary to resort to hand-picking. The insects crawl under chips or pieces of board at night, and this fact may be utilized in catching them. The young bugs can be killed by tobacco extract and soap, and by some of the emulsions.

The stem-borer attacks the vines later in the season, boring into the main stalk near the root, and causing the entire plant to lose vigor or to die. It is a soft white larva. As a safeguard, it is well to cover the vines at the joints with earth after they have begun to run, so that roots will form at these places and sustain the plant if the main stem is injured. The borers may also be cut out with a thin-bladed knife. Tobacco dust is said to keep the insect away. Infected vines should be burned to destroy larvæ and eggs.

A wilt disease, caused by a species of bacillus, sometimes does damage to species of *Cucurbita*. The disease is likely to be associated with the punctures of the striped beetle. Burn the infected plants.

The summer squashes are eaten before the shell becomes hard, and not afterward. A thoroughly

with the stem on, and much care should be exercised to prevent any bruising or rough handling. In a rather dry and somewhat dark cellar, with a temperature of about 40°, such fruits may be kept all winter. Commercial growers store them in above-ground houses built for the purpose, placed only one layer deep on racks or shelves. The house is well insulated to prevent fluctuation, kept dry, and provided with a stove or other heat for very cold weather, the temperature maintained at

3263. Vegetable marrow.—*Cucurbita Pepo*.

about 40° to 45° F. The following advice on the storing of squashes was written for the "Cyclopedia of American Horticulture" by W. W. Rawson: "Cut the squashes just before they are thoroughly ripe. Be careful not to start the stem in the squash. Lay them on the ground one deep and let them dry in the sun two or three days before bringing to the building. Handle very carefully when putting in, and be sure that the wagon in which they are carried has springs. Put them two deep on shelves in a building. This should be done on a cool, dry day. If the weather continues cool and dry, keep them well aired by day; but, if damp weather comes, build a small fire in the stove in order to dry out the green stems. Keep the temperature about 50°, and air well in dry weather. The squashes may need picking over about Christmas if put in the building about October 1; handle very carefully when picking over. Fifty tons can be kept in a single building with a small fire. Do not let them freeze, but if temperature goes down to 40° at times it will do no harm; nor should it be allowed to go as high as 70°. The Hubbard squash keeps best and longest and does not shrink in weight as much as other kinds; but any of them will shrink 20 per cent if kept until January 1." L. H. B.

PUNICA (*Punicus*, Carthaginian; hence *Malum punicum*, "apple of Carthage," an early name of the pomegranate). *Punicææ*. A small branched tree, the branches rather terete and spiny. The common pomegranate of cultivation.

Leaves opposite, subopposite and fascicled in short branches: fls. in simple axillary racemes, small, white; calyx persistent, 5-7-lobed; petals 5-7; lanceolate, corrugate; ovary inferior: berry spherical, thick-skinned, many-celled.—Two species, Orient to N. W. India. For cult., see *Pomegranate*.

Granatum, Linn. **POMEGRANATE**. A large deciduous shrub or small tree, with oblong or obovate, obtuse, entire, glabrous and more or less shining lvs.: fls. orange-red, showy; calyx tubular, the short lobes persistent on the top of the fr. (as on an apple); petals inserted between the lobes; ovary imbedded in the calyx-tube (or receptacle-tube), comprising several locules or compartments in two series (one series above the other), ripening into a large, juicy, many-seeded pome-like berry. Persia to N. W. India. G.W. 10, p. 510.—A handsome plant, with showy fls. 1 in. across.

3262. The Negro squash. One of the warty forms of *Cucurbita Pepo*.

mature Crookneck or Scallop is not used and not marketable. The late forms of *Cucurbita Pepo*, like the field pumpkin, are not long keepers, but the late squashes of the *C. maxima* type, as Hubbard, Boston Marrow, and Marblehead, can be kept till late spring. To keep these late squashes, care should be taken to have them full grown, with hard shells, not frosted or otherwise injured; they should be harvested

in summer. Hardy as far north as Washington and Baltimore. It is also grown as a conservatory plant, blooming in winter as well as in summer. For ornament, the double-flowering kinds are the most popular (F.S. 13:1385, as *P. Granatum Legrellei*). There are many varieties. The treatment of the fruit-bearing varieties is discussed under *Pomegranate*. Var. *nana*, Hort. (*P. nana*, Linn.). DWARF POMEGRANATE. Seldom growing higher than a man, and usually treated as a pot-plant in the N. It is the best kind for greenhouse use. The double-fl. form is most common. B.M. 634. It is as hardy as the species, and is suitable for outdoor work where the climate is not too severe. On the Pacific Coast it is grown as a hedge-plant as far north as San Francisco. Both this and the species are easily grown by cuttings of dormant wood, as currants are, but the cuttings should be started indoors with some heat.

L. H. B.

PÛRSHIA (after F. T. Pursh, or Pursch, as is the original spelling of his name, 1774-1820; born at Grossenhain, in Saxony; traveled in this country and wrote a flora of North America). Syn., *Kúnzia*. *Rosaceæ*. Low deciduous spreading shrub, allied to *Cercocarpus*, with alternate, mostly fascicled, small, cuneate and tridentate lvs.: fls. solitary, yellowish; calyx-tube tubular; petals spatulate, 5; stamens numerous; pistils 1 or sometimes 2: fr. a pubescent leathery achene exceeding the persistent calyx. Of little ornamental value with its sparse grayish or bluish green foliage and its rather inconspicuous fls. and frs., and but rarely cult. Probably hardy as far north as Mass., requiring sunny position and well-drained soil; an excess of moisture, especially during the winter, proves fatal to it. Prop. by seeds and probably by layers. The only species is *P. tridentata*, DC. (*Kúnzia tridentata*, Spreng.). Diffusely branched shrub, attaining 5, rarely 10 ft.: lvs. cuneate-obovate, 3-lobed at the apex, whitish pubescent beneath, $\frac{1}{4}$ - $\frac{3}{4}$ in. long: fls. solitary on short branchlets, almost sessile, yellowish, about $\frac{3}{4}$ in. across: fr. ovate-oblong, acuminate. April-July. Ore. to Wyo., New Mex. and Calif. B.R. 1446. Var. *glandulosa*, Jones (*P. glandulosa*, Curran), is glandular and has very small, almost glabrous lvs., sometimes pinnately 5-lobed.

ALFRED REHDER.

PURSLANE: *Portulaca oleracea*. P., Winter: *Montia perfoliata*.

PUSCHKÍNIA (named for Count M. Puschkin). *Liliaceæ*. Hardy or half-hardy bulbous plants which may be used in the rock-garden or border.

Leaves radical, few, the first often oblong, the others linear: infl. a simple leafless scape; fls. few, blue, loosely racemose; perianth campanulate, of 6 subequal lobes; stamens 6; ovary sessile, 3-celled: caps. membranaceous, dehiscent.—Two species, Asia Minor, the Caucasus and Afghanistan. These attractive spring-blooming bulbs have clusters of small 6-lobed white fls., each narrow lobe being prettily lined with blue. A good specimen may have as many as 10 fls., each $\frac{3}{4}$ in. across. The peculiar feature of the genus is the crown on which the stamens are borne. This is a white body of petal-like texture, having 6 lobes, each of which is variously toothed. The genus is allied to *Scilla* and *Chionodoxa*.

scilloides, Adams (*Adamsia scilloides*, Willd.). Height 4-12 in.: bulb globular, about $\frac{3}{4}$ in. thick: lvs. as long as scape, $\frac{1}{2}$ -1 in. wide: raceme 1-10-fl.; pedicels slender, erect; perianth usually bluish white; divisions elliptic-oblong, three times as long as the tube; crown one-third as long as divisions, cleft to middle into truncate or retuse teeth. April, May. Var. *libanótica*, Boiss. (*P. libanótica*, Zucc.), differs from the type in having divisions of perianth $\frac{1}{2}$ in. long and the teeth of the crown more acute and bifid. Gn. 32, p. 5; 54, p. 219. B.M. 2244. F.S. 21:2220 (as *P. sicula*).

F. TRACY HUBBARD.†

PUTRANJĪVA (Indian name). *Euphorbiaceæ*. Evergreen trees, cult. for ornament in the tropics: lvs. alternate, simple: fls. small, axillary, single or in small clusters, apetalous; calyx imbricate; stamens 1-4; disk absent; styles broad, spreading; ovary 2-3-celled, 2 ovules in each cell: fr. a 2-celled drupe.—Two or more species in Trop. Asia. Related to *Drypetes*.

Róxburghii, Wall. **INDIAN AMULET PLANT.** **WILD OLIVE.** A moderate-sized tree, nearly glabrous: branches slender: lvs. short-petioled, ovate-lanceolate, serrulate, smooth, shining, 2-3 in. long: fls. yellow: fr. globose to ovoid, about $\frac{1}{2}$ in. thick, white-tomentose. India.

J. B. S. NORTON.

PÛYA (Chilean name). *Bromeliaceæ*. Large terrestrial xerophytic South American bromeliads.

Allied to *Pitcairnia* (differing in having a fully superior rather than partially superior ovary).—Forty-four species, according to Mez (DC. Monogr. Phaner. 9). For culture, see also *Billbergia*. *Puya* also includes the plants known in trade as *Pourretia*.

Puyas and *pitcairnias* are generally found in collections of bromeliads and are usually grown in moist tropical houses. The native home of the *puyas* is on the steep stony slopes of the Cordilleras at high altitudes with little other vegetation for company except some species of *cereus*. This would indicate that drier and cooler conditions, or such as are given cacti and succulents, would suit them best, yet they thrive equally well in the tropical house. Indeed, the writer has found most of the family *Bromeliaceæ* very accommodating not only to temperature and moisture conditions, but to soils and methods of growing them; for example many of the *tillandsias* may be grown on blocks of wood as epiphytes, yet they do equally well grown in pots. But what perhaps is more remarkable is the fact that several of the stronger-growing bromeliads appear to grow equally well either in a strong loamy mixture, or a mixture of chopped fern root and charcoal. The writer has pineapples growing in both mixtures with equal success. But the most rational treatment is to give all the bromeliads conditions and soil similar to the environment in which they are found in their native habitat, yet according to the experience of the writer few plants possess such remarkable adaptability to changed conditions as do these plants. (E. J. Canning.)

A. Fls. yellow.

chilensis, Molina (*Pitcairnia coarctata*, Pers., and *P. chilensis*, Lodd.). Becoming 4-5 ft. or more high, sometimes branching: lvs. in tufts, 2-4 ft. long, very narrow, often recurved, the margins armed with strong recurved spines or thorns, glaucous: blossoms in a branching, hoary, bracted infl. rising 3-5 ft. from the top of the caudex, the fls. large (2 in. across), sessile or nearly so, the 3 lanceolate sepals greenish and the obovate-oblong much-exserted petals yellow or greenish yellow, the 6 erect stamens shorter than the petals, the stigma 3-branched. Chile. B.M. 4715. F.S. 9:869, 870. J.F. 4:392. J.H. III. 62:533. G.C. III. 7:685; 48:390; 54:3.—A striking and mammoth bromeliad, making a yucca-like mass of foliage and projecting above it a very showy infl.

AA. Fls. white or rose-color.

gigas, André. Still larger than the latter, sending its titanic spikes 20-30 ft. into the air, from a rosette of hard and thick spiny-toothed agave-like lvs.: infl. simple, dense, club-shaped, terminating the tall, erect, bracted scape: lvs. green above and white beneath, the spines black and hooked: fls. white, passing into rose. Colombia, 10,000 ft. R.H. 1881, p. 315, and Gn. 21, p. 309.—Can probably be handled like agaves.

AAA. Fls. blue.

cærúlea, Lindl. (*Pitcairnia cærúlea*, Benth. & Hook.). Foliage pineapple-like, with linear very acute

lvs. 2 ft. long, which are spinose-dentate and nearly glabrous: peduncle 3-4 ft. tall, the bracts membranaceous, the infl. somewhat branched but not loose: fls. narrow-tubular, the petals blue and oblong-obtuse, the sepals much shorter and green and obtuse; alternate stamens shorter. Chile. B.R. 26:11.

alpéstris, Poepp. (*Pitcairnia cærulea*, Baker. *Puya Whitei*, Hook. f. *Pitcairnia alpéstris*, Bailey). Fl.-cluster much branched or panicle, with bracts more serrate than in *P. cærulea*: fls. very large and showy, with a flaring mouth, dull metallic blue. Chile. B.M. 5732.—A plant in bloom has the habit of a yucca. This and *P. cærulea* will probably stand considerable frost.

P. spathacea, Mez (*Pitcairnia spathacea*, Griseb.). Lvs. up to 18 in. long and 1 in. broad, the spines incurved: panicle about 2 ft. long; sepals ovate, acuminate, pale rose; petals dull blue. Argentina. B.M. 7966.—*P. violacea*, Mez. Lvs. up to 20 in. long, linear, stiff, spiny in margin: panicle 15-20 in. long; sepals green, lanceolate, 1-1½ in. long, acute; petals deep violet. Chile. B.M. 8194.

L. H. B.

GEORGE V. NASH.†

PYCNANTHEMUM (Greek, *dense and blossom*; referring to compact flower-heads). *Labiātæ*. MOUNTAIN MINT. BASIL. Hardy aromatic perennial herbs suitable for the flower-garden.

Stems corymbosely branched above: lvs. entire, glabrous or pubescent, nearly sessile: infl. dense, many-fl. whorls, crowded with bracts and usually forming terminal heads or close cymes; fls. whitish or purplish, late summer and early autumn; calyx about 13-nerved, naked in the throat; corolla short, more or less 2-lipped; stamens 4, lower pair rather longer than the upper, which are sometimes abortive.—About 18 species, N. Amer. The oldest generic name of this is *Koellia*, which is used by many, but *Pycnanthemum* is maintained in the list of "nomina conservanda" as accepted by the Vienna Congress. The genus differs from *Monarda* in having smaller and canescent fl.-heads. *Pycnanthemums* are mint-like plants of easy cult. in any good soil. The following grow 1-3 ft. high, and bear fl.-heads ½ in. across or less.

A. *Lvs. lanceolate or linear-lanceolate: calyx-teeth oxate-triangular.*

virginianum, Dur. & Jacks. (*P. lanceolatum*, Pursh). St. rather stout: lvs. fragrant, firm, acuminate at apex, rounded or narrowed at base, 1-2 in. long, 2-5 lines wide. Dry fields, Canada to Ga., west to Minn. B.B. 3:112.

AA. *Lvs. linear: calyx-teeth subulate, bristle-tipped.*

flexuosum, BSP. (*P. linifolium*, Pursh). St. slender: lvs. 1-2 in. long, ½-1½ lines wide. In fields, Mass. to Fla., Ont., Minn., and Texas. B.B. 3:111.

P. Monardella, Michx., is properly *Monarda clinopodia*, Linn. A perennial herb with slender, usually simple st. 1-3 ft. high: lvs. lanceolate to ovate, membranaceous, bright green, slender-petioled, 2-4 in. long: fl.-heads solitary, terminal; corolla yellowish, 1 in. long or less. June-Aug. Fields, Ont. to Ga. B.B. 3:102.

F. W. BARCLAY.

F. TRACY HUBBARD.†

PYCNOSTACHYS (Greek, *thick spike*, referring to the heavy spikes of fls.). *Labiātæ*. Erect perennial herbs: lvs. opposite, broad or narrow, sessile or petioled: whorls condensed into a dense terminal spike; fls. bright blue or violet; calyx slightly accrescent, 5-toothed; corolla-tube longer than the calyx, upper lip short, 4-toothed, lower longer, deeply concave; stamens 4: nutlets subglobose, smooth.—About 40 species, natives of Trop. and S. Afr., 1 in Madagascar. *P. urticifolia*, Hook. A much-branched perennial herb, 5-7 ft. high: lvs. ovate-acute, deeply cut, crenate, densely pubescent: spikes very dense, 2-3 in. long; corolla bright blue. Trop. and S. Afr. B.M. 5365. More or less frequent in gardens in England. *P. Dawei*, N.E. Br. A stout herb, 4-6 ft. high and loosely branched pyramidal habit: lvs. narrowly lanceolate, acuminate, serrate: fls. many, crowded, in short spikes

terminating all the branches, cobalt-blue; calyx-teeth needle-like. Trop. Afr. Intro. into England. B.M. 8450. *P. cærulea*, Hook., with 4-sided st. about 1 ft. high, bright blue fls. and sessile oblong or linear-lanceolate lvs., a native of Madagascar, has also been cult. in England.

PYRACANTHA (Greek, *pyr*, fire, and *akanthos*, thorn; alluding to the bright red fruits). *Rosaceæ*. FIRETHORN. Ornamental shrubs, grown chiefly for their bright red berry-like fruits and also for their white flowers and firm foliage.

Thorny half-evergreen shrubs: lvs. alternate, short-petioled, narrow, crenulate or sometimes entire, stipulate: fls. in corymbs; sepals short, petals suborbicular, spreading; stamens 20, with yellow anthers; carpels 5, free on their ventral side, on their dorsal side connate with the calyx-tube about half or less: fr. a small pome with persistent calyx, red or orange, with 5 stones.—

3264. *Pyracantha coccinea*. (×½)

Three species, from S. E. Eu. to Cent. China and the Himalayas. The genus is closely allied to *Cotoneaster* but is easily distinguished by the crenulate lvs. and the thorny branches, also by the more conspicuous stipules. From *Crataegus* it is chiefly distinguished by the

structure of the ovary, which contains 2 equal ovules in each cell, while in *Crataegus* each cell contains only 1 fertile ovule and a second imperfect and smaller one.

The pyracanthas are usually small shrubs with rather small and narrow leaves and with white flowers in small corymbs followed by bright red or orange fruits. *P. coccinea* is hardy as far north as Massachusetts in sheltered positions. It is a handsome low evergreen shrub, especially when loaded with its bright red fruits, these remaining on the branches all winter if not eaten by birds, which are fond of them; it is also pretty in spring with its numerous corymbs of white flowers. It is well adapted for planting on rocky slopes or sunny rockeries or for borders of shrubberies; it may also be used for low ornamental hedges or for covering walls, as it stands pruning well and is easily trained into any desired shape. It thrives in almost any kind of well-drained soil, including limestone, and prefers sunny positions. Propagation by seeds or by cuttings of ripened wood in fall under glass, kept during the winter in a temperate greenhouse; also by layers and sometimes by grafting on hawthorn or cotoneaster.

A. *Lvs. beneath and calyx glabrous.*

coccinea, Roem. (*Cotoneaster Pyracantha*, Spach. *Crataegus Pyracantha*, Borkh. *Mespilus Pyracantha*, Linn.). FIRETHORN. FIERY THORN. EVERLASTING THORN. Fig. 3264. Shrub, attaining 6 ft., rarely 20 ft., with numerous short spines: young branchlets and petioles grayish pubescent: lvs. oval-oblong to oblanceolate, acute, crenate, glabrous or slightly pubescent when young, ¾-1¾ in. long: corymbs pubescent, many-fl., about 1½ in. broad; fls. small, white: fr. numerous, bright red, about ½ in. across. May, June. Italy to W. Asia. Gn. 33, p. 464. Var. *Lalandii*, Dipp. (*Cotoneaster crenulata*, Hort., not Wenzig), is of more vigorous growth, with slender branches: lvs. less deeply crenate: corymbs larger: fr. bright orange-red. Well suited for covering walls and said to be hardier than

the type. M.D.G. 1901:136. Var. *pauciflora*, Dipp. Of low, dense habit and very thorny: corymbs small: fr. yellowish red. Hardy, and well suited for hedges. Var. *leucocarpa*, Hort. (*Cotoneaster Pyracantha leucocarpa*, Hort., var. *fructo-albo*. Hort.), is a form with white or yellowish frs.

crenulata, Roem. (*Cotoneaster crenulata*, Wenzig. *Crataegus crenulata*, Roxbg. *P. Rogersiana*, Hort.). Closely allied to the preceding: branchlets and petioles rusty-pubescent, glabrous at length: lvs. narrower, oblong to oblanceolate, obtuse or acutish, more leathery, bright green and glossy above, 1–2 in. long: corymbs glabrous: fr. slender-pedicelled, globose, bright orange-red. May, June. Himalayas. B.R. 30:52. R.H. 1913: 204 and p. 205. G.M. 58:31. G.C. III. 57, suppl. Feb. 20.—More tender than the preceding, with handsomer, glossier foliage. Var. *yunnanensis*, Vilm. More vigorous: spines to 2 in. long: lvs. 2–3 in. long, finely denticulate, obtuse: corymbs more numerous, many-flid.: fr. short-pedicelled, bright coral-red, smaller. Yunnan. R.H. 1913:204.

AA. Lvs. beneath and calyx tomentose.

angustifolia, Schneid. (*Cotoneaster angustifolia*, Franch.). Shrub with long and slender, spreading and often partly prostrate branches; young branchlets yellowish tomentose: lvs. subcoriaceous, narrow-oblong, obtuse and mucronulate, recurved at the margin, entire or sparingly glandular-serrulate, glabrous, grayish tomentose beneath, $\frac{3}{4}$ – $2\frac{1}{4}$ in. long: corymbs few-flid., short-stalked; calyx grayish pubescent outside: fr. depressed-globose, $\frac{1}{2}$ in. thick, orange-yellow. May, June. S. W. China. B.M. 8345. G.C. III. 36:441. Gn. 67:105, p. 24.

ALFRED REHDER.

PYRENACANTHA (Greek, *grain, thorn*; the inner surface of the husk of the fruit is covered with many blunt prickles). *Icacinaceae*. Climbing shrubs with alternate, hairy, 3–5-nerved, entire, or toothed or lobed lvs. and fls. in spikes: fls. dioecious; perianth 4- or rarely 3–5-lobed; ovary superior, 1-celled, 2-ovuled: drupe compressed, with the mesocarp spinulose-verrucose within. About 15 species from Trop. and S. Afr. *P. malvifolia*, Engl. A succulent plant with a fleshy subglobose smooth st. resembling a stone from a distance: branches short or long and scandent: lvs. kidney-shaped, irregularly 3–5-lobed, pilose: fls. small, in spikes; perianth 4-lobed. E. Afr. G.W. 10, p. 354.

PYRÆTHRUM (a name used from the time of Dioscorides, the derivation from the Greek, *much fire*, referring to the acid roots). *Compositae*. This name is still commonly used in garden literature and language although the genus has long been reduced to a section of *Chrysanthemum*. Almost every nursery catalogue offers *P. roseum* and its numerous varieties, which is referred by botanists to *Chrysanthemum coccineum*; also *P. parthenifolium* var. *aureum*, the golden feather, and *P. uliginosum*. (See Vol. II, p. 753.) All three of these are rather common in gardens and they are known to most lovers of hardy perennials.

More recent introductions under the name *Pyrethrum* are *P. Tchihatchewii*, also spelled *Tchihatcheffii*, the "turfing daisy" (see *Chrysanthemum Tchihatchewii*, Vol. II, p. 756), and *P. leucopiloides*, Hausskn., a subalpine perennial with silvery white leaves and large yellow flower-heads. Asia Minor. Suitable for the rockery. This last species is not mentioned under *Chrysanthemum*.

PÝROLA (a diminutive of *Pyrus*, the pear tree, from some fancied resemblance in the foliage). *Pyrolaceae*. WINTERGREEN. SHIN LEAF. Low and smooth perennial herbs with running subterranean shoots; suitable for the native garden though not commonly cultivated.

Acaulescent or caulescent, with a cluster of roundish

or elliptical evergreen basal lvs. and a simple raceme of nodding white, greenish or purplish fls. on an upright more or less scaly-bracted scape: calyx 5-parted, persistent; petals 5, concave, deciduous; stamens 10: caps. depressed-globose, 5-lobed, 5-valved.—Ten to 15 species, Great Britain to N. Asia and N. Amer. south to Mex. Formerly referred to *Ericaceae*, but now placed in *Pyrolaceae* together with *Chimaphila* and *Moneses*. The name wintergreen is usually applied to *Gaultheria*.

Pyrolas grow naturally in rather poor sandy uplands and in bogs. Like many members of the heath family, wintergreens are difficult to cultivate and will not succeed in garden soil. In removing them from the woods, care should be taken to secure a large ball of earth. They may then succeed in the shade of evergreens and upon rockeries in peaty soil. The species are scarcely in general cult.; they are offered by dealers in native plants. *P. americana* is probably more cultivated than the others.

A. Fls. greenish; style straight.

secúnda, Linn. Height about 6 in.: subcaulescent: lvs. thin, ovate, crenate, 1– $1\frac{1}{2}$ in. long: fls. small, in a 1-sided, dense, spike-like raceme. N. Atlantic States to Lab., Rocky Mts. to arctic regions, N. Eu. to Japan. June–Aug.

AA. Fls. greenish white; style curved downward.

chlorántha, Swartz. Height 5–10 in.: lvs. small, orbicular, thick, dull, shorter than the petiole: fls. few; anther-cells with beaked tips. Lab. to Pa., Rocky Mts., north to subarctic regions. June and July.

ellíptica, Nutt. Height 8–10 in.: lvs. broadly oval or oblong, thin, dull, serrulate, 2– $2\frac{1}{2}$ in. long, longer than the petiole: loosely 5–10-flid.; calyx-lobes ovate, acute, one-fourth length of the obovate whitish petals. Canada to Brit. Col. and through N. Atlantic States to New Mex., Japan. June and July.

pícta, Smith. Height 5–10 in.: lvs. thick, broadly ovate to spatulate, dull, blotched with white above, pale or purplish beneath, longer than the petioles: calyx-lobes ovate, not one-half length of the greenish white petals. Pacific slope.

AAA. Fls. white.

americána, Sweet (*P. rotundifolia*, Amer. Auth., not Linn.). Height 5–12 in.: lvs. orbicular, about 2 in. long, thick, shining above, shorter than the petioles: fls. numerous; bracts conspicuous; calyx-lobes lanceolate or oblong-lanceolate, one-third to one-half length of the thick white petals. E. Canada, south to Ga., west to S. D. June–Aug.

AAAA. Fls. pink or purple.

asarifolia, Michx. Lvs. transversely broad-elliptic or round-reniform, cordate: fls. $\frac{3}{8}$ – $\frac{5}{8}$ in. across, purple; calyx-lobes ovate to ovate-triangular. Que. to Yukon, south to Nova Scotia, N. New England, W. N. Y., N. Mich., and Col.; also in Asia. June–Aug.

Var. *incarnáta*, Fern. (*P. rotundifolia* var. *uliginosa*, Gray), with pink or rose-colored fls. and subcordate to obovate, dull lvs., occurs in swamps, arctic regions, south to N. New England, Cent. N. Y., Mich., Wis., Col., and Calif.; also Asia. F. TRACY HUBBARD.†

PYROLÍRION: *Zephyranthes*.

PYROSTÈGIA (Greek, *pyr*, fire, and *stega*, roof; alluding to the color of the flowers and the shape of its upper lip). *Bignoniaceae*. Ornamental vines cultivated chiefly for their handsome and showy flowers.

Evergreen shrubs climbing by tendrils: lvs. 2- or 3-foliolate; tendrils filiform, 3-parted: fls. in terminal panicles; calyx campanulate or nearly tubular, truncate or dentate; corolla tubular-funneliform, curved, the lobes valvate in bud; stamens exceeding the tube; disk annu-

lar or slightly cupulate; ovary linear with the seeds arranged in 2 rows or in zigzag; pod linear with leathery valves and elliptic winged seeds.—Four species in S. Amer. Formerly usually united with *Bignonia*, but easily distinguished by the lobes of the corolla being valvate in bud and by its tubular, nearly claviform shape. Cult. and prop. like *bignonia*.

venusta, Baill. (*P. ignea*, Presl. *Bignonia venusta*, Ker). Fig. 3265. Sts. striate or somewhat angled, pubescent while young; lfts. usually 3, ovate to ovate-oblong, shortly and obtusely acuminate, cuneate at the base, glabrous above, puberulous beneath, $1\frac{3}{4}$ – $2\frac{1}{4}$ in. long; fls. in drooping panicles; calyx campanulate, shortly 5-toothed; corolla tubular-funnelform, crimson-orange, 2–3 in. long, with oblong, obtuse, reflexing lobes. Brazil. B.M. 2050. P.M. 7:123. B.R. 249. G.C. II. 11:274. A.F. II:1023. J.H. III. 49:281. G. 5:481. H.U. 5, p. 1.—One of the best rafter plants for warm greenhouses; blooms profusely in early winter.

ALFRED REHDER.

PYRULÀRIA (diminutive of *Pyrus*; alluding to the shape of the fr.). *Santalaceæ*. OIL-NUT. BUFFALO-NUT. A shrub in E. N. Amer. and 2 trees in the Himalayas with alternate, deciduous, entire lvs. and greenish fls. in spikes or racemes; fls. subdiceious, apetalous;

3265. *Pyrostegia venusta*. ($\times \frac{1}{2}$)

sepals and stamens 4–5; filaments short; ovary inferior, 1-celled, with 2–3 ovules; fr. a 1-seeded drupe. The species in cult. is *P. pubera*, Michx. (*P. oleifera*, Gray). A straggling shrub, to 12 ft., puberulous while young; lvs. short-petioled, obovate-oblong, acute or acuminate, cuneate at the base, minutely punctulate, 2–6 in. long; spikes terminal, few-fl.; calyx 5-cleft; fr. pear-shaped or subglobose, yellowish, about 1 in. long, crowned by the ovate calyx-lobes, containing an acrid oil like the whole plant. May. Pa. to Ga. and Ala. B.B. (ed. 2) 1:641.—Of no particular ornamental value, but botanically interesting; half-parasitic on the roots of *Tsuga* like *Buckleya*, which see for cult. ALFRED REHDER.

PYRUS (Latin name of pear tree). Sometimes spelled *Pirus*. *Rosaceæ*. THE POME-FRUIT, as all the kinds of pears, apples, and crab-apples; also many small trees and bushes grown for the very handsome early flowers and sometimes for the attractive habit, foliage, and little fruits.

Woody plants, bearing mostly on spurs, with simple but sometimes lobed alternate lvs. (pinnatifid sometimes in *P. heterophylla*); fls. usually perfect, but rarely polygamous, regular, in spring; torus urn-shaped and attached to the carpels and finally closing over them,

and with them becoming fleshy in fr.; calyx-lobes 5 and persistent upon the top of the young fr., or in some cases falling away at maturity or before; petals 5, white or red, perigynous; stamens 15–20 or more; styles 2–5, crowning a 2–5-loculed inferior ovary in which the locules are usually 2-seeded. (Figs. 3266,

3266. Flowers of apple. The ovaries are shown in the section, an ovule being at O.

3267). *Pyrus* is a polymorphous genus, in the northern hemisphere. The species are mostly small trees, bearing clusters of showy white or bluish fls. with the lvs. or in advance of them. They are natives mostly of cool temperate regions, and the greater part of them are hardy in the northern United States. There are widely unlike practices among botanists in defining this important and interesting genus. Half a century ago, when it was a widely prevalent practice to assemble groups which agree in general gross structure and which can be held together by a broad definition, *Pyrus* was held to include not only the pears and apples, but the mountain-ashes or sorbus, the medlar and quinces, the chokeberries and other groups (Bentham & Hooker, *Genera Plantarum*, 1867). As late as 1894, Focke (Engler & Prantl, *Pflanzenfamilien*) holds *Pyrus* intact except for the separation of *Cydonia* and *Mespilus*. While many botanists still hold most or all of these groups in *Pyrus*, the present tendency to segregate all groups for which separate definitions can be found results in the dismemberment of *Pyrus*. As the old rather gross assemblage, resulting from the effort to find agreements, can hardly be expected to hold, so the present disunion, resulting from the effort to find differences, may be expected to pass, and the practicable and convenient grouping may be found somewhere between the two extremes. There seems to be good justification for the separation of *Cydonia* and *Mespilus*, and perhaps also for *Sorbus* and *Aronia*, but it is yet to be determined whether the separation of *Malus* (the apples) will meet with continuing favor. See *Malus*, p. 1973, Vol. IV. The many-seeded carpels of *Chaenomeles* (Figs. 3268, 3269) and *Cydonia*

3267. Longitudinal section of flower of *Pyrus Halliana*.

3268. Lengthwise section of *Chaenomeles Maulei*, by some referred to *Pyrus*, to show many-seeded carpels and the lack of peduncle.

3269. Lengthwise section of *Chaenomeles cathayensis*.

and the absence of fr.-stalk (Fig. 3270) afford good structural characters, as well as the fl.-bearing habit and other characters. Many of the species that have been named under *Pyrus* will be found in *Sorbus*.

If the genus is held to comprise the pears and apples and no others (*Pyrophorum* and *Malus*), there are probably fifty or sixty species.

The aronias, by some kept as a distinct genus (page 396, Vol. I.), comprise a small group of North American bushes with white flowers in corymbs and attractive little fruits.

Under *Pyrus*, the names are *P. arbutifolia*, Linn., the red chokeberry; *P. atropurpurea*, Bailey, the purple chokeberry, sometimes regarded as a variety of the former; *P. melanocarpa*, Willd., the black chokeberry; *P. floribunda*, Lindl. (not Hort.), of garden origin.

The fruit of *Pyrus* is of the kind known to botanists as a pome. The morphology of the pome is still perhaps a subject of disagreement, although most botanists now consider it to be a hollow torus (receptacle), or hypanthium, or cupula, in which the ovary is imbedded. Fig. 3271 illustrates the theoretical structure. The ovary is at *b*, wholly inclosed in the fleshy torus *a*. Most of the edible part of the apple or pear, therefore, is considered to be torus, whereas the core is ovary. This ovary, in common apples and pears, is of five carpels or cells, as shown in the cross-section (Fig. 3272). It was formerly held that the edible part is largely calyx-tube, but various morphological considerations have inclined students to regard it as stem rather than calyx; the term calyx-tube is still retained, however, in descriptive writings. One of these considerations is the fact that apples sometimes bear a rudimentary leaf (as in Fig. 3273), an organ which is commonly borne only by stems.

Apples sometimes take on most unusual and grotesque shapes, and two or more fruits may coalesce into one. Some of these forms, from an orchard of Pearmains, are shown in Fig. 3274. These malformations may be due in part to insufficient pollination, although such teratologies are yet to be well explained.

Aside from the pomological pears and apples, the genus *Pyrus* as here defined includes many very attractive small trees and shrubs. The outlying pear species are not much grown, although well worth cultivation for

interesting foliage and for good white spring bloom. *P. salicifolia*, *P. elaeagnifolia*, and *P. betulæfolia* are among the best of these, and the only ones that are likely to appear in collections. The silvery foliage of the first two is attractive. They are hardy in the northern states and probably in Ontario.

It is among the crab-apples, however, particularly of

the Asiatic species, that the most ornamental plants are to be found. Some of them, as *P. pulcherrima* (*P. floribunda*) and *P. Halliana*, have long been popular, but several others are fully as good and it is possible to secure considerable variety. All the species included in the numbers 21 to 36 in this account are probably hardy in parts of New York state and some of them can be grown in Canada. *P. baccata* is hardier even than the common apple tree, and is therefore sometimes used for stocks and as a parent in hybridizing. All these crabs may be raised as seedlings, for they bloom profusely when only a few years old, or they may be grafted on any of the related stocks. The Asiatic crabs are profuse bloomers, and the pink-and-white effect of blossoms and buds as the leaves are unfolding or just preceding the leafage constitutes one of the most charming prospects in the spring plantation. Some of them hold their small berry-like fruits well into the winter, or even to spring, affording a continuing interest. They are of the easiest culture in well-drained soil. All the species are probably subject to scale, and they should be well sprayed. Particularly to be recommended for the central and northern states east of the Great Lakes are *P. pulcherrima*, *P. Halliana*, *P. Scheideckeri*, *P. Sieboldii*, *P. prunifolia* var. *Rinki*, and *P. Sargentii*, the last a bush with pure white flowers.

The native American crabs, described in numbers 37 to 45 in this list, are yet little known to planters, but they comprise much promising material, and they should yield horticultural subjects for the entire area of the United States, outside the semi-tropical regions, and for good parts of Canada. As a class they bloom later than the Asiatic species. As yet, only *P. ioensis* appears to have yielded a good double-flowered form. With the recent botanical discrimination in this interesting group, attention will probably be called to a closer study of the forms by collectors. They are easy of culture, and may be readily increased by grafting.

Hybridizing will probably play an important part in the horticultural development of the ornamental crabs, as they cross freely. It is probably due to this cause that the Asiatic forms are so difficult to distinguish botanically. The pears and apples appear not to intercross, although the curious *P. auricularis* is generally considered to be a hybrid between the pear and the beam-tree (*Sorbus Aria*).

The pear may be made to grow for a time when grafted on the apple, but it is usually impossible to graft the pear species permanently on the apple species with any degree of success; yet pears thrive on quinces and also on hawthorns, which are well-marked genera. In nursery practice when pear stocks are not at hand, long pear cions may be worked on apple pieces and roots may form from the cion and the pear become own-rooted on the failure of the apple stock. Apples appear not to be successful on pears.

THE TWO GROUPS.

1. PEARS (*Pyrophorum*).—Fr. either with a conical base or possessing a cavity like an apple, the flesh bearing grit-cells (unless ripened off the tree); styles usually free or not united at the base: calyx-tube or hypanthium closed by a cushion-like formation, in fl.; fls. white. Species 1-18. Of these plants there are perhaps 15-20 species, native to S.-Cent. Eu. through the Grecian-Asia-Minor-Syrian region to China. There are no representatives indigenous, so far as known, in N. Amer. or Japan.

2. APPLES (*Malus*).—Fr. usually with a distinct depression at either end, the flesh without grit-cells; styles more or less united below: calyx-tube or hypanthium open; fls. pinkish, rose-color or light red, sometimes clear white. Species 20-45. There are probably 40 good species of this subgenus, of wide distribution. The common apple, *P. Malus*, is probably indigenous in S. W. Asia. In

Siberia, China, and Japan, several species are native, of which the best known are the smooth-growing crab trees with small frs. that shed their calices. In N. Amer. is another set, represented by the Garland crab, *P. coronaria*, the Prairie States crab, *P. ioensis*, and the far western crab, *P. fusca*. The American forms have recently been re-defined into several species, the actual limitations of which

3275. *Pyrus communis*. ($\times \frac{1}{2}$)

are yet to be determined. It has been difficult to find good characters to separate the small-fruited apples, particularly the Asiatic forms. Carrière attempted to solve the difficulty (*Pommiers microcarpes*, Paris, 1883) by referring them all to one polymorphous species-group, *Malus microcarpa*. The recent study of the Asiatic material, however, has resolved it into a number of well-marked species-forms.

I. PYROPHORUM, or PYRUS proper. The Pears.

A. The occidental or Eurasian pears, being the common pomological pears of this country: lvs. appressed- or crenate-serrate or entire (at least not setose-serrate), mostly abruptly pointed: calyx usually persistent at apex of fr.

1. *communis*, Linn. COMMON PEAR. Figs. 3275; also Figs. 2805 and others, p. 2505 and following. Strong upright tree, living to a great age and sometimes attaining a height of 75 ft. and a girth of 15 ft. and more, the lvs. on short spurs as well as on the axial growths, the pedicels and sometimes the young growth pubescent, but all parts becoming glabrous: lvs. mostly oblong-ovate, with a prominent point, hard in texture and veiny, bright green, the serratures small and much appressed and obtuse, or sometimes the lf. is almost entire: fls. 4-12 in umbel-like clusters on slender (2-3-in.) pedicels, white, appearing with the lvs.; calyx persistent, or rarely deciduous; stamens 15-20: fr. very various under cult., usually tapering to the st., the flesh generally with gritty concretions. Native to S. Eu. and Asia, where it has been cult. from the earliest times.—Probably indigenous as far east as Kashmir. In the Syrio-Persian region are several very distinct pyruces of the pear group, a number of which may be outlying forms of *P. communis*. In the wild in Eu., various thorny and small-fruited forms are known.

Var. *Pyraster*, Linn. Much like the type of *P. communis*, but the fr. globose: lvs. more rounded, strongly serrate, glabrous when young: usually thorny. Probably a wilding form.

Var. *sativa*, DC. The cult. pear, in many pomological forms, the tree large and free-growing and without thorns: lvs. large.

Var. *cordata*, Hook. f. (*P. cordata*, Desv.). A spiny shrub, wild in England and France: lvs. smaller than in the type (about 1 in. broad), ovate or nearly orbicu-

3274. Undeveloped, misshapen and coalesced apples, all from one orchard of Pearmain.

lar, subcordate; fls. smaller; fr. globose to slightly turbinate, about $\frac{1}{2}$ in. diam.; calyx persistent.

There are garden forms of *P. communis*, differing in foliage, as var. *trilobata*, Hort., lvs. lobed; var. *heterophylla*, Hort., lvs. cut; var. *variegata*, Hort., lvs. variegated. In Algeria is var. *longipes*, Henry (*P. longipes*, Coss. & Dur.), a small tree with few spines: lvs. with long slender petiole, ovate, acuminate, subcordate, about 2 in. long and 1 in. broad; fr. globose, about $\frac{1}{2}$ in. diam., the calyx deciduous. In Spain is var. *mariana*, Willk., a small tree, with ovate lvs. about 1 in. long, rounded at base, on very long slender petiole; fr. globose, about $\frac{1}{2}$ in. diam., the calyx persistent.

2. *nivalis*, Jacq. SNOW PEAR. Tree, without thorns, the shoots grayish pubescent; lvs. 2-3 in. long, elliptic to oval to obovate-oval, obtuse or short-acute, cuneate at base, entire or toward apex minutely crenulate, gray-pubescent; fls. large, white, showy; fr. small, roundish pyriform, late-ripening, acid, becoming sweet when overripe. Austria, and wild in France and elsewhere, but probably as an escape.—The snow pear is a small tree, with thick shoots that are white- or gray-hairy when young. It is grown in parts of Eu., particularly in France, for the making of perry or pear cider, the greater part of such varieties being of this species. By some writers it is considered to be a form of *P.*

3276. *Pyrus serotina*. ($\times \frac{1}{2}$)

3277. *Pyrus ussuriensis*. ($\times \frac{1}{2}$)

communis, and by others to be a hybrid race of *P. communis* and *P. amygdaliformis*; Schneider, however, places it as a good species with which he associates other names as synonyms and varieties, and according to his view *P. salicifolia*, DC. (sage-lvd. pear of the French), is *P. nivalis* $\times$ *P. communis*. It is not known to be in cult. in this country, but it is to be looked for in arboreta and other collections. Said to be called "snow pear" because the frs. are fit for eating after snow falls.

The following related species may be expected to appear now and then in trade-lists or in special collections:

3. *P. amygdaliformis*, Vill. (*P. parviflora*, Desf. *P. cuneifolia*, Guss. Probably *P. sibirica*, Dum.). Shrub or small tree (to 30 ft.), spiny, with lightly tomentose buds and young branches; lvs. thick and coriaceous, 1-2 in. long, narrow-elliptic, oblong-lanceolate or oblong-oblancheolate, at apex short-acuminate or rounded-mucronate, mostly narrowed or cuneate at base, tomentose when young but becoming nearly or completely glabrous, the petiole short or slender and mostly glabrous, the margin entire or on large lvs. serrulate; fr. nearly globular, $\frac{3}{4}$ in. diam., green and hard. France to Asia Minor, in mountainous places. B.R. 1484 (as *P. nivalis*). G.W. 14, p. 286.—The names *P. Michauxii*, Bosc., *P. persica*, Pers., and *P. oblongifolia*, Spach, probably represent hybrids of this species with *P. nivalis*.

4. *P. auriculäris*, Knoop (*P. irregularis*, Muenchh. *P. Pollveria*, Linn. *P. Bollwyleriana*, DC. *Sorboipyrus auriculäris*, Schneid.). Regarded as a hybrid of *P. communis* and *Sorbus Aria*;

was discovered about 1650 at Bollweiler, in Alsace: it bears very sparingly, and apparently does not come true to seed: to 50 ft., with buds and branchlets tomentose; lvs. 3-4 in. long, elliptic, unequal and rounded at base, short-acuminate, irregularly and coarsely sharp-serrate or double-serrate, lower surface pubescent; fls. 5 or more in tomentose clusters, on slender pedicels; calyx-tube and lobes tomentose; styles 2-5; fr. 1 in. diam., pyriform, reddish yellow, sweet. Now and then planted in botanic gardens and elsewhere. B.R. 1437. L.B.C. 11:1009.—*P. malifolia*, Hort. (and Spach?) is probably a hybrid of similar or related origin.

5. *P. elaeagnifolia*, Pall. (*P. nivalis* var. *elaeagnifolia*, Schneid.). Small spiny tree, the young shoots tomentose; lvs. lanceolate to oblong or obovate-lanceolate, entire, usually silky-tomentose, the base mostly tapering and the apex obtuse-mucronate or short-acuminate; fls. small, on densely tomentose pedicels; fr. globose-turbinate, glabrous, the calyx persistent. Caucasus, S. Russia. The specific name was first written, by Pallas, *elaeagnifolia* (not *elaeagnifolia*), because he considered *elaeagnus* to be the proper spelling of the name of the oleaster genus, it having been spelled that way by Dioscorides. Var. *Kotschyana*, Boiss. (*P. Kotschyana*, Boiss. *P. nivalis* var. *Kotschyana*, Schneid.), is usually spineless, the lvs. larger (3 in. long), the fr. globose and larger (about 1 in. diam.).

6. *P. heterophylla*, Regel & Schmalh. Small thorny glabrous tree, with very variable foliage, some plants having lvs. that are entire at the margin, others are slit and almost of thread-like form, but the greater number with forms intermediate between these two extremes, usually ovate in outline, but mostly pinnatifid and the segms. again toothed; fr. nearly globose with the ends somewhat flattened, about 1 in. diam. Turkestan. G.C. III. 7:115.

7. *P. Korshinskiyi*, Litw. Tree, to 20 ft. or more, or a shrub, with branchlets and buds gray-tomentose; lvs. coriaceous, about 3 in. long, lanceolate or ovate-oblong, somewhat tomentose above and beneath, the margins with coarse crenate or double-crenate incurved gland-tipped serratures, the petiole long and tomentose; fr. nearly globose, stout-peduncled, nearly 1 in. diam., with persistent calyx. Bokhara, Turkestan.

8. *P. salicifolia*, Pall. Small tree, often spiny, becoming 30 ft. tall, with gray-tomentose branchlets; lvs. willow-like, 2-3 in. long, (whence the name), linear-lanceolate or lanceolate, mostly tapering toward both ends, entire or very nearly so, hoary beneath; fls. white, in corymbs, short-pedicelled; fr. round-pyriform, short stemmed, yellow or greenish, about $\frac{3}{4}$ in. diam., the calyx persistent. Caucasus, Armenia. G.C. II. 14:145. G. 34:305.—A showy spring-flowering small tree, hardy in the northern states, and worthy of being better known. Var. *pendula*, Hort., has drooping branches. G. 22:649. *P. canescens*, Spach, is perhaps a form or hybrid of *P. salicifolia*; lvs. lanceolate or narrow-elliptic, about $2\frac{1}{2}$ in. long, at apex acute or mucronate, minutely crenulate, sometimes twisted, tomentose.

AA. The oriental or Chino-Japanese pears, grown in this country to some extent for ornament and fr., and producing hybrids with *P. communis*: lvs. mostly markedly acuminate and very sharp-serrate or setose-serrate; calyx usually falling from the apex of the fr. in the cult. forms (not so in *P. ussuriensis* and *P. ovoidea*). (See Rehder, Synopsis of the Chinese Species of *Pyrus*, Proc. Amer. Acad. Arts and Sci. 50:225-40; also *Plantae Wilsonianae*, 2:263-6.)

9. *serotina*, Rehd. Fig. 3276. Tree, 20-50 ft., the branchlets glabrous or becoming so; lvs. ovate-oblong or seldom ovate, 3-5 in. long, rounded at base and rarely subcordate or cuneate, long-acuminate, strongly and sharply setose-serrate, with partially appressed serratures, when young villous or beneath cobwebby but becoming glabrous; infl. umbellate-racemose, 6-9-flid., glabrous or somewhat tomentose, the pedicels slender; fls. white; sepals or

3278. *Pyrus ovoidea*. ($\times \frac{1}{2}$)

3279. *Pyrus Lindleyi* ($\times \frac{1}{2}$)

XCIV. The bloom of *Pyrus pulcherrima* (*P. floribunda*).

calyx-lobes triangular-ovate and long-acuminate, $\frac{1}{4}$ to about $\frac{1}{2}$ in. long, glandulose-denticulate; petals oval, short-clawed, nearly $\frac{3}{4}$ in. long; stamens about 20; styles 4 or 5, glabrous; fr. subglobose, brown, slender-stalked, the calyx deciduous. Cent. and W. China. B.M. 8226 represents a form named by Rehder var. *Stapfiana*, differing in pyriform fr., less appressed serratures on the lvs., and petals attenuate-clawed.

P. serotina or its forms is recommended on the Pacific Coast as a more or less blight-resistant stock for the European types.

Var. *culta*, Rehder. (*P. sinensis*, Hort., not Lindl. nor Poir. *P. sinensis* var. *culta*, Makino). SAND PEAR. Fig. 2808, p. 2507, the details of lf.-margins not showing. JAPANESE and CHINESE PEAR of pomologists. Differs from the type of the species in its large pyriform or apple-form fr., larger and broader lvs. (which are often 6 in. long and 3-4 in. broad). Japan.—A very rapid-growing tree, with strong, thick shoots: lvs. broadly ovate and

long-pointed, very dark green, the margins thickly furnished with very sharp, sometimes almost bristle-like teeth: fls. large, appearing rather in advance of the foliage: fr. hard and usually roughish, commonly with a depression or "cavity" about the st., the flesh tough and gritty and poor in flavor, the calyx usually falling before maturity. R.H. 1879:170; 1880:110 (as *P. Sieboldii*).—Known in this country in a number of varieties, as Chinese Sand, Japanese Sand, Hawaii, Madame von Siebold (which pomological variety Rehder writes, "may be considered as representing the type" of var. *culta*), Mikado, Diamyo, Gold Dust. The frs. are often remarkably apple-like, especially in the russet varieties, but they are distinguished by the long st. and pear-like flesh. The Japanese pear is little prized for its fr. although the pears are useful for preserving and some of the varieties are showy and the frs. are good keepers; it is used for stocks upon which to work the common pear, and it has given good results in hybridizing. It is an excellent ornamental tree, being a clean grower of great vigor. Kieffer, Le Conte, and others are hybrids of *P. communis* and *P. serotina* var. *culta* (Figs. 2809-2810). This type has a stronger growth than the common pears, the lvs. are usually broader and darker green, with closely and mostly obtusely serrate edges, the fr. is more or less pyriform and of better flavor than that of the oriental parent, and the calyx is either persistent or deciduous. Seedlings of Kieffer often produce the sharply toothed lvs. of *P. serotina* var. *culta*.

Other oriental pears are likely to appear in cult., and it is necessary to distinguish them briefly.

A. Calyx persistent: fr. yellow.

B. Lvs. setosely and sharply serrate.

C. Fr. globose or subglobose, short-stalked: lvs. orbicular-ovate or ovate, these and infl. glabrous from the first.

10. *P. ussuriensis*, Maxim. Fig. 3277. Differs from its allies, according to Rehder, chiefly in the short stalk of the fr. which is globose and has a persistent calyx, in the broad often nearly orbicular strongly setose-serrate lvs., and in the lighter yellowish brown color of the branchlets; fl.-clusters rather dense and hemispherical, owing to the short stalks: petals obovate and rather gradually narrowed toward base; styles distinctly pilose near the base. Manchuria, Amoorland, N. China. R.H. 1872, p. 28 (as *P. Simonii*, Carr.).—Sometimes spiny; branches often yellow-gray.

CC. Fr. ovoid, long-stalked: lvs. oblong-ovate or ovate, these and the infl. at first more or less floccose-tomentose.

11. *P. ovoidea*, Rehder. Fig. 3278. Differs from *P. ussuriensis* chiefly in the narrower lvs., darker-colored branches, and longer-stalked longer-shaped fr. which has spreading persistent sepals: in longitudinal section the yellow juicy fr. is described as exactly ovate, broad and rounded at the base, tapering from the middle toward a truncate apex, thus constituting a pear of unusual and distinct shape. China.—Blooms a week ahead of other species of pears; the foliage turns bright scarlet in autumn. Hardy N. Sometimes grown as *P. Simonii*.

BB. Lvs. denticulate or serrate but the serratures not setose-acuminate: fr. oval in outline, long-peduncled.

12. *P. Lindleyi*, Rehder. (*P. sinensis*, Lindl., not Poir.). Fig. 3279. Known only from Lindley's descriptions and figure, and perhaps a cult. form of some other species: the lvs. have short and rather small appressed teeth that are not at all acuminate, or those on the short growths nearly crenate-serrate; in shape ovate and abruptly acuminate, rounded at the base and those on the short branchlets mostly subcordate. China. B.R. 1248 (as *P. sinensis*). Lindley's name, *P. sinensis*, has long been used for the sand pears, which plants must now bear the name *P. serotina* var. *culta*.

AA. Calyx falling: fr. yellow or brown.

B. Lvs. setosely serrate: fr. yellow.

13. *P. Bretschneideri*, Rehder. Fig. 3280. Medium-sized tree, closely allied to *P. ovoidea* but distinguished by the deciduous calyx and the ovate or elliptic-ovate-acuminate lvs. which have a broadly cuneate or very rarely a rounded base; lf.-margins sharp-serrate, at first setose-acuminate but serratures becoming only acuminate and somewhat appressed: fr. subglobose or globose-ovoid, about 1 in. long and nearly or quite as thick, the base contracted into a stalk 1-1 $\frac{1}{2}$ in. long, hanging, yellow and marked with pale dots. China.—Supposed to be the species that yields some of edible pears of Peking. Hardy N.

BB. Lvs. sharply serrate or dentate-serrate but the serratures not setose: fr. brown.

C. Styles 2-3: lvs. mostly coarsely dentate-serrate, the base usually broadly cuneate. fr. very small.

14. *P. betulæfolia*, Bunge. Fig. 3281. Tree, to 20 ft., without thorns, the buds and branchlets gray-tomentose, the head rather narrow, the foliage pale and the fls. rather small: lvs. ovate-acuminate or rhombic-ovate-acuminate, cuneate at base, long-stalked, sharp-serrate, becoming shining green above, pale tomentose or glabrous beneath: fls. white, $\frac{3}{8}$ in. across, the styles and cells of ovary 2: fr. nearly globular, size of a pea, brown and dotted, the calyx falling. China. Hardy in New England and Canada. R.H. 1879, pp. 318, 319. G.F. 7:225 (reduced in Fig. 3281). A.F. 13:1396. Eng. 6:309.—A worthy plant for ornament, bearing a profusion of fls. in advance of the lvs. or at the time of the expanding of the lvs. It has been used as a stock for some of the pomological pears. It is subject to pear-blight.

15. *P. Calleryana*, Deene., although Chinese, in lf. resembles the crenate-serrate Eurasian type rather than the sharp-serrate or

3280. *Pyrus Bretschneideri*.
($\times \frac{1}{2}$)

3281. *Pyrus betulæfolia*.
($\times \frac{1}{2}$)

setose-serrate Chino-Japanese type: lvs. ovate, mostly rounded at base, small, crenate, glabrous; fls. small, with only 2 or 3 styles, in a glabrous infl.; stamens about 20; fr. size of a pea, globular but contracted abruptly into a long slender stalk, calyx deciduous.

cc. Styles 3 or 4, sometimes 5: lvs. mostly rounded at base: fr. mostly larger.

D. Lf.-margins strongly serrate, with acute or somewhat appressed serratures.

16. *P. serrulata*, Rehd. Small tree, most closely related to *P. serotina* but distinguished by the not-setulose serratures, shorter lvs., smaller fls. with styles less than 5, triangular-ovate rather than long-acuminate sepals or calyx-lobes, and subglobose or globose-obovoid brown fr. which is less than 1 in. long. China.—*P. hupehensis*, Pampan., from Cent. China, is probably this species or very closely related: described as a tree with straight slender trunk: lvs. more or less ovate, rounded or cuneate at base, long-acuminate, sharp-toothed, cream-colored beneath: fls. in dense clusters.

3282. *Pyrus phaeocarpa*. ($\times \frac{1}{2}$)

narrow-ovate, 2–3½ in. long, glabrous, subcordate at base, long-acuminate at apex: calyx-lobes broad and rounded and the fls. in glabrous corymbs: fr. globose, 1 in. diam., the calyx early deciduous. Kashmir to Kumaon in W. Himalaya and to Yunnan. B.M. 8256.

DD. Lf.-margins dentate-serrate, the serratures erect-spreading.

18. *P. phaeocarpa*, Rehd. Fig. 3282. Medium-sized tree: lvs. elliptic-ovate or oblong-ovate, attenuated into long point, the base mostly broadly cuneate, the serratures at first more or less incurved but becoming open or spreading: fr. pyriform, about 1 in. long, slender-stalked, brown or russet. China. Var. *globosa*, Rehd., has globular fr. and lvs. usually ovate and round-based. The fls. of *P. phaeocarpa* are unusually large, lvs. deep green and very lustrous; a handsome small tree. Hardy N.

lvs., about 5 or 6 in each cyme; sepals or calyx-lobes 5, acuminate; petals 5, obtuse, mostly pink on the outside; stamens about 20, with yellow anthers: fr. very various, with a cavity about the st., a homogeneous flesh and persistent calyx.—Cult. from remote antiquity, and thought to be native to Eu. and W. Temp. Asia to the Himalayas. It has run wild in many parts of Eu. Attempts are made to recognize two or more species in the group of common apples, but the efforts are not

3284. *Pyrus Malus* var. *apetala*. The bloomless apple.

very successful in practice. Some authorities consider that there are two original species and that the common pomological apple represents a welding of them through hybridization.

Var. *sylvestris*, Linn. (*Malus sylvestris*, Mill. *M. acérba*, Mérat. *Pyrus acérba*, DC.). Mostly a wild or run-wild nearly or quite glabrous form, to which not many of the cult. pomological varieties can be referred: young branchlets glabrous or soon becoming so: lvs. glabrous above, shining and only scattered-pubescent beneath, the petiole and pedicels only slightly pubescent: calyx-tube and outside of calyx-lobes glabrous but the latter pubescent inside. W. and Cent. Eu.

Var. *pumila*, Henry (*Malus pumila*, Mill. *Pyrus pumila*, Koch). The pubescent type, the source of nearly all the pomological apples, and kept specifically separate by some writers: small or large tree, or bush-like: young branches prominently tomentose, as well as

3283. *Pyrus Malus*, the apple.

II. MALUS. The Apples.

A. The pomological apple-species, grown for their edible frs. (with ornamental forms).

B. Calyx persistent on the ripe fr.

19. *Malus*, Linn. (*Malus communis*, DC. *Malus Malus*, Brit.). APPLE. Fig. 3283; also under Apple, Vol. I. A round-headed tree or a large bush, with foliage clustered on short shoots or spurs and also borne on the slender axial growths: lvs. oval, ovate or orbicular-ovate, mostly pointed at apex and rounded at base, soft in texture, dull, the margins irregularly serrate, on stout petioles: fls. large and showy, white or light rose, in close clusters on short pedicels, appearing with the

are the pedicels, calyx-tube, and both surfaces of the calyx-lobes: lvs. ovate or oval, dull and more or less tomentose beneath. Thought to be native only in S. E. Eu. and in Asia, although run wild elsewhere. A very dwarf form is the Paradise apple (*P. Malus* var. *paradisiaca*, Linn.), used as a stock on which to dwarf the pomological varieties.

Var. *astracánica*, Loud. (*Malus astracánica*, Dum. *Pyrus astracánica*, DC.). Distinguished by large coarsely serrate or doubly serrate lvs. which are tomen-

tose beneath, and by the long pedicels. Probably Asian.

Var. *Niedzwetzkyana*, Asch. & Graebn. (*Pyrus Niedzwetzkyana*, Hemsl.). Mature lvs. tinged red on midrib and nerves, the fls. deep pink, the flesh of the fr. purplish; wood and bark also red or reddish. S. W. Siberia and Caucasus. B.M. 7975. R.H. 1906:232. F.S.R. 2:344.—A very ornamental tree.

Var. *apétala*, Asch. & Graebn. (*Pyrus apétala*, Muenchh. *P. dioica*, Moench). BLOOMLESS APPLE. Figs. 3284, 3285. Fls. with no colored petals, these organs being represented by very small green bract-like or sepal-like bodies, the sepals appearing, therefore, to be in 2 rows; stamens absent; styles 10–15; ovary 6- or 7-celled, perhaps more: fr. (apparently produced by pollination with other apples) much as in common apples except for a deep not closed cavity at the apex, there being one "core" above the other due probably to the crowding of the many cells as the pistil grows; as the apple grows, some or all the cores split open, and cause the hole in the top of the fr.; in Fig. 3285, *b* and *c* represent the persistent points of ruptured core-walls, and *a* marks a thickened petal or bract that stood in the fl. This monstrosity has been long known, and now and then recurs.

There are horticultural forms of *P. Malus* distinguished as: Var. *aurea*, Hort., with yellow-variegated lvs.; var. *plena*, Hort., with more or less double fls.; var. *péndula*, Hort., of weeping or drooping habit.

3285. *Pyrus Malus* var. *apétala*.—The bloomless apple, in longitudinal section.

20. *Soulardii*, Bailey (*Malus Soulardii*, Brit.). SOULARD CRAB. Figs. 3286, 3287. Apparently natural hybrids of *P. Malus* and *P. ioensis*: a small tree, with much the look of an apple tree, and woolly: lvs. large, round-ovate to elliptic-ovate or oblong-ovate, either rounded or tapering at the base, often very blunt or even rounded at the top, mostly bluntly and coarsely serrate or dentate when young, irregularly crenate-dentate at maturity, with a tendency to become lobed, on short pubescent petioles, thick and often rugose and woolly beneath: fls. bluish, in close woolly clusters like those of the apple: fr. often 2 in. or even more in diam., flattish lengthwise, yellow and often with a tinted cheek, the basin shallow, flesh fairly edible. Wild in the Mississippi Valley from Minn. to Texas, but always local and in different forms of fr.—Named for James G. Soulard, Galena, Ill., who intro. the first variety to cult. In some forms the lvs. become nearly smooth late in the season and there is little tendency toward an irregular notching or lobing of the margins. The tree is hardy and the fr. keeps well and is useful for culinary purposes. A few named varieties are grown in the upper Mississippi Valley, where trees of great hardiness are demanded. For accounts of the pomological offshoots of our native apples, see Bailey, "Evolution of Our Native Fruits," and Craig & Hume, "Native Crab Apples and Their Cultivated Varieties," Iowa Acad. Sci., 1899.

BB. *Calyx* falling from the fr.

21. *baccata*, Linn. (*Malus baccata*, Borkh. *Malus microcarpa* var. *baccata*, Carr. *M. baccata* var. *sibirica*, Schneid.). SIBERIAN CRAB. Fig. 3288. Small round-headed tree, with a compact crown, smooth in all its parts at maturity; growth hard and wiry: lvs. ovate to

3286. *Pyrus Soulardii*. ($\times \frac{1}{2}$)

ovate-lanceolate or ovate-acuminate, thin and glabrous, on slender petioles, finely and nearly evenly serrate, bright green: fls. appearing with the lvs. on long and very slender (2–3 in.) greenish pedicels, white, handsome; style mostly longer than the stamens, lightly hairy or glabrous: fr. from the size of a pea to $\frac{3}{4}$ in. diam., on long, hard sts., yellow or red and firm and often translucent in texture, never becoming mellow, the calyx falling away before maturity. Siberia to Manchuria and N. China. B.M. 6112. M.D.G. 1899:454. Gt. 11:202.—Difficult to distinguish from *P. pulcherrima*: larger, becoming a distinct tree, sometimes as large as a large apple tree: lvs. with blunter teeth, and usually much longer, very slender, hard, glabrous petioles: fls. lighter colored, usually white; veneration convolute (lvs. rolled in the bud). It runs into many forms, particularly in fr. Var. *mandshurica*, Maxim. (*Malus baccata* var. *mandshurica*, Schneid.). Low densely branched tree when growing in the open but tall and wide-spreading in forests: lvs. broader, elliptic or round-elliptic, mostly entire, the petiole, rib, and nerves, as well as infl., more or less hairy: style scarcely as long as the stamens: fr. elliptic, about $\frac{1}{2}$ in. diam. Amur region, Korea, Cent. China, Japan. Var. *himalaica*, Maxim. (*Malus baccata* var. *himalaica*, Schneid.). Lvs. very broad-oval, coarsely serrate, more or less hairy underneath, particularly on midrib. W. Himalaya. A handsome form from Korea with pure white large fls., large dark green lvs.

and large dark red fr., is distinguished by Rehder as forma *Jackii*: from var. *mandshurica* it differs in being glabrous.—The Siberian crabs of pomologists belong to *P. baccata*, but to which of the several botanical forms (if to any of them) is not clearly determined; the species is also used in cold countries as a stock on which to graft the common apple. It is a species of great hardiness, withstanding the climate in the Canadian N. W. provinces. It is much subject to blight (pear-blight) and for this reason its usefulness is much limited. Hybrids with *P. Malus* promise a valuable type of apple for cold regions. See Fig. 648, Vol. I, and pp. 569

3287. Mature leaf of *Pyrus Soulardii*. ($\times \frac{1}{2}$)

and 570. The large-fruited pomological crab-apples of the Hyslop and Transcendent type are supposed to be hybrids between *P. baccata* and *P. Malus*, and to these forms the name *P. prunifolia* has been applied but probably erroneously. The *P. cerasifera*, Spach, is of the *P. baccata* group, and is probably a hybrid: it

ripening fr.; from *P. pulcherrima* it is distinguished by the convolute vernation of the glabrous lvs., the color of the larger fls., the shorter sepals, and the glabrous purple pedicels and calyx. In foliage and fls. it much resembles *P. spectabilis*, which, however, differs by its pubescence and the much larger fr. crowned by the persistent calyx. From other species it differs in its polygamous fls. There is at least 1 staminate fl. in each umbel, and this is always terminal; sometimes there are 2 or 3, but the number of staminate fls. rarely exceeds that of the perfect ones. In the staminate fls. there is no trace of reduced pistils. The species was intro. to American gardens about 1863 by G. R. Hall (see p. 1578, Vol. III).

23. *theifera*, Bailey (*Malus theifera*, Rehd.). A small tree with stiff spreading branches, hardy at Boston, resembling a cherry tree when in bloom, the fls. white or light pink (there is a rose-colored form) with purple calyx and the unfolding lvs. purplish: distinguished from *P. Halliana*, its nearest ally, by larger and broader ovate or ovate-oblong or elliptic-ovate sharply glandular-serrate thinner lvs., longer petioles and less slender pedicels, acute or acuminate calyx-lobes, mostly 3 styles, white or bluish fls., and larger frs. China to Assam.—The fr. is globose, light greenish yellow with reddish cheek, ripening in Mass. in Oct.: fls. fragrant. Not yet grown outside botanical collections, but a handsome free-flowering species. Var. *rösea*, Bailey, has rose-colored fls. and is very beautiful.

24. *sikkiménsis*, Hook. f. Small tree, with tomentose branchlets: lvs. ovate to ovate-oblong, 2-3 in. long, not lobed, the apex long-acuminate, abruptly narrowed at base, tomentose beneath, with fine and close sharp-pointed serratures, the petiole much shorter than the blade: fls. 1 in. across, 5-8 in a corymbose cluster, appearing with the lvs., white but pinkish outside, the buds rose-colored; pedicels very slender, $1\frac{1}{2}$ -2 in. long; calyx-tube ellipsoid, the lobes lanceolate and recurved; petals orbicular, claw very short, tomentose; stamens many; styles slender and glabrous, connate below: fr. turbinate, not depressed at base, $\frac{3}{8}$ in. diam., dark red speckled white, the calyx wholly wanting. Himalaya. B.M. 7430.

AA. The oriental "flowering apples" (East Asian, Chino-Japanese) grown in many forms for the ornamental fls. and frs. (Cf. Rehder, *Plantæ Wilsonianæ*, 2:279-95). (Most of these oriental flowering crabs are in cult. only in botanical collections but they are likely to be planted elsewhere, and it is necessary to the determination of most of them that all the others be contrasted.)

B. Lvs. convolute (rolled up in the bud), always undivided.

C. Calyx deciduous from the fr. (In this group belong *P. baccata*, *P. Halliana*, and *P. theifera*; in the first (see No. 22) the calyx-lobes are longer than the tube, narrow-lanceolate, and the fls. white with mostly 5 styles, in these characters being distinguished from one or both of the others.)

22. *Halliana*, Voss (*Malus Halliana*, Koehne). Fig. 3289. Bush or small tree, 6-15 ft. tall, with a loose open crown: lvs. long-ovate, glabrous, leathery, crenate-serrulate, the petioles short: fls. rose-colored, more or less polygamous, hanging on slender reddish pedicels, the calyx-lobes often more or less obtuse, the styles usually 4: fr. size of a pea or somewhat larger ($\frac{1}{4}$ - $\frac{1}{2}$ in. diam.), abruptly contracted into a thickened pedicel, brownish red, ripening late in autumn and containing very large seeds: W. China; cult. in Japan. M.D.G. 1899:457. One of the handsomest of the flowering apples. Var. *Parkmanii*, Bailey (*P. Parkmanii*, Hort.), is the double-fl. form: named for Francis Parkman, the historian, in whose garden near Boston it was first grown in this country. *Malus Hartwigii*, Hort., is a hybrid of German origin, between *P. Halliana* and *P. baccata*.—*P. Halliana* is a beautiful little tree which was recognized among horticulturists before it was described by botanists. The first naming of it in *Pyrus* in such a way as to gain nomenclatorial standing with botanists seems to have been by Voss in Vilmorin's *Blumengärtnerei*, 3d ed., 1896. Rehder distinguishes the species as follows (in Sargent, "Trees and Shrubs," 1:35, from which also Fig. 3289 is reduced): It is allied to *P. baccata*, and *P. pulcherrima*; from the first it is distinguished by the leathery lvs., the color of the fls., the much shorter sepals, the purple calyx and pedicels, and the 4- or 5-celled very late-

3288. *Pyrus baccata*. ($\times \frac{1}{2}$)
No. 21.

3289. *Pyrus Halliana*. ($\times \frac{1}{2}$)

cc. Calyx persistent on the fr.

d. Style glabrous at base: fr. punctate: lvs. sharply and mostly doubly serrate.

25. *Prättii*, Hemsl. (*Malus Prättii*, Schneid.). Young growths whitish hairy but becoming glabrescent: lvs. 3-4 in. long, the long petiole extra, ovate-lanceolate to ovate or elliptic, acuminate-acute, the base usually rounded, finely somewhat double-serrate with callous serrations: fls. medium size, in many-fl'd. terminal subsessile clusters, slender-pedicelled; calyx-lobes acuminate, white-silky inside; petals $\frac{1}{2}$ in. long, short-clawed, rounded at apex, conspicuously veined; styles 5, glabrous: fr. about $\frac{1}{2}$ in. long, ovoid, punctate, the calyx persistent. China.

dd. Style villous at base: fr. smooth and not punctate: lvs. simply serrate or crenate-serrate.

e. Lvs. membranaceous or thin in texture, dull above: calyx-lobes acuminate and longer than the tube.

26. *prunifolia*, Willd. (*Malus prunifolia*, Borkh. *M. hybrida*, Loisel.). For years considered to be a hybrid of *P. baccata* and *P. Malus* or other species, but a plant which he considers to be a variety of it (var. *Rinki*) having been found wild in China leads Rehder to the conclusion that it is a good natural species; *P. prunifolia* itself is yet known only as a cult. plant: tree,

3290. *Pyrus prunifolia* var. *Rinki*.
($\times \frac{1}{2}$). No. 26.

glabrous or the pedicels and calyx more or less tomentose: lvs. much like those of *P. baccata*, but slightly pubescent on veins below and glabrous at maturity: small tree: lvs. 2-3 in. long, ovate to obovate or nearly orbicular, somewhat acute to short-acuminate, the margin with small close somewhat unequal serratures: fls. 6-10 in a sessile cluster, on pedicels 1-1 $\frac{1}{2}$ in. long, white, 1 $\frac{1}{2}$ in. across; calyx-tube obconical, the lobes or sepals lanceolate; petals orbicular or oblong; styles 5, connate below the middle: fr. about 1 in. diam., globose to ovoid, with cavity at base, green, yellow, or red. Probably Siberia. B.M. 6158.

Var. *Rinki*, Bailey (*Malus pumila* var. *Rinki*, Koidz. *M. prunifolia* var. *Rinki*, Rehd. *M. yezoensis*, Koidz. *M. Matsumura*, Koidz. *M. Ringo*, Carr. *Pyrus Ringo*, Wenz. *P. praecox*, Miq.). CHINESE APPLE. Figs. 3290, 3291. Wide-spreading small tree, to 15 or 18 ft. high, more pubescent than the type (*P. prunifolia*) and representing a more southern range, the petioles shorter and the fls. pink or pinkish rather than white. China. B.M. 8265.—This tree yields an edible apple, sometimes as much as 1 $\frac{1}{2}$ in. diam., of a greenish or yellowish color and with a bitter-sweet flavor; it was formerly grown in Japan for its fr., but its cult. has been discontinued since the intro. of the European apple, yet is now used as stocks for the imported kinds. In China it is still sparingly cult. In botanical characters the plant is much like *P. Malus*, but is distinguished by the much longer fr.-stalk, more sharply serrate and usually less tomentose lvs., the apex of the fr. not

sunken but with a raised calyx which is thickened and fleshy at the base.

EE. Lvs. paper-like in texture, shining above: calyx-lobes shorter than the tube or only equalling it.

27. *spectabilis*, Ait. (*Malus spectabilis*, Borkh. *M. sinensis*, Dum.). CHINESE FLOWERING APPLE. Fig. 3292. Small tree, with

darker-colored fls. than those of the apple (the opening fl.-buds almost coral-red), and blooming earlier, making an erect vase-like head: lvs. narrower, oval to oval-oblong, slender-stalked, nearly glabrous on both surfaces or becoming so, usually more closely serrate than those of the apple: pedicels and calyx-tube nearly or quite glabrous: fr. roundish or round-oval, without a cavity at the base, reddish yellow, sour. Probably China and Japan, although unknown wild and very little grown in those countries although well known in cult. in Eu.; the plant called by this name in Japan is probably *P. Halliana* or *P. micromalus*. B.M. 267. L.B.C. 18:1729. Gn. 21, p. 46. Gng. 3:273. G.F. 1:272.—A very handsome early-blooming tree, of which the double-fl'd. and semi-double forms are most prized. *P. Malus* itself has been disseminated under the name of *P. spectabilis*. Hardy in the northern states. Var. *Riversii*, Booth, has very large half-double bright rose-red fls.

3291. *Pyrus prunifolia* var. *Rinki*.
($\times \frac{1}{2}$)

28. *micromalus*, Bailey (*Malus micromalus*, Makino. *M. spectabilis* var. *micromalus*, Koidz. *Pyrus Kaïda*, Mouill. *Malus microcarpa* var. *Kaïda*, Carr. *M. spectabilis* var. *Kaïda*, Sieb.). Fig. 3293. Apparently a hybrid, *P. spectabilis* being undoubtedly one of the parents, and probably *P. baccata* or *P. floribunda* the other. From *P. spectabilis* it is distinguished by the narrower lvs. which are gradually narrowed at the base into a slender petiole, by tomentose pedicels and calyx, and the subglobose fr. which has a depression at base and apex, the calyx sometimes deciduous. Cult. in Japan, and said to have been intro. from China;

3292. *Pyrus spectabilis* ($\times \frac{1}{2}$). No. 27.

unknown in the wild.—A useful and showy plant, bearing profusely of bright red fls., with red calices and pedicels, and holding its many little frs. well into winter or even all winter.

BB. Lvs. *conduplicate* (folded together lengthwise face to face in the bud), those on the strong shoots often lobed.

c. Calyx persistent.

29. *Tschonoskii*, Maxim. (*Malus Tschonoskii*, Schneid.). Fig. 3294. Tree, 30–40 ft. with erect and open habit: lvs. ovate-acuminate, coarsely serrate, with sharp teeth, shining and pilose above although tomentose when young, somewhat tomentose beneath: fls. 2–5 together, white tinged rose, on whitish hairy pedicels about $\frac{1}{2}$ in. long; calyx-tube whitish hairy, the lobes or sepals ovate-acute, spreading in fl.; petals about $\frac{1}{2}$ in. long; fr. obovoid, about 1 in. diam.; calyx-lobes persistent, erect or nearly so, white-tomentose, 1 in. or less diam., yellow with a rosy cheek. Japan. B.M. 8179. G. F. 7:55 (reduced in Fig. 3294).

3293. Fruit of *Pyrus micromalus* in winter. ($\times \frac{1}{2}$)

30. *yunnanensis*, Franch. (*P. Vetchii*, Hort. *Malus yunnanensis*, Schneid. *Eriolobus yunnanensis*, Schneid.). Distinguished from *P. Tschonoskii* by its smaller fls. in many-fld. clusters, much smaller frs. which are red and with reflexed calyx-lobes, and by the lvs. which are more distinctly lobed and sharply close-serrate: a handsome tree with spreading branches: lvs. simple, broadly ovate, with closely or finely toothed lobes: fr. small, $\frac{1}{2}$ in. or less long, produced abundantly. China. G.M. 56:897.

cc. Calyx deciduous.

d. Styles glabrous at base: fr. ovoid: lvs. prominently lobed.

31. *transitoria*, Batal. (*Malus transitoria*, Schneid.). Young twigs, lvs., and infl. more or less felty: lvs. more or less acute, 3-lobed, about 1 in. diam., petiole about $\frac{3}{4}$ in. long: infl. 3–8-fld.; peduncle, receptacle, and calyx felty; petals broad-oblong, somewhat emarginate, small-clawed, 5 times as long as the calyx; stamens 15; styles 5 (rarely 4), more or less grown together, naked: fr. globose, more or less hairy, about $\frac{1}{4}$ in. diam. China. Var. *toringoides*, Bailey (*P. transitoria* var. *toringoides*, Rehd.), is larger and more vigorous, the lvs. partly entire, frs. larger. W. China.

dd. Styles villous at base: fr. ovoid: lvs. prominently lobed.

32. *kansuensis*, Batal. (*Malus kansuensis*, Schneid. *Eriolobus kansuensis*, Schneid.). A distinct species, marked by the usually broad-ovate 3–5-lobed and sharp-serrate glabrous or glabrescent lvs. which are 3-nerved at base, and by the ovoid red fr. from which the calyx is deciduous: young twigs glabrous, red-brown; buds of the same elongate, acute; scales only finely ciliate: lvs. dark green above, somewhat glandular on the nerves, somewhat paler beneath, glabrous or slightly hairy on the nerves, subrotund in outline, upper half palmately 3-lobed, lobes triangular, acute, margin serrate, the side lobes somewhat shorter; petiole $1\frac{1}{2}$ in. or less long: infl. a false umbel; calyx

acute, equaling the corolla; petals round, short-clawed, more or less hairy inside; stamens 20; styles 3, hairy and grown together at base: fr. purple, 3-celled, about $\frac{1}{2}$ in. long. China.

DDD. Styles villous at base: fr. subglobose.

E. Fls. white, the petals nearly orbicular and at base contracted into a claw.

33. *Sargentii*, Bean (*Malus Sargentii*, Rehd.). A low bush, much branched, the branches rigid and often spinescent: lvs. ovate to elliptic-oblong or ovate-oblong, about 2–3 in. long, sharply and unequally serrate, slender-petioled, those on the vigorous branches mostly ovate and 3-lobed: fls. pure white, 1 in. across, in 5- or 6-fld. clusters, on glabrous pedicels about 1 in. long; calyx-tube and lobes glabrous outside and villous inside, the lobes ovate-lanceolate and acuminate; petals about twice as long as calyx-lobes, oval, short-clawed, glabrous; stamens 15–20; styles usually 4 (rarely 3 or 5), connate and villous below the middle: fr. subglobose, $\frac{1}{2}$ in. or less diam., dark red with a slight bloom. Japan. S.T.S. 1:37. G.C. III. 57:291 (as *P. Malus Sargentii*); 58:309 (fr.). G.M. 58:278.

EE. Fls. reddish (varying to nearly white), the petals cuneate or rounded at base, obovate or oblong.

34. *Sieboldii*, Regel (*Malus Sieboldii*, Rehd. *Pyrus Toringo*, Sieb. *M. Toringo*, Sieb. *P. Mingo*, Sieb. *M. microcarpa* var. *Toringo*, Carr.) Fig. 3295. Shrub: lvs. ovate or oblong-ovate in outline, pubescent, becoming colored in autumn, strongly notched or lobed on either side at or below the middle, the middle lobe often notched again near the top, the remaining margins sharply dentate: fls. small, bluish, on slender sts.; styles 3–4, connate at base; sepals triangular-ovate or lanceolate, about equaling the tube: fr. the size of a pea, shedding its calyx, yellow or red. Japan. R.H. 1870:451; 1881, p. 296. Gn. 34, p. 206. M.D.G. 1899:456.—Grown mostly for ornament, but lately recommended as a hardy stock upon which to dwarf the apple. In Japan, the little frs. are gathered after frost and preserved. Upon the fr.-spurs, the lvs. are sometimes only toothed, but upon barren or strong shoots they are prominently lobed and suggest the lvs. of hawthorns. Var. *arborescens*, Bailey (*Malus Sieboldii* var. *arborescens*, Rehd.), which is widely distributed in Japan, differs from the type in its more tree-like habit (to 30 ft.), less pubescent, lvs. somewhat larger and usually less deeply divided and often lobed only on the ends of strong shoots, fls. often nearly white, frs. yellow or red. Var. *calocarpa*, Bailey (*M. Sieboldii* var. *calocarpa*, Rehd.), has large handsome bright red fr. and large fls.: lvs. on fruiting branches

3294. *Pyrus Tschonoskii* ($\times \frac{1}{2}$). No. 29.

mostly ovate-oblong and crenate-serrulate, those on the vigorous shoots mostly 3-lobed with the lateral lobes short and broad: distinguished from *P. Zumi* by the 3-4 rather than 4-5 styles and by the lobed lvs.

35. *Zumi*, Mats. (*Malus Zumi*, Rehd.). Low and much-branched tree, to 20 ft., with rounded head and twiggy growth, sometimes 40 ft. tall and with more ascending branches: lvs. long-petioled, oblong to ovate-oblong or elliptic-oblong, $1\frac{1}{2}$ –3 in. long, acute at apex, rounded or narrowed at base, entire or somewhat crenate-serrate, yellowish green above and light green beneath, soon glabrous, those on the ends of vigorous branches lanceolate and usually coarsely dentate: fls. white or slightly pinkish, borne in profusion, about 1 in. across, on loosely villous or glabrous pedicels about 1 in. long; calyx-lobes lanceolate, villous inside and less so outside; petals elliptic, obtuse, rounded at base but short-clawed, opening pink but becoming pure white; stamens about 25; styles 4 or 5, connate for one-third their length, densely villous: fr. $\frac{1}{2}$ in. or less diam., globose, red, the calyx deciduous. Mountains of Cent. Japan. S.T.S. 1:91.—Differs from both *P. Sargentii* and *P. Sieboldii* in the oblong lvs. which are not at all or only slightly lobed, and slender petioles; from *P. Sargentii* also in longer petals rounded at base, glabrous lvs., longer petioles, and erect branches; from *P. Sieboldii* also in differences in foliage, larger fls., larger broader petals rounded at base.

36. *pulcherrima*, Aschers. & Graebn. (*P. floribunda*, Kirchn., not Lindl. *P. Malus floribunda*, Hort. *Malus floribunda*, Sieb. *M. microcarpa* var. *floribunda*, Carr.). FLOWERING CRAB. Unknown in the wild but long in cult., and perhaps a hybrid of *P. baccata* and *P. Sieboldii*; intro. from Japan, where it seems not to be recognized, Rehder finding that what the Japanese botanists know under this name is *P. Halliana*: shrub or sometimes a small tree, often thorny: young growths glabrous or very soon becoming so: lvs. ovate and usually acuminate, the petioles rather thick and reddish and usually not much if any more than 1 in. long on the leading young shoots, the margins very sharply serrate or incised-serrate, not lobed, usually thickish, shining above and glabrous (or soon becoming so) beneath: fls. rose or rose-red, appearing with the lvs., produced in great abundance and very showy; styles nearly always 4, very rarely 3 or 5, connate to the middle: fr. usually about the size of a pea, on long, slender stalks, red, not persisting till winter. China. R.H. 1866:311; 1871:591; 1881, p. 296. F.S. 15:1585. G.F. 1:152; 2:523. A.G. 13:437; 18:437. F.E. 9:573. M.D.G. 1899:454.—The name of this species is somewhat in confusion. It has been known as *P. floribunda*, but Lindley earlier gave this name to a very different plant, of the section or genus *Aronia* (see p. 396, Vol. I), and the present species must take a new name. *P. pulcherrima* is one of the best of all early spring-flowering bushes or small trees, and is now common in gardens. The semi-double forms often improperly receive the names *Halliana* and *Parkmanii*. It makes a broad round-headed great bush, with handsome rose-colored buds and whitish expanded fls. *P. atrosanguinea*, Spæth, is a handsome floriferous species of doubtful origin. It is probably *P. Halliana* $\times$ *P. Sieboldii* (Koehne supposes it to be *P. Halliana* $\times$ *P. fusca*): resembles in general *P. pulcherrima*, but differs in its deep carmine fls. not fading to white, rather narrower petals, shorter ovate and somewhat obtuse calyx-lobes, more shining and finally glabrous lvs., those lvs. at the end of vigorous shoots sometimes slightly 3-lobed: fr. dark red. Gt. 47:1448.

Var. *Scheideckeri*, Bailey (*Pyrus Scheideckeri*, Spæth. *Malus Scheideckeri*, Zabel), originated at Scheidecker's nursery at Munich from seeds of *P. pulcherrima*, but shows evidences of hybridity with some closely related species (probably with *P. prunifolia*) or else indicating

the hybrid origin of *P. pulcherrima* itself: small tree of pyramidal habit, producing abundantly of large semi-double tinged pink fls.: young branchlets slightly pubescent: lvs. ovate, acuminate, about 3 in. long, scattered-pubescent beneath, petiole hairy, margins coarsely sharp-serrate or double-serrate: fr. globose, $\frac{3}{4}$ in. diam., the calyx usually persistent. Gng. 6:308. A.F. 13: 1398. Gn. M. 10:20. G.M. 44:274; 54:861; 55:820; 57:256. G. 26:203; 27:234. Gn. W. 21: suppl. July 23. Gt. 53:1529 and p. 418.

Var. *Arnoldiana*, Bailey (*Malus floribunda* var. *Arnoldiana*, Rehd.). Originated at the Arnold Arboretum, Boston, as a seedling of *P. pulcherrima*: fls. more than one-half larger than in the type, pale rose: fr. much larger, yellow: of bushy habit.

3295. *Pyrus Sieboldii* ($\times \frac{1}{2}$). See No. 34.

AAA. The American native wild apples or crabs, sometimes planted in grounds but only *P. ioensis* yielding marked horticultural forms: fls. large, pink, fragrant: lvs. for the most part coarsely toothed and more or less lobed or notched: calyx persistent (exception in *P. fusca*). Not all these species are in cult. outside botanical collections, but they have been so much confused that it is necessary to describe all of them in order clearly to distinguish them.

B. *Calyx deciduous from the fr.: western.*

37. *fusca*, Raf. (*P. rivularis*, Douglas. *Malus rivularis*, Roem.). Shrub or small tree, sometimes 30–40 ft. tall, the young growths more or less pubescent: lvs. ovate-lanceolate, acute or acuminate, very sharply and strongly serrate, often 3-lobed or notched on the strong shoots, pubescent beneath: fls. white, on slender pubescent pedicels, appearing when the lvs. are nearly or quite full grown, nearly or fully 1 in. across: fr. oblong, $\frac{3}{4}$ in. or less long, yellow or greenish, the calyx-lobes caducous. N. Calif. to Alaska. S.S. 4:170.—Accord-

ing to Sargent, *P. fusca* "grows usually in deep, rich soil in the neighborhood of streams, often forming almost impenetrable thickets of considerable extent, and attains its greatest size in the valleys of Washington and Oregon." The fr. is eaten by Indians. Var. *lévipes*, comb. nov. (*Málus fusca* var. *lévipes*, Schneid. *M. rivulàris* var. *lévipes*, Koehne. *Pyrus rivulàris* var. *lévipes*, Nutt.), has glabrous infl. and outer surface of calyx. Var. *diversifolia*, comb. nov. (*Pyrus diversifolia*, Bong. *Málus fusca* var. *diversifolia*, Schneid. *M. rivulàris* var. *diversifolia*, Koehne), has white-tomentose infl. and outer surface of calyx. *Málus Dawsoniana*, Rehd., is a supposed hybrid of *P. fusca* and *P. Malus* raised at the Arnold Arboretum and named for Jackson Dawson. In habit it is like *P. fusca*, but the lvs. are usually broader and more oval, more crenately serrate and rarely lobed; fls. and frs. nearly twice as large, the calyx persistent. S.T.S. 2:91.

BB. Calyx persistent: eastern.

C. Foliage glabrous at maturity.

D. Apex of lvs. rounded and obtuse; margins crenate-serrate.

38. *angustifolia*, Ait. (*Málus coronària*, Brit. *M. angustifolia*, Michx. *M. sempervirens*, Desf. *P. sempervirens*, Willd. *M. microcarpa* var. *sempervirens*, Wenz.). Small tree, to 20 or 30 ft.: lvs. lance-oblong, crenate-serrate or almost entire, not lobed or only slightly so, thick and partially evergreen, rounded at apex, cuneate at base: fls. 1 in. across, fragrant, in few-fl. umbels, slender-pedicelled; calyx-tube glabrous or pubescent outside, the lobes narrow-acuminate and with rigid points and tomentose inside; petals narrow-obovate, slender-clawed; styles tomentose below: fr. subglobose to slightly pyriform, $\frac{3}{4}$ –1 in. diam., with cavities at both ends, yellow-green and fragrant. Va. to Fla. and Miss. S.S. 4:169. B.R. 1207. A double-fl. form is sometimes described and figured as *P. angustifolia*, but it is properly *P. ioensis* (No. 44). Var. *pubérula*, Bailey (*M. coronària* var. *pubérula*, Rehd. *M. angustifolia* var. *pubérula*, Rehd.), in Miss. and La., differs mostly in its pointed lvs., which are lightly pubescent beneath when young, and by the slightly villous pedicels.

DD. Apex of lvs. acute or acuminate.

E. Lvs. not lobed, or sometimes slightly so at end of vigorous shoots.

39. *platycarpa*, Bailey (*Málus platycarpa*, Rehd.). Small tree, to 20 ft., with spreading unarmed branches, young growths thin-tomentose but becoming glabrous:

3296. *Pyrus lancifolia*.
($\times \frac{1}{2}$)

lvs. ovate to elliptic, rounded at base, the apex rounded but with short acute point, sharply and mostly doubly serrate, those on vigorous shoots broad-ovate and usually with several pairs of very broad triangular lobes: fls. 3–6 in raceme-like umbels, about $\frac{1}{2}$ in. diam., on glabrous pedicels 1–1 $\frac{1}{2}$ in. long; calyx-tube obconic and glabrous, the lobes or sepals lanceolate-acuminate and longer than the tube and densely tomentose within though glabrous without; petals orbicular-ovate, usually dentate; styles 5, villous below the middle and connate for one-third their length: fr. depressed-globose with deep depressions at both ends, broader than long (2 in. diam.), with persistent calyx, sometimes used for preserves. N. C. to Ga. in fertile bottoms. S.T.S. 2:189.—Mostly closely related to *P. coronaria*, but easily distinguished from this as well as from other species by the broad and large lvs. which are rounded and abruptly acuminate at apex, and never lobed, and by its very large fr.

3297. *Pyrus glaucescens*. ($\times \frac{1}{2}$)

Var. *Hoopesii*, Bailey (*Málus coronària* var. *Hoopesii*, Rehd. *M. platycarpa* var. *Hoopesii*, Rehd.). Differs in pubescent calyx, oval to elliptic lvs. only slightly or not at all lobed, and by the larger fr. Known only in cult.

40. *lancifolia*, Bailey (*Málus lancifolia*, Rehd.). Fig. 3296. Small tree, to 25 ft., with spreading spiny branches, the branchlets slightly pubescent or nearly glabrous: lvs. ovate-lanceolate to oblong-lanceolate, 1 $\frac{1}{2}$ –3 in. long, at the apex acute or short-acuminate, at the base rounded or broad-cuneate, either finely or coarsely serrate and frequently doubly serrate with the short teeth pointing forward, those on vigorous shoots ovate or oblong-ovate and often slightly lobed: fls. 3–6, in umbel-like racemes, white or rose, something over 1 in. across, on slender glabrous pedicels 1 in. or more long; calyx-tube obconic and on the outside glabrous, the lobes or sepals oblong-lanceolate and exceeding the tube and villous-tomentose within but glabrous without; petals oval, long-clawed; styles 5, densely villous below the middle: fr. subglobose, about 1 in. diam., on slender drooping pedicels, green and waxy. Pa. and Va. to Mo. S.T.S. 2:158 (a sprig of which is reduced in Fig. 3296).—Distinguished from *P. coronaria* (*P. angustifolia*) by the shape of the lvs., which are acuminate and less coriaceous, by the narrower and longer calyx-lobes, styles villous to middle, and by the different fr.

EE. Lvs. distinctly lobed, particularly on the strong shoots and sometimes on the flowering branchlets.

41. *glaucescens*, Bailey (*Málus glaucescens*, Rehd.). Fig. 3297–3299. Small tree or large shrub, with twiggly spiny head, the branchlets glabrous or at first slightly pubescent: lvs. triangular-ovate or ovate, 2–3 $\frac{1}{2}$ in. long, at the apex acute or short-acuminate or even rounded, at base truncate villous-tomentose when young but becoming glabrous, glaucescent beneath, more or less triangular-lobed, coarsely serrate with abruptly acuminate teeth, the lowest pair of veins arising some distance above the base of the blade; petioles slender, soon becoming glabrous: fls. white or pink, 5–7 in umbel-like racemes, appear when lvs. are nearly full-grown, on slender glabrous pedicels 1 in. or so long; calyx-tube thinly villous outside, the lobes oblong-

lanceolate-acuminate and densely tomentose within; petals oval, rounded at top, more or less gradually narrowed into a claw; styles slightly shorter than the stamens; fr. flattened and concave at both ends, broader than long, not angled, yellow and waxy at maturity, fragrant. N. Y., and southward in the Appalachian region to N. C.; early-flowering. S.T.S. 2:157. This species is often confused with the following, but is easily distinguished by its distinctly lobed crataegus-like lvs. whitish on their under side.

42. *coronaria*, Linn. (*Malus fragrans*, Rehd. *Malus coronaria*, Mill.). Closely related to *P. glaucescens*, but differing in less deeply lobed more elongated lvs. which are green and not glaucous beneath at maturity, glabrous calyx-tube, and the fr. being strongly ribbed at the deeply sunken apex. N. Y. to Ala. B.M. 2009. B.R. 651. S.S. 4:167 (all as *P. coronaria*). R.H. 1884, p. 104 (as *P. microcarpa coronaria*). Gn. 29, p. 395; 34, p. 206.—The fr., which is produced in abundance, was often buried by the early settlers for use in the spring, when its acerbity was largely extracted; and it was sometimes used for cider. It is also useful for jellies and preserves. The species was probably never intro. into cult. for its frs., although it has been long grown for ornament and under domestication the apples are often twice their natural size. Var. *elongata*, Bailey (*M. fragrans* var. *elongata*, Rehd. *M. coronaria* var. *elongata*, Rehd.). Lvs. narrow-triangular and distinctly incised-serrate or lobed. N. Y. to N. C. There is a form with semi-double fls. and one (var. *aucubæfolia*, Bailey) with variegated lvs. An attractive species. For recent discussions of the nomenclature of this species and No. 38, see Jackson, G.C. III. 55, p. 294, and Rehder, M.D., 1914, pp. 260-61.

43. *glabrata*, Bailey (*Malus glabrata*, Rehd.). A southern representative of *P. glaucescens*, native from N. C. to Ala., distinguished by the lvs. light green and not glaucescent on the lower surface and rather thin, glabrous, deeply lobed, distinctly cordate at base, and the lowest pair of lateral veins springing from the very base of the blade: calyx-tube glabrous and purple;

cc. *Foliage tomentose or villous or pubescent at maturity, at least on the vigorous shoots, the lvs. thickish and strongly veined.*

44. *ioënsis*, Bailey (*P. coronaria* var. *ioënsis*, Wood. *Malus ioënsis*, Brit. *Malus coronaria* var. *ioënsis*, Schneid. *P. iowënsis*, Carruth?). PRAIRIE OR

3299. *Pyrus glaucescens*.
($\times \frac{1}{2}$)

WESTERN CRAB-APPLE. Fig. 3300. Small tree, the younger parts gray-woolly: lvs. from ovate-oblong to elliptic-obovate, irregularly and mostly bluntly toothed and the larger ones marked with right-angled notches of shallow lobes, very tomentose below or becoming rusty and rarely glabrate with age, the petioles short and stout and pubescent: fls. usually upon shorter pedicels which, like the calyx, are tomentose: fr. oblong or at least never flattened lengthwise, sometimes angular, larger than in *P. glaucescens* and clinging later to the tree, dull heavy green with numerous light-colored dots on the skin, the surface having a greasy feel, the st. short and thick as compared with No. 41, and set in an oblique cavity, the basin narrow and shallow, with variable corrugations and a closed and pubescent calyx, the flesh sour and austere. Wild in low or flat lands in the Mississippi Valley, the typical form, as understood by Rehder, ranging from Minn. and Wis. to Neb., Kans., and Mo. B.M. 8488. S.S. 4:168 (frs. too flat).—Fr. appropriated by the settlers, but the species is probably not in cult. for its fr., although a late-blooming double-fl. variety has been lately intro.—Bechtel's crab, sometimes referred to *P. angustifolia*. G.C. III. 25:397. R.B. 38:185. R.H. 1910:60. *P. ioënsis* is a variable species, in some of its forms difficult to separate from *P. coronaria*, *P. angustifolia*, and other species. Var. *Palmeri*, Bailey (*M. ioënsis* var. *Palmeri*, Rehd.). Small and slender tree, to 18 ft., differing from the type chiefly in the smaller oblong more thinly pubescent lvs. which are rounded at apex, and those on the flowering shoots not lobed and crenate-serrate. Mo. Var. *spinosa*, Bailey (*M. ioënsis* var. *spinosa*, Rehd.). Dense bushy shrub, 6-8 ft., with slender spiny branches: differs from var. *Palmeri* in a shrubby habit, smaller lvs. and fls., and glabrescent calyx: from *P. coronaria* (*P. angustifolia*) in the pubescence of the lvs., serrate or serrulate lf.-margins and lobed ovate lvs. of the strong shoots. Mo. Var. *Bushii*, Bailey (*M. ioënsis* var. *Bushii*, Rehd.). Differs in bearing less deeply lobed lvs. than the type, which are glabrescent: from var. *Palmeri* it differs in having oblong-lanceolate acute glabrescent lvs. Mo. Var. *crenisserrata*, Bailey (*M. ioënsis* var. *crenisserrata*, Rehd.), is a slender spineless tree with branches villous when young, and crenate-serrate or entire elliptic-ovate to oblong-ovate lvs., or those on the vigorous shoots somewhat doubly serrate: calyx

3298. A wild crab of the East.—*Pyrus glaucescens* ($\times \frac{3}{8}$). No. 42.

petals suborbicular or broadly ovate or rarely oval, abruptly contracted into a short claw, often erose-denticulate; styles 5, slightly longer than the stamens: fr. depressed-globose and slightly angled, distinctly ribbed at the deeply sunken apex. S.T.S. 2:188.

tomentose. La. Var. *texana*, Bailey (*M. ioensis* var. *texana*, Rehd.). Small much-branched tree, to 18 ft., or sometimes a shrub forming thickets, with densely tomentose branchlets which become glabrescent the first or second year, differing from the type in having smaller and much broader lvs. that are not at all or only slightly lobed and densely villous at maturity. Texas, representing the southwestern extension of the species.

45. *bracteata*, Bailey (*Malus bracteata*, Rehd.). Tree, to 30 ft. or more tall, forming a broad head: a glabrescent form: lvs. elliptic-ovate to oblong-ovate, serrate or incisely serrate and less deeply so than in *P. ioensis* and with less deep lobing, sometimes slightly lobed near the base, those on the vigorous shoots usually ovate and with recurved very short lobes on either side and the margins commonly only slightly serrate, the foliage glabrous or glabrescent except the slightly pubescent lvs. at the end of strong shoots: racemes 3-5-fld., the pedicels about $\frac{1}{2}$ in. long, glabrous or nearly so and bearing subulate bractlets $\frac{1}{4}$ - $\frac{1}{2}$ in. long which persist during flowering. Mo.

P. alniifolia, Franch. & Sav.=Sorbus.—*P. americana*, DC., and *P. Aucuparia*, Ehrh.=Sorbus.—*P. arbutifolia*, Linn. f.=Aronia.—*P. Aria*, Ehrh.=Sorbus.—*P. Bûnyardii*, Hort., said to be a hybrid of which *Chænomeles Maulei* is one parent, and therefore to be referred to that genus: described as having striking chamois-red fls. of large size.—*P. cardinalis*, Hort.=*Chænomeles japonica* var. *cardinalis*.—*P. Cydonia*, Linn.=Cydonia.—*P. domestica*, Ehrh.=Sorbus.—*P. florentina*, Sarg. (*Crataegus florentina*, Zucc. *Malus florentina*, Schneid. *Pyrus crataegifolia*, Savi. *Malus crataegifolia*, Koehne), considered by some writers to be of the *Malus* section, by others to belong to Sorbus, and by still others to be a hybrid between *Pyrus* and Sorbus (probably *Sorbus torminalis* × *Pyrus Malus*) is a bush or small tree, local in N. Italy: lvs. broad-ovate in outline, with several sharp lobes: fls. white, about 1 in.

across, in open terminal corymbs, opening very late: fr. $\frac{1}{4}$ in. long, elliptic-oblong, red. B.M. 7423. G.C. III. 59:7.—*P. Fölgneri*, Lev.=Sorbus.—*P. germanica*, Hook. f.=Mespilus.—*P. L. H. B.

PYXIDANTHERA (Greek, *a small box* and *anthera*; the anthers opening transversely like the lid of a box). *Diapensiaceæ*. PYXIE. FLOWERING MOSS. PINE-BARREN BEAUTY. An evergreen creeping plant found in cushion-like masses in the sandy pine lands of N. J. to N. C. When it flowers in early April to early May, its white starry blossoms dot the light green or brownish green lf. and st. cushions. It grows best in moist sandy soil in the full sunlight and sometimes on gravel slopes of slight inclination. When growing amongst fallen lvs., its sts. become longer and the whole plant more open in character. The plant is rarely cult., although adapted to rock-gardens in sandy or gravelly pockets. Related to *Diapensia*, an alpine plant, and slightly to *Galax*. The only species is *P. barbulata*, Michx. An evergreen herb with depressed prostrate nearly glabrous sts., much branched at the base and creeping: lvs. numerous, blades leathery, linear-oblan- ceolate, or linear-elliptic, imbricated, small, $\frac{1}{4}$ in. long: calyx campanulate, lobes 5, oblong, obtuse; corolla white, tube oblong-campanulate, petals 5, spatulate to obovate, spreading; anthers of 5 stamens yellow, opening transversely; ovary 3-celled: caps. 3-valved, few-seeded. B.M. 4592. Mn. 8:33. B.B. 2:583. Gn. 27, p. 209. G. 36:649. J.F. 2:150.

JOHN W. HARSHBERGER.

3300. *Prairie States crab*.—*Pyrus ioensis* ($\times \frac{1}{2}$). No. 44.

Q

QUAMÀSIA (*quamash*, the Indian name). *Liliacæ*.

A name given by Rafinesque in 1818 to the plants that Lindley, in 1832, called *Camassia*. On the principle of fifty years of accepted usage, the name *Camassia* is retained in the "nomina conservanda" of the International Botanical Congress (Vienna), and under that name the plants are treated in Vol. II. One species, variously known as *Camassia esculenta*, *Quamasia esculenta* and *Q. hyacinthina*, is native in the eastern United States, but the most showy species are from the Pacific side of the continent.

QUÁMOCLIT (Greek, *a dwarf kidney bean*). Including *Calbda* and *Mina*. *Convolvulacæ*. Annual, or in tropical regions some perennial twining vines;

most of them of easy culture, of rapid growth, and with a profusion of small flowers.

The genus differs from all other *Convolvulacæ* by its axillary often 2-forked clusters of fls., the thickened pedicels of some species, the slender corolla-tube not expanding at the base, the limb of the corolla salverform or cup-shaped, stamens and style exerted and often declinate.—About 10 species. *Q. pinnata* is the best-known species, often used to advantage upon arbors, verandas, walls, or on screens in the conservatory.

A. *Sepals without awns; pedicels thickened: lvs. pinnately divided.*

pinnata, Bojer (*Ipomæa Quámoclit*, Linn. *Q. vulgaris*,

3301. *Quamoclit pinnata*. (×½)

Choisy. *Q. Quámoclit*, Brit.). **CYPRESS-VINE**. **INDIAN PINK**. Fig. 3301. St. smooth, slender, twining to a height of 10–20 ft.: lvs. short-petioled or sessile; peduncles few-fl., commonly much longer than the petioles: corolla 1–1½ in. long, scarlet, the tube narrowly funnel-form, inflated above; the limb nearly flat, 5-lobed. July–Oct. Naturalized from Trop. Amer., Va. to Fla., west to Kans. and Texas; sparingly escaped from cult. farther north. B.M. 188 (as *Convolvulus Nil*); 244. Gn. 29, p. 33.—Beautiful in fl. and foliage but usually does not succeed well in the N. unless started early in the hot-house and transplanted. Var. *álba*, Hort., has white fls.

AA. *Sepals awned: lvs. entire or lobed.*

B. *Corolla-limb expanding abruptly from a slender tube, cup-shaped, ½ in. broad or broader.*

coccínea, Moench (*Ipomæa coccínea*, Linn.). **STAR IPOMÆA**. Fig. 3302. St. freely twining for 10 ft.: lvs. slender-petioled, entire or angulate, acuminate: peduncle 2–6 in. long, few- to several-fl.; corolla ½–¾ in. wide, salverform; limb obscurely lobed, scarlet with yellow throat. Aug.–Oct. Apparently naturalized from Trop. Amer., on river banks in the Middle and South Atlantic states; probably indigenous to N. Mex. and Ariz. B.M. 221.—Fls. are produced in abundance, but are very small.

Var. **hederifolia**, House (*Ipomæa hederifolia*, Linn. *Ipomæa coccínea* var. *hederifolia*, Gray. *Mina sanguinea*, Hort.). Fig. 3303. This Plains form of the species has angulate, 3-lobed or even 3–5-parted lvs., and fls. usually larger. B.R. 9. B.M. 1769. I.H. 41, p. 159.—It is superior to the type for ornamental purposes.

Var. **lutèola**, House (*Ipomæa lutèola*, Jacq. *Ipomæa coccínea* var. *lutea*, Hort.). Fls. yellow, an inch long. Varies to orange in color.

BB. *Corolla-limb expanding funnel-form from a slender bent tube: lvs. 3-lobed.*

c. *Tube of corolla nearly 2 in. long, the limb 5-angled, scarlet.*

grandiflora, Don (*Ipomæa Finis*, Cham. & Schlecht.). A perennial vine with cordate-hastate, 3-lobed lvs., finely pubescent: peduncles elongated, bearing 3–9 scarlet fls.: corolla about 2 in. long, slender, bent, expanding into a 5-angled limb less than an inch broad. S. Mex.

cc. *Tube of corolla scarcely 1 in. long, yellowish, with a purplish, deeply 5-lobed limb.*

vitifolia, Don (*Calbda vitifolia*, Cav.). A perennial twining glabrous vine: lvs. entire or 3-lobed, the middle lobe constricted below: peduncles elongated, several-fl.: corolla about 1 in. long, the yellowish tube expanding above into a scarlet, deeply 5-lobed limb, the exerted stamens elongated and declinate. S. Mex.

BBB. *Corolla-limb cylindrical and bent, longer than the limb, yellow tinged with red.*

lobata, House (*Mina lobata*, Llav. & Lex. *Q. Mina*, Don. *Ipomæa versicolor*, Meissn.). A vigorous perennial climber, 15–20 ft. high: lvs. with a cordate base, 3-lobed, the middle lobe longest and narrowed below: fls. ½–¾ in. wide, opening rich crimson, soon fading to pale yellow. July–Sept. Mex. Gn. 30, pp. 436, 437; 39:144. R.H. 1887, p. 19. G.C. II. 26:684, 685. P.M. 16:100. V. 10:34, 35. B.R. 28:24. J.F. 4:400.

3302. *Quamoclit coccinea*. (×½)

—Distinguished from all other ipomœas by its bag-shaped corolla and scorpioid infl. It is a very free bloomer, and deservedly popular. H. D. HOUSE.

QUÁSSIA (from an aboriginal name). *Simarubaceæ*. Trees, sometimes cultivated in the warmhouse.

Leaves alternate, pinnate; lfts. alternate, entire, coriaceous; panicles axillary and terminal, elongated,

3303. *Quamoclit coccinea* var. *hederifolia*. ($\times \frac{1}{2}$)

branched; fls. subcymose-dioecious; calyx small, 5-lobed; petals 5; stamens 10 in the male, rudimentary in the female fls.; ovary sunken in the disk, deeply 5-parted; fr. 1-5 spreading sessile drupes.—About 5 species, Trop. Amer. and Trop. Afr.

amara, Linn. Shrubby tree: lvs. opposite, odd-pinnate, dark green with bright pink veins; lfts. 5, elliptical-oblong, pointed, entire, tapering toward the base, subsessile at the petiolar strictures; petiole articulate, winged; fls. crimson, in racemes; corollas never fully expanded, the petals having a spiral twist and curling round one, another; drupes biglandular ovoid, black with a pale spot at the base. Trop. Amer. B.M. 497.—It furnishes the bitter quassia wood and its medicinal extract is used as a tonic. Now cult. in the tropics of both hemispheres.

F. TRACY HUBBARD.

QUEEN OF THE MEADOWS: *Filipendula Ulmaria*. Q. of the Prairie: *Filipendula rubra*.

QUEKÉTTIA (in honor of E. J. Quekett). *Orchidaceæ*. Small epiphytic plants: lvs. terete, fleshy; scape filiform, branched; fls. small; sepals and petals similar, linear; lip erect from foot of column, about as long as sepals, entire, hollowed at base; column erect, with 2 recurved appendages at apex; anther terminal, incumbent; pollinia 2, waxy, ovoid, upon linear stalks.—About 6 species known, all Brazilian. Related to *Ada*; little known horticulturally. GEORGE V. NASH.

QUÉRCUS (ancient Latin name). *Fagaceæ*. OAK. Ornamental trees, rarely shrubs, grown chiefly for their handsome foliage and interesting habit; many species are important timber trees. See *Oak*.

Deciduous or evergreen trees, rarely shrubby; winter buds with usually many imbricate scales; lvs. alternate, short-petioled, with deciduous stipules, pinnately, serrate, lobed or pinnatifid, rarely entire; fls. monœcious; the staminate in slender, pendulous

catkins with 4-7-parted calyx and 4-12, usually 6, stamens; pistillate in 1- to many-fl. spikes in the axils of the young lvs., each fl. consisting of an incompletely 3-, or rarely 4-5-celled ovary, surrounded by imbricate bracts; style short or elongated, dilated above and stigmatic on the inner face: fr. a 1-seeded subglobose to oblong nut, surrounded at the base or sometimes almost inclosed by a cup-like involucre.—More than 200 species are known, distributed through the colder and temperate regions of the northern hemisphere and in the mountains of the tropics. The numerous species are usually divided into 3 subgenera. The species of the subgenus *Cyclobalanopsis* which has the scales of the cup connate into concentric rings are all Asiatic. The American species belong to *Lepidobalanus* (*balanus* is Greek for acorn) and to *Erythrobalanus*. In the former, comprising the white oak tribe, the acorns mature the first year (Fig. 3304). In the latter, comprising the black oaks, the acorns mature the second year (Fig. 3305). Besides the 200 species, about 40 hybrids have been recorded. *Pasania*, often included under *Quercus*, is now usually considered a distinct genus, which see. The latest monograph of the whole genus is by A. DeCandolle in "Prodromus," vol. 16, 2, pp. 1-108 (1864-1868). Important illustrated works on American oaks are A. Michaux, "Histoire des Chênes de l'Amerique" (1801), with 36 plates; Kellogg and Greene, "Illustrations of West American Oaks" (1889), with 37 plates; Sargent, "Silva of North America," vol. 8 (1895), with 82 plates, and Liebmans, "Chênes de l'Amerique Tropicale" (1869), with 47 plates. Most of the European and west Asian oaks are figured in Kotschy "Eichen Europas und des Orients" (1862), with 40 colored plates. For comparative illustrations of lvs. see M.D. 1900, p. 32; R.B. 27, p. 61; G.W. 7, pp. 570, 571, 573; for those of frs. see M.D. 1900, p. 40; R.B. 27, p. 109.

The oaks are mostly trees, often tall with massive trunk and stout spreading limbs, with medium-sized, short-petioled leaves, usually more or less lobed, dentate or serrate, rarely entire, with inconspicuous flowers, the staminate ones in slender pendulous catkins and with fruits or "acorns" consisting of a globular to oblong nut inclosed at the base only, rarely wholly or nearly wholly, by a cup-like involucre. The oaks comprise some of the most important forest trees of the northern hemisphere.

3304. Annual-fruited oak—*Quercus alba*. The mature acorn is borne on the wood of the season. ($\times \frac{1}{4}$)

The wood of most species is strong, tough, hard and durable, and highly valued for many purposes, especially ship-building, construction, for furniture, and in the manufacture of wagons, tools and many other articles. The bark of some species, in America that of *Q. velutina* and *Q. prinus*, is used for tanning leather. Cork is obtained from the bark of *Q. suber* and *Q. occidentalis* in southern Europe. The bark of a few species has also been employed in medicine. The

acorns of several species are edible, in America especially those of *Q. prinus*, *Q. emoryi* and *Q. lobata*; in Europe those of *Q. ilex* var. *ballota* and *Q. agrifolia*; in Japan those of *Q. glauca*; in many European countries the acorns of all species are an important food for hogs. In eastern Asia a silkworm feeds on the leaves of different species. A parasitic insect living on *Q. coccifera* in

southern Europe and northern Africa yields a scarlet dye. Galls caused by the puncture of certain insects are used for tanning and dyeing and are now chiefly obtained from *Q. Ilex* var. *infectoria* in western Asia. Some of the above-mentioned species are described only in the supplementary list, page 2890.

The deciduous species are mostly hardy North, while of the evergreen ones none seems to be hardy farther north than Washington, D.C.; some half-evergreen oaks, as *Q. Pseudoturneri* and *Q. macedonica*, will probably prove hardy in the vicinity of New York.

Most of the oaks are stately trees of noble and majestic habit with stout, wide-spreading branches; some, as *Q. alba*, *Q. Garryana*, *Q. virginiana*, and *Q. chrysolepis*, often cover a space more than 100 feet in diameter; others, as *Q. macrocarpa*, *Q. montana* and *Q. velutina*, have a more oval, round-topped head, while *Q. palustris* and *Q. imbricaria* form symmetrical broad pyramids. A very few hardy species are shrubs, generally called scrub oaks, as *Q. prinoides* and *Q. ilicifolia*. Oaks rank among our

3305. Biennial-fruited oak. — *Quercus velutina*. The mature acorn is borne on two-year-old wood: that is, the acorn does not mature until it is two years old. ($\times \frac{1}{4}$)

most valuable park and avenue trees, and are as beautiful when grown as single trees as they are when grouped together and forming groves and woods. As avenue trees, *Q. palustris*, *Q. rubra*, *Q. coccinea*, *Q. imbricaria* and *Q. Phellos* are among the best, the last-named when medium-sized trees are desired; in the southern states, *Q. laurifolia*, *Q. nigra*, and the evergreen *Q. virginiana* are preferred. The shrubby species, like *Q. prinoides* and *Q. ilicifolia*, may be used for covering rocky hillsides and dry ridges.

Oak leaves are always beautiful. They have many shades of green; especially attractive are some with leaves of contrasting colors, the under side being silvery white, the upper one dark green, as in *Q. Muhlenbergii*, *Q. macrocarpa*, *Q. Prinus*, and some foreign evergreen species. In many oaks the leaves show a handsome pink or crimson color when unfolding, and some species assume brilliant autumnal tints. Especially beautiful in autumn are *Q. coccinea* and *Q. palustris*, with the foliage turning brilliant scarlet; *Q. rubra*, *Q. imbricaria*, and *Q. Prinus*, which turn bright or dark red; *Q. alba*, violet or vinous purple; *Q. lyrata*, scarlet or orange; *Q. Phellos*, pale yellow; *Q. montana*, orange or orange-brown; *Q. falcata* and *Q. ilicifolia*, orange-brown or yellow; *Q. stellata* and *Q. nigra*, brown or dull orange. Some of the foreign species, like *Q. sessiliflora* and also *Q. Robur*, *Q. Cerris*, *Q. lanuginosa*, *Q. glandulifera*, and others, retain the green color until late in fall. Besides our native evergreen species, the Japanese *Q. acuta*, *Q. myrsinæfolia*, and *Q. glauca* are among the best evergreen oaks for cultivation in the South; the European *Q. Ilex* and *Q. Suber* are also handsome evergreen trees.

Generally the oaks grow best in a moderately moist rich soil, including heavy clay; some, as *Q. bicolor*, *Q. nigra*, *Q. alba*, *Q. Phellos*, *Q. falcata*, and *Q. virginiana*, prefer moister situations and grow naturally in low and often even in swampy ground; while others,

especially the red oaks, like *Q. rubra*, *Q. coccinea*, *Q. imbricaria*, *Q. marilandica*, *Q. montana*, and *Q. stellata*, grow well in drier, rocky or sandy soil, and the scrub oaks on dry and barren soil. The black and red oaks, especially the pin oak, are usually easily transplanted and large trees are moved successfully, while the white oaks are more particular and only younger nursery-grown trees can be safely transplanted.

Oaks are propagated usually by seeds sown immediately after gathering in fall; this is especially necessary with *Q. alba*, *Q. virginiana*, and some other white oaks which sprout as soon as they are ripe; but only the root is produced in fall, while the stem does not appear until the following spring. The seeds of red and black oaks, and also of *Q. Robur*, if not sown at once should be stratified and sown early in spring. Acorns should be packed in earth, moss, or sawdust when shipped for a great distance. Varieties are usually grafted on potted stock in the greenhouse in early spring or sometimes in August. As a stock *Q. Robur* is preferred, but *Q. rubra*, *Q. velutina*, and *Q. montana* are also employed. It is probably safer to graft varieties of white and of red oak each on stock of the same group. The evergreen species are sometimes increased by layers and also by cuttings.

KEY TO THE SPECIES.

- A. Scales of the cupula distinct, imbricate.
- B. Walls of nut tomentose on the inner surface: lvs. lobed, with bristle-tipped teeth and lobes or entire, bristly-pointed, but not serrate and not evergreen: fr. ripening the second year: bark dark-colored, not scaly. BLACK OAKS. (*Erythrobalanus*.)
- C. Lvs. pinnatifid, slender-stalked.
- D. Lobes of lvs. usually toothed: under side glabrous or rarely pubescent.

- E. Longest lobe of the lf. about equaling the breadth of the broadish middle portion of the lf. 1. *rubra*
- EE. Longest lobes of the lf. 2-6 times as long as the narrow middle portion.
- F. Upper scales of cup closely appressed: lvs. glabrous: winter buds glabrous or puberulous.
- G. Cup brown, glabrous or puberulous and glabrate.
- H. Shape of cup flat, saucer-like: lvs. usually cuneate at base..... 2. *palustris*
- HH. Shape of cup hemispherical or turbinate: lvs. usually nearly truncate..... 3. *coccinea*
- GG. Cup grayish or pale brown, pubescent.
- H. Acorn about $\frac{3}{4}$ in. thick: cup $\frac{3}{4}$ -1 in. broad..... 4. *Schneckii*
- HH. Acorn about $\frac{1}{2}$ in. thick: cup $\frac{1}{2}$ - $\frac{3}{4}$ in. broad..... 5. *ellipsoidalis*
- FF. Upper scales of cup loosely imbricate.
- G. Winter buds puberulous or glabrous: acorn 1- $1\frac{1}{2}$ in. long..... 6. *Kelloggii*
- GG. Winter buds tomentose: acorn $\frac{1}{2}$ - $\frac{3}{4}$ in. long... 7. *velutina*
- DD. Lobes of lvs. entire or few-toothed: under side whitish or grayish tomentose.
- E. Plant a tree: lobes elongated, usually falcate.
- F. Under side of lvs. tawny or grayish pubescent..... 8. *falcata*
- FF. Under side of lvs. white-tomentose..... 9. *pagodæfolia*
- EE. Plant a shrub: lobes broadly triangular..... 10. *ilicifolia*
- CC. Lvs. obovate, 3-5-lobed at the apex or almost entire, short-stalked..
- D. Shape of lvs. obovate-spatulate: lvs. glabrous..... 11. *nigra*
- DD. Shape of lvs. broadly obovate: lvs. rusty pubescent beneath 12. *marilandica*
- CCC. Lvs. oblong or linear-oblong, entire, rarely remotely toothed.
- D. Under side of lvs. glabrous.
- E. Lvs. lanceolate or linear-oblong, light green above, acute..... 13. *Phellos*
- EE. Lvs. oblong, dark green above. 14. *laurifolia*
- DD. Under side of lvs. brownish pubescent..... 15. *imbricaria*
- BB. Walls of nut glabrous on the inner surface (except Nos. 41, 42): lvs. sinuately lobed or toothed, not bristle-tipped, rarely serrate with bristly teeth; the evergreen lvs. sometimes entire: fr. ripening the first year (except Nos. 16, 37, 41, 42).
- WHITE OAKS. (*Lepidobalanus*.)
- C. Foliage deciduous.
- D. Lvs. sinuately dentate or serrate.
- E. Scales of cup linear or lanceolate, spreading and recurved.
- F. Margin of lvs. serrate: lvs. white-tomentose beneath. 16. *variabilis*
- FF. Margin of lvs. obtusely dentate, pubescent beneath..... 17. *dentata*
- EE. Scales of cup appressed, imbricate.
- F. Petioles very short: lvs. usually auriculate at base, glabrous or nearly so beneath 18. *mongolica*
- FF. Petioles rather slender: lvs. cuneate or rounded at the base.
- G. Lobes of lvs. acute or acutish (sometimes obtusish in No. 20).
- H. Fr. peduncled: lvs. silky-pubescent beneath..... 19. *glandulifera*
- HH. Fr. sessile or nearly so: lvs. tomentulose beneath.
- I. Teeth 7-15 on each side of lf.: trees.
- J. Petiole stout, $\frac{1}{4}$ - $\frac{3}{4}$ in. long; pairs of veins 10-15; base of lf. often rounded..... 20. *aliena*
- JJ. Petiole slender, $\frac{1}{2}$ -1 in. long; pairs of veins 7-13; base of lf. cuneate..... 21. *Muhlenbergii*
- II. Teeth 3-7 on each side: shrub..... 22. *prinoides*
- GG. Lobes of lvs. rounded.
- H. Peduncle of fr. short or almost none.
- I. Under side of lvs. whitish or grayish tomentose..... 23. *Prinus*
- II. Under side of lvs. pubescent or nearly glabrous, pale greenish..... 24. *montana*
- HH. Peduncle much longer than petiole: lvs. tomentulose beneath. 25. *bicolor*
- DD. Lvs. pinnately lobed.
- E. Bark separating in thin scales, light gray or light brown. American species.
- F. Under side of lvs. pubescent or tomentose.
- G. Length of lvs. 5-8 in.: lvs. lyrate-pinnatifid.
- H. Cup fringed by awned scales..... 26. *macrocarpa*
- HH. Cup not fringed.
- I. Fr. peduncled: lvs. white-tomentose beneath..... 27. *lyrata*
- II. Fr. nearly sessile: lvs. pubescent beneath 28. *stellata*
- GG. Length of lvs. 2-6 in.
- H. Upper surface of lvs. glabrous and lustrous..... 29. *Garryana*
- HH. Upper surface of lvs. pubescent and dull: acorn elongated, to $2\frac{1}{4}$ in. long..... 30. *lobata*
- FF. Under side of lvs. glabrous. 31. *alba*
- EE. Bark furrowed and ridged, not scaly, usually dark brown or dark gray. European species.
- F. Cup with imbricate, appressed scales.
- G. Lvs. glabrous below.
- H. Petioles shorter than peduncles..... 32. *Robur*
- HH. Petioles longer than peduncles..... 33. *sessiliflora*
- GG. Lvs. pubescent below.
- H. Scales of cup small, closely appressed: lvs. usually lobed..... 34. *lanuginosa*
- HH. Scales oblong to lanceolate, loosely appressed: lvs. usually pinnatifid.
- I. Petiole $\frac{1}{4}$ - $\frac{3}{4}$ in. long: fr. nearly sessile..... 35. *Toza*
- II. Petiole short: fr. stalked..... 36. *conferta*

- FF. Cup with elongated, spreading and recurved scales... 37. *Cerris*
 CC. Foliage evergreen, dentate or entire.
 D. Lvs. whitish, tomentose or tomentulose beneath; fr. ripening the first year.
 E. Margin of lvs. dentate, rarely entire.
 F. Bark of trunk corky..... 38. *Suber*
 FF. Bark of trunk smooth..... 39. *Ilex*
 EE. Margin of lvs. entire, shape elliptic to oblong..... 40. *virginiana*
 DD. Lvs. finally glabrous beneath.
 E. Under side of lvs. fulvous-tomentose during the first year..... 41. *chrysolepis*
 EE. Under side of lvs. glabrous or stellate-pubescent at first... 42. *agrifolia*
 AA. Scales of cup connate into concentric rings; lvs. evergreen. (*Cyclobalanopsis*.)
 B. Lvs. toothed, glaucous or glaucescent beneath.
 C. Under side of lvs. silky, at least while young..... 43. *glauca*
 CC. Under side of lvs. glabrous..... 44. *myrsinaefolia*
 BB. Lvs. entire, dull green beneath..... 45. *acuta*

Subgenus ERYTHROBALANUS. Black Oaks.

1. *rubra*, Linn. Fig. 3306. Tree, to 80, occasionally 150 ft., with stout spreading branches forming a broad, round-topped, symmetrical head: lvs. divided about half way to the middle by wide sinuses into 7-9 triangular-ovate or ovate-oblong lobes, dull green above, light green and pubescent at first beneath, at length glabrous, 5-9 in. long; fr. short-stalked; acorn ovoid, 1 in. long, embraced only at the base by the $\frac{3}{4}$ -1-in.-broad cup. Nova Scotia to Fla., west to Minn. and Texas. S.S. 8:409, 410. Em. 1:168. F.S. 17:1812, 1813. H.W. 2, p. 84.—Beautiful oak of rapid growth, growing into a large majestic tree, with usually broad

3306. Leaves and acorns of various oaks. 1. *Q. Phellos*; 2. *Q. alba*; 3. *Q. velutina*; 4. *Q. rubra*; 5. *Q. macrocarpa*; 6. *Q. macrocarpa*; 7. *Q. bicolor*.

round head, the foliage turning dark red in fall. Hybrids are known with the two following species, with *Q. velutina*, *Q. falcata*, *Q. Phellos* and *Q. imbricaria*. Var. *ambigua*, Fern. (*Q. ambigua*, Michx. f., not HBK. *Q. borealis*, Michx. f. *Q. coccinea* var. *ambigua*, Gray). Cups deeper and somewhat turbinate; acorn usually smaller. The northern form. See also note under No. 8.

2. *palustris*, Linn. PIN OAK. Fig. 3307. Tree, to 80, occasionally 120 ft., with rather short spreading branches, forming a symmetrical pyramidal head, becoming irregular and oblong in older trees: lvs. deeply pinnatifid, sometimes almost to the midrib; lobes 5-7, oblong or oblong-lanceolate, toothed, separated by wide sinuses, bright green above, light green

3307. *Quercus palustris* (on the left) and *Q. Phellos*. ($\times \frac{1}{4}$)

beneath, with axillary tufts of hairs, 3-5 in. long; fr. short-stalked; acorn subglobose or ovoid, $\frac{1}{8}$ - $\frac{1}{2}$ in. long, embraced about one-third or more by the cup. Mass., to Del., west to Wis. and Ark. S.S. 8:422, 423. Em. 1:167. A.G. 17:213. Gng. 3:129. Mn. 2:155; 6:27. F.E. 28:223. G.W. 5, p. 13.—Handsome trees, especially when young; often used for avenues; grows rapidly and prefers somewhat moist soil; foliage bright red in autumn. The tree is fibre-rooted and transplants well. Hybrids of this with the preceding species and with *Q. Phellos* have been observed in cult.

3. *coccinea*, Muench. SCARLET OAK. Figs. 3308, 3309. Tree, to 80 ft., with gradually spreading branches forming a round-topped rather open head: lvs. deeply divided by wide sinuses into 7-9 rather narrow, oblong or lanceolate, few-toothed lobes, bright green and glossy above, light green and glabrous beneath, 4-8 in. long; fr. short-stalked, ovoid to oblong-ovate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, embraced about one-half by the almost glabrous cup. Maine to Fla., west to Minn. and Mo. S.S. 8:412, 413. Em. 1:163.—Especially valuable for its brilliant scarlet fall coloring; grows well in dryish situations. Hybrids of this species with *Q. rubra* and *Q. velutina* have been found.

4. *Schnéckii*, Brit. (*Q. texana*, Sarg., in part, not Buckl.). Fig. 3310. Tree, attaining 200 ft., with an oblong open head: lvs. almost like those of *Q. coccinea*, with axillary tufts of ferruginous hairs beneath, 3-8 in. long; fr. ovoid, $\frac{1}{2}$ -1 in. long, embraced about one-third by the deeply saucer-shaped cup. Ind. and Iowa to Texas and Fla. S.S. 8:411. G.F. 7:515, 517 (adapted in Fig. 3310).—Tall tree: much like *Q. coccinea* in foliage and like *Q. rubra* in fruit, but the cup somewhat deeper and smaller and pale grayish tomentose.—The *Q. texana*, Buckl., is a small tree of S. and W. Texas, with smaller, 2-4-in.-long, less deeply lobed lvs. and oblong nuts about $\frac{1}{2}$ in. long, with a hemispherical cup. B.T. 292. Probably not in cult.

5. *ellipsoidalis*, E. J. Hill. YELLOW OAK, or BLACK OAK. Tree, to 70 ft. with ascending branches forming an oblong head: bark gray, close and smooth, yellowish within: lvs. oval in outline, truncate or broadly cuneate at the base, with 5-7 oblong lobes coarsely toothed at the summit, glabrous, lustrous and bright green above, paler beneath with axillary tufts of hairs, 3-5 in. long; fr. short-stalked or nearly sessile; acorn ellipsoid to subglobose, $\frac{1}{8}$ - $\frac{3}{4}$ in. long, inclosed about one-third or

one-half by the turbinate or deeply saucer-shaped cup gradually narrowed at the base, with closely appressed, brown-pubescent scales. S. Mich. to Man. and Iowa. S.S. 14:771.

6. *Kéloggii*, Newb. (*Q. californica*, Coop.). CALIFORNIAN BLACK OAK. Fig. 3311. Tree, occasionally to

3308. Leaves of *Quercus coccinea* ($\times \frac{1}{2}$). No. 3.

100 ft., with stout spreading branches forming an open, round-topped head: lvs. divided about to the middle by wide sinuses into usually 7 oblong, toothed lobes, pubescent when young, at length glabrous and glossy above, yellowish green and glabrous or floccose beneath, 3-6 in. long: fr. short-stalked; acorn ovoid or oblong, mostly rounded at the top, 1-1½ in. long, embraced about one-third or one-half by the deep hemispherical glabrous cup. Ore. to Calif. S.S. 8:416. G.F. 9:145.

7. *velutina*, Lam. (*Q. tinctoria*, Bartram). BLACK OAK. YELLOW-BARK OAK. Figs. 3305, 3306, 3309. Tree, to 80, sometimes to 150 ft., with rather slender branches, spreading gradually into a narrow, open head: bark very dark brown, inner bark orange: lvs. pinnatifid to or beyond the middle, with 7-9 broad toothed lobes, dark and dull green above, brownish pubescent beneath at first, glabrous at length, except in the axils of the veins, 4-10 in. long: fr. short-stalked; acorn ovoid, ½-1 in. long, embraced about one-half by the hemispherical densely pubescent cup. Maine to Fla., west to Minn. and Texas. S.S. 8:414, 415. Em. 1:160. G.F. 5:55. —This species hybridizes with *Q. coccinea*, *Q. rubra*, *Q. imbricaria* and *Q. Phellos* (*Q. heterophylla*, Michx.).

3309. Acorns of *Quercus coccinea* (on left) and *Quercus velutina*. (Natural size.) Nos. 3 and 7.

8. *falcata*, Michx. (*Q. digitata*, Sudw. *Q. cuneata*, Auth., not Wang.). SPANISH OAK. Tree, to 70, rarely to 100 ft., with stout spreading branches forming an open, round-topped head: lvs. deeply pinnatifid, with 5-7 entire, acute and often falcate lobes gradually narrowed from a broad base and spreading at nearly right angles, separated by broad sinuses, drooping, dark

green and glabrous above, tawny or grayish pubescent beneath, 3-8 in. long: fr. short-stalked; acorn subglobose, ½ in. high, embraced one-half by the turbinate cup. N. J. to Fla., west to Mo. and Texas. S.S. 8:420. G.F. 8:104. F.E. 29:943. —Handsome, with peculiarly distinct foliage, but not quite hardy N. It appears that the original description of *Q. rubra*, Linn., applies to the Spanish oak (see Sargent in *Rhodora* 17:39); therefore, under a strict application of the rule of priority, *Q. falcata*, Michx., ought to be called *Q. rubra* and the tree heretofore known as *Q. rubra* ought to be known as *Q. borealis*, if var. *ambigua* is not considered specifically distinct; otherwise it ought to receive a new name. The name *Q. borealis* applies more strictly to the northern form (*Q. rubra* var. *ambigua*), while the more southern form becomes *Q. borealis* var. *maxima*, Sarg.

9. *pagodæfolia*, Ashe (*Q. falcata* var. *pagodæfolia*, Ell.). SWAMP SPANISH OAK. Tall tree, sometimes 120 ft. high, with wide-spreading branches forming a broad open head, but narrow in the forest; branchlets tomentose: lvs. deeply pinnatifid, with 5-11 entire, acute, spreading lobes narrowed from a broad base and often falcate, dark green and lustrous above, white-tomentose beneath, 5-8 in. long: fr. short-stalked or nearly sessile; acorn ovate to subglobose, little over ½ in. across, inclosed about one-half by the turbinate cup; scales loosely imbricate, pubescent except on the margin. Va. to Fla., west to S. Ill. and Ark. S.S. 14:772. — Handsome and valuable timber tree; about as hardy as the preceding species.

10. *ilicifolia*, Wang. (*Q. Bânisteri*, Michx. *Q. nana*, Sarg.). BEAR or SCRUB OAK. Intricately branched, spreading shrub to 10 ft. high, rarely small tree to 20 ft.: lvs. pinnately lobed, with usually 2 broad triangular lobes on each side, dark green and glabrous above,

3310. *Quercus Schneekii*. No. 4.

whitish tomentulose beneath, 2-5 in. long: fr. short-stalked; acorn globose-ovoid, ½ in. or less high, embraced about one-half by the saucer-shaped cup. Maine to Va., west to Ohio and Ky. S.S. 8:424. Em. 1:170. —Growing naturally on dry rocky soil and forming dense thickets; it may be used for covering barren rocky ridges and hillsides. Hybrids with *Q. coccinea*, *Q. velutina*, *Q. marilandica*, and *Q. Phellos* are known.

11. *nigra*, Linn. (*Q. aquatica*, Walt. *Q. uliginosa*, Wang.). WATER OAK. Tree, to 80 ft., with rather

slender branches forming a conical, round-topped head: lvs. obovate, 3-lobed at the apex or sometimes entire, rarely pinnatifid above the middle, dull bluish green above, paler beneath, soon glabrous except axillary tufts of brown hairs beneath, $1\frac{1}{2}$ -3 in. long: fr. short-stalked; acorn globose-ovoid, $\frac{1}{2}$ - $\frac{2}{3}$ in. high, embraced one-fourth to one-third by the saucer-shaped cup. Del. to Fla., west to Ky. and Texas. S.S. 8:428.—Of rapid growth and easily transplanted; often planted as avenue tree in the S., but not quite hardy N. Usually called *Q. aquatica*.

3311. *Quercus Kelloggii*. ($\times \frac{1}{2}$)

12. *marilandica*, Muench (*Q. nigra*, Wang. *Q. ferruginea*, Michx.). BLACK JACK. JACK OAK. Tree, to 30, sometimes to 50 ft., with short spreading branches forming a narrow, round-topped or often irregular head: lvs. obovate, 3-5 lobed at the broad apex, with broad, entire or sparingly toothed lobes, glabrous and dark green above, at length glabrous and yellowish green beneath, brownish tomentose at first: fr. short-stalked; acorn ovoid-oblong, $\frac{3}{4}$ in. high, embraced one-third to two-thirds by the turbinate cup. N. Y. to Fla., west to Neb. and Texas. S.S. 8:426, 427.—There are hybrids with *Q. ilicifolia*, *Q. Phellos*, and *Q. imbricaria*. Handsome tree, with large glossy foliage; hardy N. Better known as *Q. nigra*, but this name really belongs to the preceding species.

13. *Phellos*, Linn. WILLOW OAK. Figs. 3306, 3307. Tree, to 50 ft., sometimes becoming 80 ft., with rather slender branches forming a conical, round-topped head: lvs. short-petioled, linear-oblong, bright green and glossy above, pubescent below when young, glabrous and light green at length, 2-4 in. long: frs. almost sessile, acorn subglobose, $\frac{1}{2}$ - $\frac{1}{2}$ in. high, embraced about one-fourth by the saucer-shaped cup. N. Y. to Fla., west to Mo. and Texas. S.S. 8:435. Gt. 29, p. 221. A.G. 17:195. F.E. 18:592 (pl. 87). R.H. 1898, p. 149.—Hybrids have been recorded with *Q. palustris*, *Q. rubra*, *Q. velutina*, *Q. ilicifolia* and *Q. marilandica*. Beautiful hardy medium-sized tree with handsome foliage turning pale yellow in fall; prefers moist or almost swampy soil.

14. *laurifolia*, Michx. LAUREL OAK. Tree, to 60, occasionally to 100 ft., with comparatively slender branches forming a dense, round-topped head: lvs. oblong or oblong-obovate, sometimes slightly lobed, acute or rarely obtusish, dark green and shining above, light green and puberulous at first, glabrous at length below, 2-6 in. long: fr. short-stalked; acorn ovoid or subglobose, about $\frac{1}{2}$ in. long, embraced one-fourth by the saucer-shaped cup. Va. to Fla. and La. S.S. 8:429, 430. F.E. 16:396 (pl. 62).—

3312. *Quercus lobata*. ($\times \frac{1}{2}$)

Handsome tree with almost half-evergreen glossy foliage, often planted as avenue tree in the southern and Gulf States; a particularly good form of this species is in the trade as "Darlington oak." Not hardy N.

15. *imbricaria*, Michx. SHINGLE OAK. Tree, to 60, rarely to 100 ft., with slender and somewhat pendulous branches, of pyramidal habit in its youth, round-topped when old: lvs. oblong or oblong-lanceolate, dark green and glabrous above, grayish tomentulose beneath, 3-7 in. long: fr. short-stalked; acorn subglobose, $\frac{1}{2}$ in. long, embraced one-third to one-half by the turbinate cup. Pa. to Ga., west to Neb. and Ark. S.S. 8:432. A.G. 17:195. Mn. 6:91.—Beautiful oak of symmetrical habit with handsome glossy foliage, turning russet-red in fall. There are hybrids of this species; with *Q. marilandica*, *Q. velutina*, *Q. rubra*, and *Q. palustris*, of which the last is in the trade as *Q. palustri-imbricaria*, Engelm.: it has oblong-lanceolate lvs. entire or coarsely

toothed, with bristly teeth, soon glabrous, 4-6 in. long: cup turbinate.

Subgenus LEPIDOBALANUS. White Oaks.

16. *variabilis*, Blume (*Q. chinensis*, Bunge, not Abel. *Q. Bungeana*, Forbes. *Q. serrata*, Carruth., not Thunb.). Tree, to 80 ft.: lvs. slender-petioled, oblong to oblong-lanceolate, acuminate, crenately serrate, with bristle-like teeth, dark green and glabrous above, whitish tomentulose below, $3\frac{1}{2}$ -6 in. long: fr. almost sessile; acorn subglobose, not much exceeding the large cup; scales thick, lanceolate, recurved. N. China, Japan. S.I.F. 1:28.—Handsome tree with distinct foliage almost like that of *Castanea crenata*; has proved hardy in Mass. and W. N. Y.

17. *dentata*, Thunb. (*Q. Daimio*, Hort. *Q. obovata*, Bunge). Tree, to 80 ft., with broad, round-topped head: lvs. short-petioled, obovate, sinuately toothed, with 3-6 rounded broad teeth on each side, dark green

3313. White oak.—*Quercus alba* ($\times \frac{1}{4}$). No. 31.

and usually glabrous above at length, light green and pubescent beneath, firm and leathery, to 12 in. long: fr. almost sessile; acorn ovate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long, embraced one-half by the large cup; scales lanceolate, thin, spreading and recurved. Japan, W. China. S.I.F. 1:27. F.E. 14:542 (pl. 29).—Remarkable for its large lvs., on young plants to 1 ft. long and 8 in. broad; hardy N. Var. *pinnatifida*, Matsum. (*Q. pinnatifida*, Franch. & Sav.). Lvs. divided almost to the midrib into linear lobes with crisp irregular margins; interesting form.

18. *mongolica*, Fisch. Tree, to 100 ft.: branchlets glabrous: lvs. on very short petioles less than $\frac{1}{4}$ in. long, obovate to obovate-oblong, obtuse at the apex, narrowed toward the rounded or auriculate base, coarsely toothed or sinuately lobed, with short and broad usually obtuse or obtusish teeth, dark green above and glabrous, paler green and glabrous beneath or pilose on the veins only, 4-8 in. long: fr. several or solitary on a short stalk or nearly sessile; acorn ovoid or ellipsoid, about $\frac{1}{4}$ in. long, embraced about one-third by the cup which is grayish tomentulose with thickened tuberculate scales, thinner and acuminate at the slightly fringed margin. E. Siberia, N. China, Korea, N. Japan. Var. *grosseserrata*, Rehd. & Wilson (*Q. grosseserrata*, Blume. *Q. crispula*, Blume). Lvs. somewhat smaller, usually acutish at the apex with acute or acutish sometimes denticulate teeth: cup with thin closely appressed scales, not fringed at the margin. Japan. S.I.F. 1:27.—Some Japanese botanists distinguish *Q. crispula* as a species by the hemispherical cup inclosing the acorn about one-half from *Q. grosseserrata* which has a saucer-shaped cup inclosing the acorn one-fourth or one-third, but many specimens are intermediate in this character, and, as the lvs. of the two forms are exactly alike, it seems hardly possible to distinguish these two

forms as varieties. Var. *grosseserrata* has proved perfectly hardy at the Arnold Arboretum and forms handsome trees of vigorous growth.

19. *glandulifera*, Blume. Tree, to 40 ft., rarely to 70 ft., shrubby in cult.: lvs. cuneate or rounded at the base, oblong-obovate to oblanceolate, acute with 7-12

3314. Staminate catkins.—*Quercus Robur* ($\times \frac{1}{4}$). No. 32.

some foliage, hardy at the Arnold Arboretum. Sometimes cult. under the name *Q. dentata*. *Q. glandulifera*, Mast., is *Q. Pseudoturneri* (see suppl. list).

20. *aliëna*, Blume. Tree, to 50 ft. or more: branchlets glabrous: lvs. oblong-obovate, obtuse or acutish at the apex, rounded or broadly cuneate at the base, coarsely sinuate-dentate with broad obtuse or acutish teeth, dark yellowish green and glabrous above, whitish or grayish tomentulose beneath, with 10-15 pairs of veins, 4-8 in. long; petioles $\frac{1}{4}$ - $\frac{3}{4}$ in. long: frs. 1-3, short-stalked or nearly sessile; acorn ellipsoid to oblong, $\frac{3}{4}$ -1 in. long, embraced about one-third by the cup-shaped grayish tomentulose cup, its scales thin, acuminate. S.I.F. 1:28. Japan, Korea, Cent. China. Var. *acuteserrata*, Maxim. Lvs. usually somewhat smaller and narrower, with acute or acutish gland-tipped teeth often slightly incurved at the apex. Japan, Cent. China.—This recently intro. species has proved hardy at the Arnold Arboretum.

21. *Muhlenbergii*, Engelm. (*Q. Castanea*, Willd., not Née. *Q. acuminata*, Sarg., not Roxbg. *Q. Prinus* var. *acuminata*, Michx.). YELLOW CHESTNUT OAK. Tree, to 100 or occasionally to 160 ft., with rather short branches, forming a narrow, round-topped head: lvs. slender-stalked, oblong to oblong-lanceolate, acute or acuminate, coarsely toothed with acute, glandular-tipped teeth, dark or yellowish green above, whitish tomentulose beneath, 4-7 in. long: fr. sessile or short-peduncled; acorns ovate, $\frac{1}{4}$ - $\frac{3}{4}$ in. long, embraced about one-half by the cup. Tenn. to Va., west to Neb. and Texas. S.S. 8:377.—Beautiful tree with light gray bark and handsome foliage, glossy above and silvery white beneath.

3315. English oak.—*Quercus Robur*. (Natural size). No. 32.

22. *prinoides*, Willd. (*Q. Chincapin*, Pursh. *Q. Prinus* var. *Chincapin*, Michx.). CHINCAPIN OAK. Spreading shrub, with slender sts., usually not over 6 ft. high, rarely to 15 ft.: lvs. rather short-petioled, cuneate at the base, ovate-oblong or oblong, with 4-8 sometimes obtusish teeth on each side, bright green above,

grayish tomentulose beneath, $2\frac{1}{2}$ -5 in. long: fr. sessile, acorn oval, about $\frac{1}{2}$ in. long, embraced one-half by the cup. Maine to Ala., west to Minn. and Texas. S.S. 8:378. Em. 1:158.—Pretty shrub for covering dry and rocky ridges. In trade sometimes under the misleading name of *Q. humilis*, for which see suppl. list.

23. *Prinus*, Linn. (*Q. Prinus* var. *palustris*, Michx. *Q. Michauxii*, Nutt.). BASKET OAK. COW OAK. Tree, to 100 ft., with round-topped, rather dense head: bark light gray, scaly: lvs. obovate or obovate-oblong, acute, deeply crenulate-toothed, with obtuse, mucronulate teeth, bright green and shining above, grayish tomentulose beneath, 4-7 in. long: fr. short-peduncled; acorn ovoid, 1- $\frac{1}{2}$ in. high, embraced about one-third by the tomentose cup. Del. to Fla., west to Ind. and Texas. S.S. 8:382, 383.—The *Q. Prinus* of most recent authors is the following species. One of the most beautiful of the chestnut oaks; prefers moist soil.

24. *montana*, Willd. (*Q. Prinus* var. *monticola*, Michx. *Q. Prinus*, Engelm., not Linn.). CHESTNUT OAK. ROCK CHESTNUT OAK. Fig. 3306. Tree, to 70, or occasionally to 100 ft., with broad, irregular head and dark brown, ridged bark: lvs. slender-stalked, obovate to oblong-lanceolate, coarsely crenulate-toothed, bright or yellowish green above, paler beneath, tomentulose when young, often almost glabrous at length, 5-8 in. long: fr. solitary or in pairs, on peduncles about 1 in. long; acorn ovoid, 1- $\frac{1}{2}$ in. high, embraced about one-third by the cup. Maine and Ont. to Ala. S.S. 8:375, 376. Em. 1:155 (as *Q. Castanea*) and 156. G.C. III. 14:617. G.F. 1:510.—Handsome oak, growing well in rather dry soil. A hybrid of this

3316. *Quercus Robur* var. *filicifolia* ($\times \frac{1}{4}$). No. 32.

species and *Q. Robur* is *Q. Sargentii*, Rehd., a tree of vigorous growth with handsome foliage, chiefly distinguished from *Q. montana* by the fewer lobes and the auriculate base of the lvs.

25. *bicolor*, Willd. (*Q. platanoides*, Sudw. *Q. Prinus* var. *tomentosa*, Michx. *Q. Prinus* var. *discolor*, Michx. f.). SWAMP WHITE OAK. Fig. 3306. Tree, to 70 ft., rarely to 100 ft., with narrow, round-topped, open head and light grayish brown, scaly bark: lvs. obovate to oblong-obovate, sinuately dentate, sometimes lobed half-way to the middle, dark green and dull above, whitish tomentulose beneath, 4-7 in. long: fr. solitary or in pairs, on peduncles $1\frac{1}{2}$ -4 in. long; acorn ovate-

oblong, 1-1½ in. high, embraced one-third by the cup. Que. to Ga., west to Mich. and Ark. S.S. 8:380, 381. Em. 1:153. G.F. 4:246.—It is less desirable as an ornamental tree than many other species, but the wood is valuable. By the light gray bark separating in large thin scales and the numerous small branches which appear on the larger limbs and often on the trunk, it is easily distinguished from allied species.

26. *macrocarpa*, Michx. BUR OAK. MOSSY CUP OAK. Fig. 3306. Tree, to 80, sometimes 160 ft., with large spreading branches, forming a broad, round head: bark light brown, deeply furrowed; younger branches sometimes with corky wings: lvs. obovate or oblong-obovate, lyrate-pinnatifid, with 4-10 pairs of lobes, the lower ones smaller, separated by wide and deep sinuses, the upper ones much larger, or sometimes the lvs. are only sinuately dentate above the middle, bright green and shining above, grayish or whitish tomentose beneath, 4-8 in. long: fr. sessile or short-stalked; acorn broadly ovate or ovoid, ¾-1½ in. high, embraced about one-half by the large ¾-2-in.-wide cup, with the upper scales awned and forming a fringe-like border. Nova Scotia to Pa., west to Man. and Texas. S.S. 8:371, 372. Em. 1:149. G.F. 2:500; 3:407. Mn. 2:153. Gng. 4:342. Var. *olivæformis*, Gray (*Q. olivæformis*, Michx.). Lvs. deeply pinnatifid, lobes almost all narrow and separated by wide sinuses: cup usually elongated, much higher than broad. S.S. 8:373. M.D.G. 1901:167.—The bur oak is of vigorous growth and becomes a stately tree and is of picturesque appearance in winter with its corky branches. The crown is often fan-shaped until tree is mature.

27. *lyrata*, Walt. OVERCUP OAK. SWAMP, or SWAMP POST OAK. Tree, to 100 ft., with rather small, often pendulous branches forming a symmetrical, round-topped head: lvs. obovate to obovate-oblong, deeply lyrate-pinnatifid, with 3-5 pairs of oblong or lanceolate lobes, the lower ones much smaller, separated by a wide sinus from the upper ones, dark green and shining above, whitish tomentulose beneath or sometimes light green and pubescent: fr. short-stalked; acorn globose, ½-1 in. high, almost entirely inclosed by the large scaly cup. N. J. to Fla., west to Mo. and Texas. S.S. 8:374. F.E. 17:736 (pl. 77).—Little cult.; hardy as far north as Mass.; prefers moist soil.

28. *stellata*, Wang. (*Q. obtusiloba*, Michx. *Q. minor*, Sarg.). POST OAK. Tree, to 60, rarely to 100 ft., with broad, dense, round head, and with grayish brown, deeply fissured bark: lvs. short-stalked, broadly obovate, lyrate-pinnatifid, with 2 or usually 3 pairs of lobes, the middle pair being much larger, undulate, and mostly with a lobe on the lower side, separated from the lower pair by wide, from the upper pair by narrower sinuses, dark green above, brownish tomentulose beneath, 5-8 in. long: fr. almost sessile; acorn ovoid, ¾ in. high, embraced one-third to one-half by the cup; scales lanceolate, loosely appressed. Mass. to Fla., west to Neb. and Texas. S.S. 8:368, 369. Em. 1:151.—Hardy and handsome tree with dense round head, growing naturally in rather dry, sandy or rocky soil; at the northern limit of its range, in S. Mass., it is usually shrubby.

29. *Garryana*, Douglas. OREGON OAK. Tree, to 80, rarely to 100 ft., with wide-spreading branches, sometimes shrubby: bark light gray: lvs. obovate, pinnatifid, with broad, obtuse, entire or toothed lobes, dark green above, pubescent and yellowish green or whitish below: fr. short-stalked; acorn ovoid, about 1 in. high, embraced about one-third by the saucer-shaped cup; scales usually thin. Wash. and Ore. to Calif. S.S. 8:364, 365. G.F. 7:495. F.E. 32:919.—The most important oak of the Pacific States as a timber tree.

30. *lobata*, Née (*Q. Hindsii*, Benth.). VALLEY or WEeping OAK (WHITE OAK of the Pacific States).

3317. Live oak (*Quercus virginiana*) with Spanish moss hanging from the branches. Audubon Park, New Orleans. No. 40.

Fig. 3312. Tree, to 100 ft., with great, wide-spreading limbs and slender drooping branches: lvs. oblong or obovate-oblong, with 3-5 pairs of sometimes lobed-dentate lobes, dark green and stellate-pubescent above and usually whitish tomentulose beneath, 2-4 in. long: fr. almost sessile; acorn elongated, conical, 1½-2 in. high, embraced about one-third by the cup; lower scales tuberculate, upper one subulate. Calif. S.S. 8:362. G.F. 3:611; 10:55, 202, 205. C.L.A. 1:83.—Graceful wide-spreading tree; has not been cult. successfully outside of Calif.

31. *alba*, Linn. WHITE OAK. Figs. 3304, 3306, 3313. Tree, to 100 ft., with stout spreading branches forming a broad, open head: bark light gray: lvs. obovate or oblong-obovate, narrowed at the base, with 3-8 pairs of rather narrow obtuse and sometimes toothed lobes, pubescent when young, soon glabrous, bright green above, glaucescent beneath: fr. short- or long-stalked; acorn oblong-ovate, 1 in. high, embraced about one-fourth by the shallow cup; scales closely appressed. Maine to Fla., west to Minn. and Texas. S.S. 8:356, 357. Em. 1:145. G.F. 3:91; 4:6, 7; 5:259, 450. F.E. 20:650 (pl. 110); 32:489.—The white oak is one of the noblest trees of the northern states and a beautiful park tree, where space can be allowed for its full development; the foliage assumes a beautiful deep vinous red or violet-purple color in fall. Var. *repanda*, Michx., is a form in which the lvs. have rather shallow sinuses and the frs. are usually short-stalked. Var. *pinnatifida*, Michx., has the lvs. deeply pinnatifid with narrow often deeply toothed lobes and the frs. usually

slender-stalked. S.S. 8:358. Hybrids of this species with *Q. macrocarpa*, *Q. montana*, and *Q. stellata* are known. S.S. 8:359-61. The hybrid with *Q. montana* was found in the nursery of John Saul, near Washington, D. C., and has been distributed as Saul's oak (*Q. Saulii*, Schneid.).

32. *Röbur*, Linn. (*Q. pedunculata*, Ehrh. *Q. femina*, Mill. *Q. Röbur* var. *pedunculata*, DC.). ENGLISH OAK. Figs. 3314, 3315. Tree, to 120 ft., with stout spreading branches forming a broad round-topped head: lvs. short-petioled, auriculate at the base, oblong-obovate, with 3-7 rounded lobes on each side, quite glabrous, dark green above, pale bluish green beneath, $2\frac{1}{2}$ -5 in. long: fr. 1-7 on slender peduncles; acorn ovate or ovate-oblong, about 1 in. high, embraced about one-third by the hemispherical cup. Eu., N. Afr., W. Asia. G.C. III. 24:201; 25:168. F.S.R. 2, p. 196. G.W. 13, p. 566. H.W. 2:21, pp. 53-5. F.E. 21:100 (pl. 114).—More than 40 varieties are cult. in European nurseries and collections; some of the most important are the following: Var. *Concordia*, Schneid. (*Q. pedunculata Concordia*, Kirchn.). Lvs. bright yellow. I.H. 14:537. F.E. 13:1296 (pl. 19). Var. *contorta*, Hort. A form with twisted branches and crowded lvs. of irregular shape; of slow growth. Var. *fastigiata*, Schneid. (*Q. pedunculata fastigiata*, DC.). With upright branches forming a narrow columnar head. G.C. II. 19:179; III. 41:149. G.W. 15:663. F.E. 13:416 (pl. 3) (as var. *Lucombeana*). Of the same habit are var. *fastigiata cupressoides*, Hort., with narrower lvs. Var. *fastigiata aureo-punctata* with yellowish spotted foliage. Var. *fastigiata viridis* with lvs. of darker green. Var. *heterophylla*, Rehd. (*Q. pedunculata heterophylla*, Loud. *Q. Röbur* var. *laciniata*, Schneid., var. *comp-tonizifolia*, Hort.), with narrow, elongated, slightly or crenately lobed, sometimes almost entire lvs. Var.

filicifolia, Schneid. (var. *asplenifolia*, var. *Doumetii*, Hort.). Fig. 3316. Lvs. deeply and irregularly divided often almost to the midrib in narrow linear lobes, with crisp margins. G.C. II. 14:632. I.H. 1, black fig., not numbered, opposite pl. 33. R.H. 1894, p. 17. Var. *pectinata*, Schneid. (*Q. Röbur* var. *pectinata*, Kirchn.). Lvs. regularly pinnately divided nearly to the midrib into linear lobes. Var. *péndula*, Schneid. (*Q. pedunculata péndula*, Loud.). With pendulous branches; a form with more slender and more decidedly weeping branches is var. *Dauvessiei*, Hort. Var. *purpurascens*, DC. (*Q. pedunculata purpurascens*, DC., var. *purpurea*, Loud. *Q. Röbur sanguinea*, Schneid.). With the lvs. bright purple when young, becoming almost green at length, or as in the forms distinguished as var. *atropurpurea*, Schneid., and var. *nigra*, Hort., the color is more intense and retained through the whole summer. F.S. 17:1783, 1784. There are a number of variegated forms, but of no great ornamental value; the most often cult. are: *albo-variegata*, *argenteo-marginata*, *argenteo-picta*, *aureo-variegata*, *marmorata*, *joreauensis maculata*, *tricolor*.—Hybrids between this species and the following occur occasionally in Eu. (*Q. rosacea*, Bechst. *Q. hybrida*, Bechst., not Brot.). For a hybrid with *Q. montana*, see No. 24.

3319. Acorn of live oak.—*Quercus virginiana*; often known as *Q. virens* ($\times \frac{1}{2}$). No. 40.

33. *sessiliflora*, Salisb. (*Q. sessilis*, Ehrh. *Q. Röbur* var. *sessiliflora*, DC. *Q. Röbur*, Mill., not Linn.). Similar in habit to the former, but limbs less spreading and head less broad: petioles $\frac{1}{2}$ - $\frac{3}{4}$ in. long: lvs. rounded or cuneate at base, obovate or obovate-oblong, with 5-9 rounded lobes on each side, somewhat glossy above, pale and glabrous or slightly pubescent on the midrib beneath, $2\frac{1}{2}$ -5 in. long: fr. almost sessile, usually somewhat larger than those of the preceding species. Eu., W. Asia to Persia. H.W. 2:22, pp. 65-7. F.S.R. 3, p. 117. A very distinct variety is var. *mespilifolia*, Dipp. (var. *sublobata*, Koch), with almost entire lvs. H.W. 2, p. 65. Var. *laciniata*, Koehne. Lvs. deeply lobed with narrow lobes pointing forward. Gt. 61, p. 495. Var. *aurea*, DC. Lvs. yellow while young, changing later to green. Var. *purpurea*, Dipp. Young lvs. purple, changing to dark green. Var. *Louettei*, Kirchn. With pendulous branches and narrow slightly lobed or nearly entire lvs.—*Q. sessiliflora* is less common in cult. than the preceding species; both are usually called English oak and are sometimes considered varieties of one species.

34. *lanuginosa*, Thuill. (*Q. pubescens*, Willd.). Tree, to 40 ft., but sometimes remaining shrubby: branches tomentose when young: lvs. pinnately lobed or pinnatifid, with 4-8 pairs of obtuse or acute lobes, glabrous above, pubescent or tomentose and grayish green beneath, 2-4 in. long: fr. almost sessile; acorn ovoid, $\frac{1}{2}$ -1 in. long, inclosed about one-half by the tomentose cup; scales closely appressed. Cent. and S. Eu., W. Asia. H.W. 2:23, pp. 69-71.—A very variable species, often shrubby, growing mostly on dry, rocky, and often on limestone soil; the more southern forms of it are tender. Var. *Hartwissiana*, Dipp. (*Q. Hartwissiana*, Hort.). Lvs. small, rather acutely lobed, yellowish tomentose beneath. Var. *pinnatifida*, Schneid. (*Q. pubescens* var. *pinnatifida*, A. Braun). Lvs. deeply lobed. Var. *crispata*, Beck, is similar but margin more crisp and under side more tomentose. Var. *péndula*, Jacq. (*Q. Agilops* var. *péndula* and *Q. Pseudagilops péndula*, Hort.), with pendulous branches

3318. Variation in the leaves of live oak.—*Quercus virginiana* (Nearly natural size). No. 40.

and densely tomentose lvs., resembles the following species and is supposed by some authors to be a hybrid between the two.

35. *Tôza*, Bosc (*Q. pyrenæica*, Willd. *Q. camata* and *Q. crinita*, Hort.). Tree, to 40 ft., with slender branches; branchlets yellowish tomentose: lvs. pinnatifid halfway to the middle or more, with rather narrow and acute lobes, pubescent above, yellowish or grayish tomentose beneath, 3-5 in. long: fr. short- or long-peduncled; acorn oblong, embraced one-third to one-half by the tomentose cup; scales loosely appressed, rather large. Spain, S. France. Var. *péndula*, Dipp., with pendulous branches.—Somewhat tender N.

36. *conférta*, Kit. (*Q. pannónica*, Hort. *Q. hungarica*, Hubeny). Tree, to 120 ft., with gradually spreading branches forming a round-topped, open head: bark rather light brown: lvs. very short-petioled, auriculate at the base, obovate, deeply pinnatifid, with 5-7 pairs of often toothed lobes, dark green and almost glabrous at length, pale and tomentose beneath, 4-7 in. long: fr. short-peduncled; acorn ovoid-oblong, embraced about one-third by the cup; scales rather large, loosely appressed. Italy, S. E. Eu. G.C. II. 5:85. F.E. 19:236 (pl. 99). H.W. 2:24, pp. 72, 73.—Handsome oak with dark green foliage; hardy in Mass., but seems not reliable farther north.

37. *Céris*, Linn. TURKEY OAK. Tree, to 120 ft., with rather short spreading branches forming a broad pyramidal, at length often irregular open head: lvs. oblong or obovate-oblong, pinnatifid, with 3-8 pairs of entire or few-toothed lobes, dark green and somewhat rough above, grayish pubescent or almost glabrous beneath at length: fr. short-stalked, ripening the second year; acorn oblong-ovate, to 1½ in. long, embraced about one-half by the large mossy cup. S.E. Eu. W. Asia. Mn. 3:166. Gn. 27, pp. 476, 477. H.W. 2:25, pp. 74-6. G.W. 8, p. 181. F.E. 14:1264 (pl. 41).—Handsome oak with dark green foliage and of pyramidal habit when young, but not quite hardy N. Easily recognized even in winter by the slender subulate scales surrounding and exceeding the winter buds.

3320. *Quercus chrysolepis*. (×½)

Var. *austriaca*, Loud. Lvs. longer-petioled, less deeply lobed, or almost sinuately dentate with short, acute, entire lobes. For *Q. austriaca sempervirens*, see *Q. Pseudoturneri* in suppl. list. Var. *laciniata*, Loud. Lvs. deeply pinnatifid, often almost to the midrib divided into narrow oblong acute lobes. Var. *Ambrozyana*, Aschers. & Graebn. (*Q. Ambrozyana*, Simonkai). Lvs. half-evergreen, smaller, subcoriaceous, glabrous above, with bristly teeth; stipules smaller, caducous. Hungary.—There are hybrids with *Q. Suber*, for which see *Q. Lucombeana*, in suppl. list.

38. *Süber*, Linn. CORK OAK. Evergreen tree, to 50 ft., with broad round-topped head and thick, deeply furrowed, spongy, elastic bark: lvs. ovate to oblong, rounded or subcordate at the base, remotely serrate glabrous above, whitish tomentose or sometimes glabrescent beneath, 1-3 in. long: fr. short-stalked; acorn ovate or oblong-ovate, ½-1½ in. high, embraced one-third to one-half by the cup; scales thick, usually with short and often recurved tips. S. Eu., N. Afr. H.W. 2, pp. 80, 81. G.W. 8, p. 182.—From this species cork is obtained; it is much cult. for this purpose in E. India and recently also in Calif., where it seems to thrive well. *Q. occidentalis*, Gay, differs chiefly in the fr. ripening the second year, in the less persistent lvs., the old ones mostly falling in spring, in the shorter scales of the cup and in its greater hardness; its bark is not distinguished commercially from that of the true cork oak.

39. *Îlex*, Linn. HOLLY or HOLM OAK. Evergreen tree, to 60 ft., with large, round-topped head: bark not corky: lvs. very variable, ovate to lanceolate, remotely serrate or almost entire and with revolute margin, dark green above, yellowish or whitish tomentose or sometimes glabrescent beneath, 1-3 in. long: fr. 1-3, usually peduncled; acorn ovate, embraced about one-half by the cup; scales thin, appressed, rarely slightly spreading. S. Eu. M. D.G. 1898:275. H.W. 2:25, pp. 77-79. G.M. 54:895. Gn. 65, p. 320. Var. *Ballota*, DC. (*Q. Ballota*, Desf.). Lvs. smaller, orbicular or broadly ovate; the sweet acorn

3321. *Quercus agrifolia* (×¼). No. 42.

is often gathered for food. Var. *Fördii*, Nichols. (*Q. Fördii*, Carr.). Of pyramidal habit with narrower and smaller lvs. R.H. 1861, pp. 114, 115; 1885, pp. 352, 353. Not to be confounded with *Q. Fordiana*, Hemsl., a Chinese species with chestnut-like lvs.

40. *virginiâna*, Mill. (*Q. virens*, Ait.). LIVE OAK. Figs. 3317-3319. Evergreen tree, to 50 or rarely to 70 ft., with almost horizontal limbs, forming a wide-spreading head; sometimes shrubby: lvs. elliptic or oblong, usually entire, with revolute margin, rarely with a few spiny teeth above the middle, dark green and glossy above, whitish tomentulose beneath, 1-3 in. long: fr. peduncled; acorn ovate, about 1 in. long, embraced about one-third by the cup; scales thin, appressed. Va. to Fla., west to Mex. S.S. 8:394, 395. G.F. 1:476; 5:486, 487; 6:7; 8:235. F.R. 1:643. Gng. 8:1. G.W. 9, p. 505.—One of the most beautiful of the American oaks and much planted as a shade and avenue tree in the southern states; easily transplanted and of rapid growth; also very valuable as a timber tree.

41. *chrysólepis*, Liebm. CALIFORNIA LIVE OAK. MAUL OAK. Fig. 3320. Evergreen tree, to 50, rarely to 100 ft., with wide-spreading head and often pendulous branches: lvs. short-petioled, oval to oblong-ovate, acute and spiny-toothed or entire, bluish or yellowish green above, glaucous beneath and covered with fulvous tomentum when young, 1-4 in. long: fr. short-stalked, ripening the second year; acorn ovoid, ½-1½ in. high, embraced about one-fourth by the shallow cup which is often very thick and densely fulvous-tomentose. Ore. to Calif. S.S. 8:398, 399. G.F. 5:127.—The most beautiful of the Californian oaks.

42. *agrifolia*, Née. Figs. 3321, 3322 (adapted from Pacific R. R. Report). Similar in habit to the former, sometimes shrubby: lvs. broadly oval to oblong, sinuately spiny-toothed, usually convex, dull green above, light green below, pubescent at first, 1½-3 in. long: fr. usually sessile; acorn conic-ovate, often elongated, to 1½ in. long, embraced one-fourth to one-third by the cup; scales thin, slightly puberulous. Calif. S.S. 8:403. F.S. 7, p. 138.

3322. *Quercus agrifolia*. (×½)

Subgenus CYCLOBALANOPSIS.

43. *glauca*, Thunb. (*Cyclobalanopsis glauca*, Oerst.). Evergreen tree, to 45 ft.: branchlets glabrous or nearly

so: lvs. on slender petioles $\frac{1}{2}$ –1 in. long, elliptic-oblong to ovate-oblong, acuminate, broadly cuneate or nearly rounded at the base, dentate above the middle, lustrous above, glaucous beneath and silky, at least while young, 3–5 in. long: fr. short-stalked, 1–3; cup saucer-shaped, silky-pubescent outside, with 5–7 concentric rings; nut ellipsoid, $\frac{3}{4}$ in. long. Japan. S.I.F. 1:30. I.T. 4:103.—Handsome evergreen tree, planted occasionally in Calif. and in the southeastern states.

44. *myrsinæfolia*, Blume (*Q. Vibrayana*, Franch. & Sav. *Q. bambusæfolia*, Fort., not Hance. *Cyclobalanopsis Vibrayana*, Schottky). Evergreen tree, to 50 ft.: lvs. lanceolate or oblong-lanceolate, acuminate, cuneate at the base, serrate, glaucescent and glabrous beneath from the beginning, shining green above, 3–5 in. long and $\frac{3}{4}$ –1½ in. wide: fr. in short spikes; nut oblong-ovoid, $\frac{1}{2}$ –¾ in. long, embraced about one-third by the glabrous cup consisting of about 6 concentric rings. Japan. S.I.F. 1:29.—Beautiful evergreen oak for the southern states. In the American trade confused with *Q. acuta* and in European gardens with *Q. glauca*.

45. *acuta*, Thunb. (*Q. Buérgeri*, Blume. *Cyclobalanopsis acuta*, Oerst.). Evergreen small tree: lvs. oblong-ovate to oblong-lanceolate, acuminate, rounded at the base, entire and usually undulate on the margin, glossy green above, yellowish green beneath, glabrous, only when unfolding covered with a brownish quickly disappearing floss, 3–5 in. long: fr. in nearly sessile clusters; nut ellipsoid-oblong, about ¾ in. long, embraced about one-fourth by the pubescent cup consisting of about 6 concentric rings. Japan, Korea. S.I.F. 1:32. Gn. 19, p. 285; 79, p. 388.—Handsome tree, rare in cult.

The species in the following list are not hardy North except when mentioned:

Q. acutissima, Carruthers=*Q. serrata*.—*Q. Agilops*, Linn. Evergreen tree, to 60 ft.: allied to *Q. Cerris*: lvs. lobed-dentate with acute sinuses, fulvous-tomentose at first: cup large, with spreading, flat, lanceolate scales, not much to one-half shorter than acorn. S. Italy, Greece.—*Q. Aizoon*, Koehne=*Q. Pseudoturineri*.—*Q. alnifolia*, Poech. Evergreen shrub: lvs. orbicular or oval, dentate, shining above, yellow-tomentose beneath, 1–2 in. long: cup with recurved lanceolate bracts; acorn 1½ in. long. Crete. Gn. 18, p. 486; 40, p. 95. A.G. 13:436.—*Q. aquifolioides*, Rehd. & Wilson. Evergreen shrub or tree, to 30 ft.: branchlets pubescent: lvs. subsessile, elliptic or ovate-elliptic, auriculate, spinose-dentate or entire, lustrous above, yellowish brown-tomentose beneath, 1½–3 in. long: fr. several, peduncled; cup saucer-shaped; acorn ovoid, ½ in. long. W. China. Var. *rufescens*, Rehd. & Wilson (*Q. Ilex* var. *rufescens*, Franch.). Lvs. with yellowish gray, looser pubescence, older lvs. sometimes glabrous: scales of cup thicker, more villous. W. China.—*Q. arkaniana*, Sarg. Allied to *Q. marilandica*. Tree, to 70 ft.: lvs. broadly obovate, cuneate, at maturity glabrous beneath except tufts in the axils, 2–3½ in. long: cup shallow; nut broadly ovate, ½ in. long. Ark. S.T.S. 2:152.—*Q. austriaca sempervirens*, Hort.=*Q. Pseudoturineri*.—*Q. Boyntonii*, Beadle. Allied to *Q. stellata*. Shrub, 3–15 ft. lvs. obovate with 3–5 small obtuse lobes above the middle or nearly entire, 2–3½ in. long: cup turbinate. acorn about ½ in. long. Ala.—*Q. brevifolia*, Sarg.=*Q. cinerea*.—*Q. castaneaefolia*, C. A. Mey. Half-evergreen tree, to 70 ft.: lvs. oblong-lanceolate, serrate, tomentulose beneath, rarely almost glabrous, 4–6 in. long: cup with lanceolate recurved scales. W. Asia to N. Persia. G.W. 11, p. 199. Not or only half-hardy N.—*Q. Catesbaei*, Michx. Tree, to 60 ft.: lvs. similar to those of *Q. cuneata*, but rufous-tomentose when young, glabrous at length, except axillary tufts beneath, very short-petioled: cup turbinate with the scales extending above the rim and down the inner surface. N. C. to Fla. and La. S.S. 8:417.—*Q. Chapmani*, Sarg. (*Q. obtusiloba* var. *parvifolia*, Chappm.). Usually a shrub, rarely small tree; allied to *Q. stellata*: lvs. obovate-oblong and entire or slightly sinuately lobed toward the apex. S. C. to Fla. S.S. 8:370.—*Q. chinensis*, Abel. See *Q. sclerophylla*.—*Q. cinerea*, Michx. BLUE JACK. Small tree: allied to *Q. imbricaria*, but lvs. tomentulose beneath, smaller, elliptic to oblong-lanceolate, half-evergreen: cup saucer-shaped; acorn subglobose. N. C. to Fla. and Texas. S.S. 8:431.—*Q. cleistocarpa*, Seemen=*Pasania cleistocarpa*, Schottky (P. Wilsonii, Schottky, Wilsonii, Seemen). Evergreen tree, to 50 ft.: lvs. coriaceous, elliptic-oblong to oblong-lanceolate, acuminate, broadly cuneate at the base, lustrous above, covered beneath with a thin scaly grayish tomentum, becoming glabrescent, 2½–6 in. long: fr. in short dense spikes, subglobose, about ½ in. across, the cup nearly inclosing the acorn; scales adnate. Cent. and W. China.—*Q. coccifera*, Linn. Evergreen small tree or shrub: lvs. oval to oblong, spinose-dentate, almost glabrous, 1–2 in. long: cup with spreading or recurved rigid scales: maturation biennial. S. Eu. H.W. 2:25, p. 82.—*Q. cuspidata*, Thunb. See *Castanopsis* p. 2891.—*Q. densiflora*, Hook. & Arn. =*Pasania densiflora*.—*Q. Douglasii*, Hook. & Arn. Tree, to 60 ft., with dense, round-topped head: allied to *Q. Garryana*, but lvs. bluish green, less deeply lobed, often only sinuately dentate. Calif. S.S. 8:386.—*Q. dumosa*, Nutt. Evergreen rigid shrub to 8 ft. or

occasionally tree to 30 ft.: lvs. oblong to obovate, entire or sinuately toothed, pubescent, grayish green, ¾–2, rarely to 3 in. long: fr. usually solitary and sessile; acorn oval, ½–1½ in. long, embraced one-third to two-thirds by the cup. Very variable. Calif. S.S. 8:392.—*Q. Emoryi*, Torr. Evergreen tree, to 40 ft.: allied to *Q. chrysolepis*: lvs. usually cordate, oblong-lanceolate, spinose-toothed, soon almost glabrous, 1–2½ in. long: acorn oblong, ½–¾ in. high. Texas to Ariz. S.S. 8:397.—*Q. Engleriana*, Seemen (*Q. sutchuenensis*, Franch.). Evergreen tree, about 30 ft.: branchlets brown, soon glabrous: lvs. ovate-oblong, acuminate, rounded at the base, with few small spiny appressed teeth, sometimes entire, finally glabrous, 2½–5 in. long: fr. 1–3, short-stalked; acorn ovoid, scarcely ½ in.; cup with thin glabrescent brown scales, cup-shaped. Cent. China.—*Q. Esculua*, Linn. A S. European form of *Q. sessiliflora*, with the lvs. pubescent when young and deeply pinnatifid: synonym of *Q. sessiliflora* var. *aurea*, DC.—*Q. Fabri*, Hance. Tree, to 80 ft.: branchlets pubescent: lvs. short-stalked, obovate to oblong, obtusish, sinuately lobed with 6–10 pairs of short rounded rarely acutish lobes, grayish tomentulose and reticulate beneath, 3–6 in. long: fr. short-stalked; acorn oblong-cylindric, ½ in. long, cup glabrescent, brown. China.—*Q. Fargesii*, Franch.=*Q. oxyodon* var. *Fargesii*.—*Q. fruticosa*, Brot.=*Q. humilis*.—*Q. fulhamensis*, Hort. See *Q. Lucombeana*.—*Q. Gamberi*, Nutt. Small tree or shrub, very variable: allied to *Q. alba*: lvs. smaller, pale or yellowish green and usually finely pubescent below: fr. smaller, sessile. Colo. to Utah and Mex. S.S. 8:366, 367. Gt. 44, p. 7.—*Q. georgiana*, Curtis. Shrub, 6–8 ft., rarely small tree: allied to *Q. palustris*: lvs. smaller, less deeply lobed and lobes mostly entire. Ga. S.S. 8:425. Hardy.—*Q. Gilliana*, Rehd. & Wilson. Evergreen small tree, to 20 ft. or scrubby: lvs. subsessile, oval, rounded at the spiny-pointed apex, subcordate or rounded at the base, spinose-toothed, quite glabrous at maturity, 1–2 in. long: fr. sessile, ripening the first year; acorn ovoid, ½ in. long, inclosed nearly one-half by the hemispherical cup. W. China.—*Q. glabra*, Thunb.=*Pasania glabra*.—*Q. Graminifolia*, Linn.=*Q. Ilex*.—*Q. Haas*, Kotschy. Closely allied to *Q. pedunculata*: lvs. sparingly stellate-pubescent beneath, larger: fr. larger. E. Eu. W. Asia. Hardy.—*Q. Henryi*, Seemen=*Pasania Henryi*, Schottky. Evergreen tree, to 60 ft.: lvs. slender-petioled, oblong-lanceolate, acuminate, lustrous above, covered beneath with a thin scaly tomentum, finally glabrescent, 4–8 in. long: fr. in stout spikes 4–7 in. long; acorn depressed-globose, ½ in. across, embraced only at the base by the saucer-shaped cup. Cent. China.—*Q. heterophylla*, Michx. Supposed hybrid of *Q. Phellos* and *Q. velutina*: lvs. oblong, narrowed into the petiole, sinuately lobed or toothed or entire. S.S. 8:436.—*Q. humilis*, Walt.=*Q. cinerea*.—*Q. humilis*, Lam. Half-evergreen shrub, with oval, coarsely dentate lvs., grayish tomentose beneath: fr. almost sessile. Portugal. Sometimes *Q. prinoides* is sold under this name.—*Q. incana*, Roxb. Evergreen tree, to 60 ft.: allied to *Q. serrata*: lvs. oblong to ovate-lanceolate, acuminate, mucronate-serrate, with 14–20 pairs of veins, glossy above, whitish tomentose beneath, 3–6 in. long: fr. sessile; acorn about 1 in. long, at first almost inclosed by the campanulate, rather thin cup. Himalayas. Sometimes united with *Q. lanata*.—*Q. infectoria*, Oliver=*Q. lusitanica* var. *infectoria*.—*Q. insignis*, Mart. & Gal. the Mexican white oak, has been intro. recently by the U. S. Dept. Agric.: said to be best suited to a moist warm climate: a rapid-growing tree, erect, 75 ft., and making large branches 30–40 ft. from the ground: branchlets densely hairy: lvs. short-stalked, obovate-oblong, remotely serrate, hairy, on both sides, 5–9 in. long: fr. subsessile; cup ½ in. across, fulvous-pubescent.—*Q. inversa*, Lindl.=*Pasania thalassica*.—*Q. Koehnei*, Ambrozj (*Q. Pseudoturineri*, Veitch Cat., not Schneid.). Probably *Q. Ilex* × *Q. sessiliflora*. Lvs. oblong-ovate, cuneate, very obtuse at the apex, with few short lobes, glabrous; midrib yellow, changing to dull red in fall. Garden origin.—*Q. lanata*, Wall. Evergreen tree, to 80 ft.: allied to *Q. incana*: lvs. oblong-lanceolate, with 10–16 pairs of veins, remotely toothed, 4–8 in. long: fr. smaller, cup hemispherical. Himalayas.—*Q. lanuginosa*, Don=*Q. lanata*.—*Q. Ledna*, Nutt. Supposed hybrid of *Q. imbricaria* and *Q. velutina*: lvs. oblong or obovate-oblong, sinuately toothed or entire, rounded at the base. S.S. 8:434. Hardy.—*Q. Libani*, Oliver. Half-evergreen shrub or small tree: lvs. oblong-ovate, coarsely serrate, light green and at length almost glabrous beneath, 2–4 in. long: acorn almost wholly inclosed: scales little spreading. Asia Minor. R.H. 1872, p. 155; 1877, p. 173 (not p. 172, which is probably *Q. Agilops*). Gn. 1, p. 618.—*Q. Lucombeana*, Sweet (*Q. Cerris* var. *Lucombeana*, Loud. *Q. Cerris* var. *superbissima*, DC.). Supposed hybrid of *Q. Cerris* and *Q. Suber*. Half-evergreen tree to 70 ft., with broad, round head: lvs. oval-ovate, coarsely serrate, tomentose beneath, 2–3½ in. long: cup with subulate spreading scales. Probably of the same parentage as *Q. fulhamensis*, differing by symmetrical pyramidal habit and more corky bark. Gn. 27, pp. 476–8.—*Q. lusitanica*, Lam. Half-evergreen tree, sometimes shrub: lvs. oval to ovate-lanceolate, coarsely and deeply serrate, pubescent beneath, 1–2 in. long: cup with appressed scales, embracing one-half to one-third of the nut. S. Eu. Var. *infectoria*, DC., is more shrubby and has the lvs. less pubescent beneath.—*Q. macedonica*, DC. Evergreen tree or shrub: lvs. oval-oblong, serrate, light green and sparingly pubescent beneath, 1½–3 in. long: cup with the lower scales appressed, the middle ones spreading and the upper ones inverted, almost inclosing the nut. Macedonia, Albania.—*Q. macrocarpa*, Fisch. & Mey. Tree, to 50 ft.: allied to *Q. conferta*: lvs. larger and less deeply lobed, with 8–10 ovate lobes on each side, each lobe ½–1 in. long, sometimes with 1–3 teeth on its lower side, pale and densely soft-pubescent beneath, 4–7 in. long: fr. nearly sessile; acorn about 1 in. long, embraced nearly half by the cup covered with lanceolate pubescent scales. Caucasus to N. Persia. A handsome and hardy oak with large striking foliage.—*Q. macrolepis*, Kotschy. A variety of *Q. Agilops*, with larger, less deeply lobed lvs. and the scales of the cup large and strongly recurved. Crete.—*Q. Margaritella*, Ashe. Allied to *Q. stellata*. Shrub or small tree, to 30 ft.: lvs. obovate, with 3–5 rounded lobes, pale green or glau-

cous and pubescent on the veins beneath, $2\frac{1}{4}$ - $3\frac{1}{2}$ in. long: nut ovoid-oblong, $\frac{1}{2}$ in. long, one-half or less included in the cup. Va. to Fla. and Ala.—*Q. Mirbeckii*, Durand. Allied to *Q. lanuginosa*. Tree, to 100 ft.: branchlets glabrous or nearly so: lvs. ovate-oblong, with 9-12 short obtusish teeth on each side, pubescent beneath while young, 4-6 in. long: fr. 1-4 on a stalk $\frac{1}{2}$ -1 in. long. N. Afr. G.M. 56:139.—*Q. mongolica*, Hort., not Fisch.—*Q. lanuginosa*.—*Q. oblongifolia*, Torr. Evergreen small tree, to 30 ft., with spreading, often contorted branches: allied to *Q. undulata*. Lvs. ovate to obovate, entire or spiny-toothed, glabrous, bluish green, 1-3 in. long: cup embracing about one-third of the ovate nut. Ariz. to Mex. and W. Texas. S.S. 8:388. G.F. 1:140.—*Q. oxyodon*, Miq. Half-evergreen tree, about 30 ft.: lvs. oblong, acuminate, rounded or broadly cuneate at the base, serrate, veins prominent, close and numerous, glaucescent and silky beneath, $2\frac{1}{2}$ -7 in. long: fr. in short spikes; acorns ovoid, about $\frac{3}{4}$ in.; cup with concentric crenate rings, grayish tomentulose. Cent. China, Assam. Var. *Fargesii*, Rehd. & Wilson. Lvs. smaller: rings of cup entire.—*Q. phylliroides*, Gray. Evergreen tree or shrub, with broadly oval to oblong-oval lvs., crenately serrate, except at the base, glabrous, 1- $2\frac{1}{2}$ in. long: cup with appressed scales, small. Japan. S.I.F. 1:31.—*Q. ponicia*, Koch. Tree or shrub: lvs. oblong-oval, serrate, glabrous, glaucescent beneath, 4-6 in. long: cup with ovate-lanceolate scales, inclosing about one-half of the nut. Asia Minor. Gt. 40, p. 510. Hardy.—*Q. Pseudosieberi*, Santi. Evergreen or half-evergreen tree, allied to *Q. Suber*: bark less corky: lvs. more deeply serrate, thinner and less tomentose beneath: cup with recurved scales. Italy, N. Afr. H.W. 2, p. 82.—*Q. Pseudoturineri*, Schneid. (*Q. Aizoon*, Koehne, *Q. Turneri*, Hort., not Willd. *Q. austriaca sempervirens*, Hort.). Probably hybrid of *Q. Ilex* and *Q. pedunculata*. Half-evergreen: lvs. oblong-obovate, acute, cuneate, with about 5 pairs of ascending acutish lobes, somewhat pubescent beneath, midrib yellow, 2-4 in. long: fr. long-stalked. Garden origin.—*Q. Pseudoturineri*, Veitch Cat.—*Q. Koehnei*.—*Q. pumila*, Walt. *Q. Phellos* var. *pumila*, Michx. *Q. sericea*, Willd.). Half-evergreen spreading shrub, to 12 ft., similar to *Q. cinerea*: lvs. oblong to linear-oblong, entire or coarsely toothed, tomentulose beneath, glabrous at length: acorn subglobose, $\frac{1}{2}$ in. high; maturation annual. N. C. to Fla. S.S. 8:404.—*Q. Pigma*, Kotschy. Variety of *Q. Egilops*, with the lvs. less deeply and very irregularly lobed: cup embracing one-third of the acorn, with the lower scales loosely appressed, the upper ones recurved. Asia Minor.—*Q. reticulata*, Humb. & Bonpl. Half-evergreen tree, to 30 ft., or shrub: lvs. oval or obovate, spiny-dentate toward the apex, bluish green, tomentose and reticulate beneath, 1-5 in. long: fr. in slender stalked spikes; cup with appressed scales. Ariz. and New Mex. to Mex. S.S. 8:390.—*Q. rotunda*, Hort.—*Q. phylliroides*.—*Q. sclerophylla*, Hort., not Lindl. Sometimes *Q. Pseudoturineri* is cult. under this name. The true *Q. sclerophylla*, Lindl., belongs to Castanopsis, see *Q. sclerophylla*, below.—*Q. sericea*, Willd.—*Q. pumila*.—*Q. serrata*, Thunb. (*Q. acutissima*, Carruthers). Half-evergreen tree: lvs. obovate-oblong to oblong, acute, serrate, light green and glabrous below, 2-8 in. long: fr. sessile; cup with large, spreading and recurved scales, embracing two-thirds of the nut. Korea, Japan. S.I.F. 1:26.—*Q. Skinneri*, Benth. Tree, to 70 ft.: lvs. slender-stalked, ovate to ovate-lanceolate, sinuately serrate with bristly teeth, glabrous, 3-6 in. long: fr. sessile; acorn subglobose, large. S. Mex., Guatemala. G.C. 1841:116.—*Q. sutchuenensis*, Franch.—*Q. Engleriana*.—*Q. thalassica*, Hance—*Pasania thalassica*.—*Q. Turneri*, Willd. Half-evergreen tree: lvs. oval to elliptic-ovate, rounded at base, with 6-8 pairs of lobes, pubescent at least on the midrib beneath, midrib pale green. Origin unknown.—*Q. Turneri*, Hort.—*Q. Pseudoturineri*.—*Q. undulata*, Torr. Small tree or shrub: allied to *Q. Douglassii*; with smaller, less deeply lobed, bluish green lvs. pubescent below, nut smaller. Colo. to Ariz. and Texas. S.S. 8:385.—*Q. Ungerii*, Kotschy. Variety of *Q. Egilops*: lvs. smaller, lobed: cup with recurved scales, not much shorter than acorn. Asia Minor.—*Q. Veneris*, Kern. Tree: branchlets pubescent: lvs. subcoriaceous, broadly oblong, with 6-8 pairs of small acutish teeth, pubescent beneath or nearly glabrous, $1\frac{1}{2}$ -3 in. long: fr. nearly sessile; acorn embraced one-half by the hemispherical cup. Cyprus.—*Q. Wilsonii*, Seemen.—*Q. cleistocarpa*.—*Q. Wislizenii*, DC. Evergreen tree, to 80 ft.: allied to *Q. agrifolia*: lvs. ovate to oblong-lanceolate, sinuately dentate or entire, glabrous, yellowish green beneath, 1-5 in. long: acorn embraced about one-half by the cup. Colo. to Calif. and Texas. S.S. 8:406.

Note on Castanopsis. A recently concluded study of the Chinese oaks has enabled us to name these Chinese species of Castanopsis which had not yet been determined when the article on that genus was written, and has furthermore convinced us that several species usually referred to *Pasania* or *Quercus* must be included in Castanopsis.

The following species of Castanopsis are known to be in cult.: *C. ceratocantha*, Rehd. & Wilson. Tree, to 50 ft.: branchlets densely villous: lvs. oblong-lanceolate to ovate-lanceolate, acuminate, obscurely toothed above the middle or entire, brownish villous-tomentose beneath, 4-6 in. long: frs. in stout spikes to 8 in. long, $\frac{3}{4}$ -1 in. across, fulvous-tomentulose, with stout prickles $\frac{1}{4}$ - $\frac{1}{2}$ in. long and divided at the apex into several spreading spiny points; nuts 2-3, wholly inclosed. W. China.—*C. chrysophylla*, DC., see Vol. II, p. 682.—*C. cuspidata*, Schottky (*Quercus cuspidata*, Thunb. *Pasania cuspidata*, Oerst.). This species is already mentioned under *Pasania*, see p. 2479. The ovate pointed involucre is marked with 4 or 5 wavy concentric ridges of small tubercles and includes wholly the solitary nut. There are two varieties in cult.: var. *latifolia*, Rehd. & Wilson, with larger and broader lvs. to $4\frac{1}{2}$ in. long and to $2\frac{1}{2}$ in. broad; and var. *variegata*, Rehd. & Wilson, with small lvs. bordered by a broad, irregular, creamy white margin. G.C. II. 12:233.—*C. Fargesii*, Franch. Tree, to 100 ft.: branchlets glabrous: lvs. elliptic-oblong to lanceolate, acuminate, serrate above the middle, thinly and closely yellowish or grayish tomentulose

beneath, finally nearly glabrous, 2-5 in. long: frs. in stout spikes to 6 in. long, about $\frac{3}{4}$ in. across, with stout, often reflexed fascicled spines, about $\frac{1}{2}$ in. long; nut usually solitary, wholly inclosed. Cent. China.—*C. platycantha*, Rehd. & Wilson. Tree, to 80 ft.: branchlets glabrous: lvs. ovate-oblong to elliptic-oblong, acuminate, slightly toothed above the middle or entire, covered beneath, except the glabrous midrib, with a close fulvous tomentum, becoming paler the second year, $2\frac{1}{2}$ -5 in. long: spikes short, 3-6 fruited: frs. about 1 in. across, grayish tomentulose, densely covered with short and stout fascicled prickles; nuts wholly inclosed, 1-3. W. China.—*C. sclerophylla*, Schottky (*Q. sclerophylla*, Lindl. *Q. chinensis*, Abel). Tree, to 60 ft.: lvs. oval to oblong-ovate or oblong, acuminate, serrate above the middle, glabrous, glaucescent beneath, $2\frac{1}{2}$ -6 in. long: frs. in dense spikes with the peduncle to 4 in. long; involucre ovoid, with close concentric ridges of small tubercles, not wholly inclosing the solitary nut. E. and Cent. China.

ALFRED REHDER.

QUESNELIA (in honor of M. Quesnel, French Consul at Cayenne). *Bromeliaceae*. Caulescent or acaulescent herbs: lvs. spiny, in dense tufts: scape erect, nodding or pendulous; infl. spicate; bracts membranous or coriaceous, obtuse or acuminate, entire or serrate; fls. sessile, perfect; sepals usually free; petals free, convolute; stamens 6, equaling or a little shorter than the petals.—About a dozen species, natives of Guiana and Brazil.

arvensis, Mez (*Billbergia Quesneliana*, Brongn. *Q. cayennensis*, Baker). Lvs. up to $2\frac{1}{2}$ ft. long, $1\frac{1}{2}$ in. wide, armed with stout upturned spines: spike dense, up to 8 in. long, many-fld., the bracts rounded at apex, usually entire; fls. up to 2 in. long; sepals webby below; petals blue above; stamens much shorter than petals. E. Brazil. B.H. 1882:46 (as *Q. rufa*). F.S. 10:1028. Gt. 1875:834.

GEORGE V. NASH.

QUILLAJA (from *Quillai*, the Chilean name, which comes from *quilleau*, to wash: the bark of the tree contains saponin, an alkaline compound, which makes it useful as soap). *Rosaceae*. Glabrous evergreen trees, whose bark is sometimes saponaceous, occasionally grown in the greenhouse and hardy outdoors in the southern United States.

Leaves sparse, petioled, simple, thick-coriaceous, rather entire; stipules small, deciduous: peduncles axillary and terminal, 3-5-fld.: fls. polygamous-dioecious, rather large, tomentose, the lateral male, the central fertile; calyx leathery, persistent, lobes 5, broadly ovate, valvate; petals 5, small, sessile, spatulate; disk thick, fleshy, 5-lobed; stamens 10; carpels 5: follicles 5, oblong, obtuse, leathery, cohering at their base, many-seeded.—About 3 or 4 species, natives of S. Brazil, Chile, and Peru.

Saponaria, Molina. SOAP-BARK TREE. A large tree: lvs. $1\frac{1}{4}$ -2 in. long, ovate, shining, dentate, short-petioled: fls. white, about $\frac{3}{4}$ in. across, usually terminal, solitary, or in clusters of 3-5 on the same peduncle. Chile. B.M. 7568.—Cult. in S. Calif.

F. TRACY HUBBARD.†

QUINCE. The fruit and tree of one of the pome class, known as *Cydonia oblonga* (or sometimes as *Pyrus Cydonia*).

Few fruits play a more important part in ancient history than the quince, and yet there is hardly a fruit with equal or even poorer merit that in recent years has not received more attention. Scarcely a book is written on the quince and even practical mention of its merits, its culture, or its value is seldom made in the experiment station literature of America.

Perhaps this is due to the fact that the fruit can hardly be considered in the dessert class except when cooked; and yet it is said that in Persia and the near East it grows to such perfection that some varieties are esteemed when eaten raw.

The place of the quince in America seems to be a secondary one, to make marmalade, to preserve, to make jellies, and for flavoring purposes. The place of the tree among other fruits seems to be secondary also. It is seen most frequently in back yards and fence-corners and often in the lowest and dampest fruit land on the

farm. In a few cases, when its merits are recognized, it is given drier richer ground and cultivated with judicious care. Naturally, the quince is adapted to deep rich warm soils. The fertility of the soil should be strongly emphasized, as the root, instead of penetrating

3323. Flower of quince. It is borne on the wood of the season, not from an autumn fruit-bud. ($\times \frac{1}{2}$)

deeply, spreads out extensively and consequently is near the surface. It is slow-growing on any soil but responds very quickly to good fertility. On cold damp soils the fruit is inclined to be woody and it may possibly be for this reason that the quince is not more popular for preserving purposes. On the richer drier soils the quality is much improved. The idea is very prevalent that the tree is adapted to low ground. The lower grounds, generally speaking, are richer, but in this respect only may the trees be said to be adapted to it. Excessive moisture is harmful to the quince as to other fruits. Cultivation must be judicious. In many respects it should resemble that given the dwarf pear. The roots being near the surface, cultivation and especially plowing must be shallow. It is common practice to

3324. Quince, showing method of bearing at end of contemporaneous shoots.

ridge well up to the trees not only to protect the roots but to permit easy drainage; also the tree being very subject to fire blight, it does not permit of thorough cultivation with the consequent succulent wood-growth. Moderate cultivation in spring and early summer followed at once by a cover-crop or a good sod-mulch is considered good practice.

The quince tree is small, twisted and dwarf in its habit. It seldom reaches a height of more than 12 or 15 feet, although some grow higher. The larger number are much lower. Being dwarf in its habit, the quince tree can be planted as close as 13 to 15 feet in an orchard,

the latter distance being the more popular. Planted too close, it is forced upright, like other trees. The fruiting habit is distinct and peculiar, resembling no other orchard fruit, but is similar to the hickory and the walnut. The blossoms are produced on the current season's growth (Fig. 3323). A short growth starts from the terminal winter bud and on the end of this the flower and fruit are produced (Figs. 3324, 3325). There is no proper stem or peduncle to the fruit, but the quince sits close or sessile on a short leafy branch. The wood-growth is continued by an axillary bud of the previous season. This peculiar habit of growth gives the tree its crooked bunchy appearance. (Fig. 3326.)

Pruning should receive careful attention, otherwise the quince tree will soon become too thick and also more or less unshapely. When set in orchard, the young tree may be pruned to a short whip, as shown in Fig. 3327. The trunk is kept very short; some growers prefer to start the top as low as shown in Fig. 3328, but the former and probably still the prevailing practice is to grow a trunk like those seen in Fig. 3329. These longer trunks are convenient if one is to use the curculio catcher, as shown in Fig. 3330. The pruning consists in keeping the top open and well spread (Fig. 3328). To cause the top to spread and to keep it low and within bounds, more or less heading-in may be practised; but as the fruit-shoots spring from the ends of the branches, clipping-in of all the tree would remove practically all the fruit.

The questions of cultivation and fertilizers are largely inter-related. Thorough tillage makes available a large amount of plant-food, and consequently less fertilizer is necessary. However, too thorough cultivation and consequent succulent growth increases blight. The question of fertilizers comes down to one of producing moderate growth of a hardy resistant nature. This means that in cultivated orchards, heavy applications of nitrates or nitrogenous manures must be withheld. Phosphate and potash on the other hand can be

3325. The Orange or Apple quince. ($\times \frac{1}{4}$)

applied in quantity, especially on the lighter soils. The cover-crops will probably supply the necessary nitrogen. If growth is very slow, a light application of farmyard manure may be made. Lime and land-plaster can also be applied in quantity.

The fruit is sold in eleven-quart baskets, bushels, and barrels, and ranges from 75 cents to \$1.25 a bushel, depending on the market and the demand. In Ontario the demand is very limited and there are scarcely any orchards on a commercial basis. In the eastern states and especially New York State, there are some orchards of considerable size (Fig. 3329). The fruit, though apparently hard and long-keeping, is comparatively easily bruised or marked and must be handled with care.

The trees begin to bear a few fruits the second and third years after planting but can not generally be said to bear a profitable crop until ten to twelve years of age. The fruit is very subject to limb-rub and disease, and must be carefully grown to look well. The ordinary

practice is to spray the tree with dormant-strength lime-sulfur at the same time that the apples and peaches are sprayed and then again just after the fruit is nicely set with bordeaux mixture, to each forty gallons of which has been added three pounds of lead arsenate. Summer-strength lime-sulfur with the above amount of poison would give the same results for the summer spray. Judicious pruning also tends to thin the fruit and improve the quality.

Seedling stocks—Quince of Angers—are largely imported from Europe for

3326. Quince limb, showing branching and fruiting habit.

roots. These roots are used also for dwarfing the pear. The trees are grown much the same as other nursery trees. The seedlings are set in the nursery row in early spring and budded in August. By a year from the following spring, that is two years from the setting of the seedling, the trees are ready for the planter. The quince can also be propagated by cuttings, mound-layering and root-grafting, but the above-named method is the common one in practice.

Trees received from the nursery should be given the same care as other nursery trees. Heel them in carefully if the soil is not ready for planting. Plant about 2 inches deeper than the bud. Head at 15 to 20 inches. If budded trees are used and planted the proper depth, there is little or no danger from suckering.

The most damaging diseases are fire-blight, affecting the wood and especially the new growth; leaf-blight, affecting branches, fruit and foliage; and black-rot and bitter-rot, affecting the fruit. For the fire-blight, the worst disease, there is no direct remedy, but trees should not be allowed to over-grow, wild hawthorns and wild apples and pears near the plantation should be destroyed, and all affected parts should be removed promptly.

The most serious insect attacking the quince is the quince curculio (*Conotrachelus crataegi*). This may be controlled by spraying with six to eight pounds of lead arsenate to one hundred gallons of water, or in the place of

water bordeaux mixture at the proper season. This must be done when the beetles first make their appearance and again about ten days later. This insect is found on the quince in Ontario. The same insects as attack the apple generally attack the quince and the treatments are similar. Sometimes the jarring method

3328. a, The quince unpruned; b, same tree pruned.

is employed, as shown in Fig. 3330, as for the plum, the beetles being knocked off by hitting the tree with a padded mallet.

Orange (Fig. 3325) and Champion are the leading varieties of quince. The former is the variety most largely grown in Ontario and previous to 1870 was the only variety. It is large in size, skin golden yellow with greenish or russet color around stem. The flesh is tender and the flavor good. The season is late September and October. Its origin was southern Europe. The latter variety, of American origin, is large, pear-shaped and on the tree has a distinctly greenish yellow color. The tree is larger and taller-growing than Orange. The fruit is very late ripening. Other commonly grown varieties are Bentley, Fuller, Rea, Meech, and Van Deman.

F. M. CLEMENT.

QUISQUALIS (Latin, *who, what kind*). *Combretaceae*. Rambling subscandent large shrubs, including the rangoon creeper which is hardy in the extreme south

3329. New York quince plantation.

of the United States and is also sometimes grown in the greenhouse.

Leaves opposite, oblong or obovate, acuminate, entire; fls. in short spikes, axillary and terminal, white or red; calyx-tube prolonged, long and slender above the ovary, deciduous; petals 5; stamens 10, short; ovary 1-celled; fr. dry, coriaceous, 5-angled or 5-winged,

3327. a, An unpruned quince tree, one year old; b, the same pruned.

1-seeded.—About 4 species, chiefly Indian, 1 in Trop. and S. Afr. The name *quisqualis* means literally *who? what?* and is said to have been given by Rumphius in astonishment at the plant's behavior, for it is said to grow erect and shrub-like to a height of 3 ft., when it throws out from the base a new growth that climbs up the neighboring trees, after which the original shrub perishes. Many other interesting statements about this plant are made in B.M. 2033.

Quisqualis indica is cultivated in northern hothouses. For best results it should be planted in beds of soil composed of fibrous loam, peat, and sand. The flowers appear from June to September, and last well when cut. After flowering the plant should be cut back severely and water applied less frequently until the wood is

ripened. New growth starts the following spring. If the plant is kept in a very hot and humid atmosphere, it makes a rampant growth. It is remarkably free from insect pests and fungous diseases. Propagation is by softwood cuttings inserted in sand with bottom heat. (Emil Mische.)

indica, Linn. (*Celastrus nitans*, Hort. Reasoner, not Roxbg.). RANGOON CREEPER. Lvs. 4 in. long, nearly glabrous; calyx-tube extremely long (2-3 in.), slender, green; calyx-teeth triangular, acute, not acuminate; petals rose or scarlet; fr. with very sharp angles but hardly winged. Malaya. Widely cult. in tropics. B.M. 2033. B.R. 492. R.H. 1868:50 (as *Q. pubescens*).

F. TRACY HUBBARD.†

3330. Catching the curculio in a New York quince orchard.

R

RADERMÁCHIA (after J. C. M. Radermacher, 1757-83, a Dutch resident of Java, published a list of Javanese plants). Also spelled *Radermachera*. *Bignoniaceæ*. Ornamental trees.

Plants with large opposite, pinnate or bipinnate lvs. and large fls. in terminal panicles: calyx campanulate, truncate or dentate; corolla campanulate, with 4 or 5 included stamens: caps. linear, loculicidal; septum thick, spongy with the seeds in shallow impressions.—Only two species seem to be in cult.; they can be grown in subtropical regions only, and are prop. by seeds, also by air-layering and by cuttings.—Species 8, in S. E. Asia.

R. sinica seems to revel in the light sandy soil of the Florida gardens. Its abundant, large, fern-like, crimped bipinnate foliage and its luxuriant symmetrical growth combine to make it an object of great beauty. It grows to a height of 10 to 12 feet in one season, and if not cut down by a severe freeze it attains a height of 20 feet in two years, provided the soil is made rich by a good fertilizer. Planted out in a conservatory in the North it soon reaches stately dimensions. It is easily raised from cuttings placed in sand. (H. Nehrling.)

pentandra, Hemsl. (*Orbxylum flavum*, Rehd.). Evergreen tree, to 20 ft., glabrous: lvs. bipinnate, with the stout petiole 2-3 ft. long; lfts. oblong to oblong-lanceolate, entire, 3-7 in. long; panicle about 1 ft. long; calyx with 5 short teeth, splitting; corolla yellow; tube 2 in. long; limb spreading, about 3 in. across; stamens 5: caps. linear-cylindric, to 3 ft. long. Spring. S. W. China. H. I. 2728. S.T.S. 1:92.—Handsome tree with bold foliage and showy yellow fls. exhaling a heavy rather disagreeable odor; intro. by the Arnold Arboretum, and flowered in the greenhouse in 1903.

sinica, Hemsl. (*Stereospermum sinicum*, Hance). Evergreen tree: lvs. bipinnate; pinnæ 8, each with about 7 stalked, ovate-lanceolate entire lfts. obtusely acuminate, glabrous, about 2 in. long; panicle large, terminal; calyx campanulate, with 5 short triangular teeth; corolla pale sulfur-yellow, with funnel-form tube about 3 in. long and spreading roundish lobes about 1 in. long with crisped margin; caps. subterete, 16 in. long and ¾ in. thick. S. E. China.

ALFRED REHDER.

RADÍCULA (*little radish or root*). Syn., *Roripa*, *Nasturtium*. *Cruciferae*. Herbs, not cultivated except water-cress, horse-radish, and one or two others.

Plants mostly small, perennial, biennial, and annual, with small white or yellow fls. mostly in racemes: lvs. (or at least the lowermost) usually pinnate or pinnatifid, commonly glabrous: fr. a silicle or short silique, globular to cylindrical, with strongly convex nerveless valves; seeds usually many, small and marginless, in most species in a double row in each locule, the cotyledons accumbent.—Species more than 50, widely spread in eastern and western hemispheres, inhabiting low grounds, swamps, and pools or streams, mostly weedy in character. These plants formerly appeared under the name *Nasturtium*, which, however, dates only from 1812 whereas *Radicula* dates from 1756. These plants probably should bear the name *Roripa*, which see. The *nasturtiums* of gardens are very different plants, members of the genus *Tropaeolum*.

Armoracia, Robins. (*Cochlearia Armoracia*, Linn. *Nasturtium Armoracia*, Fries. *Roripa Armoracia*, Hitchc. *Armoracia rusticana*, Gaertn.). **HORSE-RADISH**. Stout perennial, 2-3 ft. high, from deep hard root: root-lvs. large and dock-like, oblong, crenate or sinuate or the lower early ones often deeply pinnatifid into narrow segms.; st-lvs. lanceolate or the uppermost linear, entire or toothed; fls. white and rather showy, numerous, the style short: pods seldom seen, globular, on ascending pedicels. Eu.; escaped in N. Amer. in moist places and along water-courses.—The long tough roots furnish the horse-radish of gardens. See *Horse-Radish*.

Nasturtium-aquaticum, Brit. & Rend. (*R. officinalis*, Groves. *Sisymbrium Nasturtium-aquaticum*, Linn. *Nasturtium officinale*, R. Br. *Roripa Nasturtium*, Rusby). **WATER-CRESS**. Spreading and rooting soft perennial: lvs. more or less irregularly pinnate, of 3-11 oblong or roundish nearly entire or somewhat angle-toothed segms. or lfts.: fls. white, in racemes that elongate in fr., the petals twice exceeding the calyx: pods cylindrical, an inch long more or less, on spreading pedicels, short-beaked. Eu., but widely naturalized in streams in N. Amer.—The herbage of this plant is

3331. Radish forms.—1, Triumph, very flat or oblate form; 2, Early Dark Red; 3, Early White Turnip radish; 4, Triumph, elongated form; 5, Triumph, typical form; 6, Early Dark Red, another form; 7, Gray Summer Oval; 8, Long Brightest Scarlet; 9, Wood Early Frame; 10, Early Deep Scarlet Olive.

much used for garnishing and for salads. See *Cress*. In the tropics *Nasturtium indicum*, DC. (see *Roripa*), is a desirable cress. This is an erect annual, with yellow fls. and deeply pinnatifid (rarely entire) radical lvs. It is said to have been cult. in Europe, but it is probably useless or at least unnecessary outside the tropics.

L. H. B.

RADISH (Latin, *radix*, a root). A name applied to certain forms or species of *Raphanus* (of the family Cruciferae), particularly to the kinds that produce thickened edible roots; these roots are eaten raw, except some persons cook the large summer and winter kinds. See *Raphanus*.

The radish is variable in size, shape, color, and consistency of root and in season of maturity. Varieties may be classified as spring, summer, and winter radishes; or as globular, half-long, and long radishes; or as red, white, gray, and black radishes. Figs. 3331-3333 show some of the forms.

The origin and nativity of the radish are questions of dispute. For geographical reasons, it is supposed that the radish is wild in temperate Asia, probably in the oriental part, although truly indigenous radishes are doubtfully known. Not infrequently the radish runs wild about gardens, and in that case the root soon deteriorates into a small slender woody and more or less fibrous member. It has been thought by some that the radish is only a modified form of the wild charlock, or *Raphanus Raphanistrum*. In fact, experiments were made on the charlock by Carrière, who was able in a few years to produce edible radishes from the wild plant (cf. *Cyclo. Amer. Hort.* IV:1487). While these investigations seem to be conclusive that the radish can be produced from the charlock, they nevertheless do not prove that such was the actual origin of the garden radish. DeCandolle, whilst accepting Carrière's experiments, was unable to understand how the radishes of India, China, and Japan could have originated from the charlock, since that plant is unknown in those countries and the radish has been grown there for centuries. It is possible that the radish was carried eastward from western Asia and Europe, but such has not been the general course of the migration of plants. It is possible that the radishes of the Orient are a different

The summer and winter radishes are not popular in this country unless among those of recent foreign origin. The winter radishes in particular are little grown. These are late-maturing kinds, requiring more of the season for growth, and of such large size and firm flesh that they keep well, as turnips are kept. The summer and winter radishes require no special treatment, except that plans must be made to allow them a longer period. In eastern Asia are singular kinds of radish that are little known here. In North America, the small spring radishes comprise practically the range of general cultivation.

The rat-tail radish, Fig. 3346, is grown for its much-developed soft pods, which may be used as are radishes and in the making of pickles. It is rarely grown in American gardens, although it is well worth raising as a curiosity. It is annual, and its cultivation presents no difficulties. There is also a fleshy podded radish of parts of India, with the edible pods short and soft.

The radish is one of the most popular of garden vegetables. It is of quick growth, and the product is secured at the time of the year when fresh vegetables are in demand. In order that radishes may be of the best quality, they should have made a rapid growth. The soil should be rich, light and loose,—one that drains readily and does not bake with heavy rains. Radishes fit for the table may be had in three to six weeks from the sowing, depending on the variety and the "quickness" of the soil. They are often grown as a catch-crop with other vegetables. They may be sown in the rows with early beets, peas or other crops, and they are usually mature enough for use before they seriously interfere with the main crop. Sometimes seeds of radishes are sown in the rows of slow-germinating plants, as carrots and parsnips, in order that the seedlings may mark the row and thereby facilitate tillage. Many of the radishes, in such cases, may be allowed to remain long enough to produce an edible tuber.

Aside from the root-maggot, the radish is relatively free from insects and diseases. When the root-maggot appears in any place, it is usually best to discontinue the growing of radishes in that area for two or three years, until the insects have been starved out. The maggots may be killed by an injection of bisulfide of carbon into the earth about the plants; but this is usually more expensive than the product is worth. Carbolic acid emulsion may also be used. Early radishes may be grown in hotbeds or cold-frames with the greatest ease, and in these places they are usually less subject to the attacks of the cabbage maggot, since the crop is matured in advance of the maggot season.

Radishes are readily forced in the winter months. It is necessary that the house be light. The soil should be a sandy loam, free from silt and clay. It is best to grow radishes in solid beds rather than on benches. They thrive best in a low temperature. The temperature during the day should not exceed 65° to 75° in the shade, and at night it may drop to 45° to 50°. If the temperature is too high, and particularly if the beds are given bottom heat, the plants tend to run to top rather than to root. The seed is usually sown in rows from 5 to 8 inches apart, and they are thinned in the row until they stand 2 or 3 inches apart. In order that the crop shall be uniform and mature simultaneously, it is advisable either to sift the seed or to transplant the young radishes. Galloway has found by experiment that radish seeds $\frac{3}{8}$ inch in diameter are too small to give a satisfactory and uniform crop. He therefore advises that seeds be run through sieves with a mesh of that diameter in order to separate the small specimens. In a certain experiment, he secured from two pounds of commercial seed nineteen and one-half ounces of large

3332. Half-Long Scarlet radish. ($\times \frac{1}{2}$)

species from those in Europe, although they are generally regarded as the same species. Recent experiments in France (Yvonne Trouard-Riolle, "Recherches morphologiques et biologiques sur les radis cultivés," Nancy, 1914) indicate that the cultivated radish has not been derived from *R. Raphanistrum* by cultivation, but that *R. sativus* is specifically distinct although little known as a wild plant. It is supposed that the Japanese radish is derived from one aboriginal form of *R. sativus* which is native of China and Japan, and that the European radishes have come from another aboriginal form.

seed, ten and two-third ounces small seed, the remainder being bits of gravel, sticks and other impurities. The chief value of this sorting lies in the greater uniformity of the crop. Almost every plant can then be relied upon to reach maturity. It is the practice in some houses to transplant the young radishes. The seed may be sown in flats or in beds at one end of the house, and when the radishes have made two or three leaves, they are transplanted into permanent quarters. In this operation, all the small and weak plants are discarded and the crop is therefore more uniform. It is supposed by some growers, also, that the breaking of the tap-root in the process of transplanting tends to make the tuber shorter and thicker and to induce an earlier maturity. By means of transplanting, the use of the house may be economized. Whilst one crop is growing, another may be started in a seed-bed or in flats. As soon as the first crop is removed, the ground may be thoroughly raked, fertilized, and the new plants put in. In some cases the new crop is transplanted between the rows of the old crop a few days before the latter is removed; but, unless the soil is rich and in good condition, it is better to wait until the crop is removed in order that the land may be thoroughly fitted for the new plants. Radishes are often forced in connection with lettuce, and they thrive well in the same temperature. The varieties most used for forcing, as also for the early spring crop in the garden, are the globular or half-long kinds. With these varieties, a depth of soil of 4 inches is sufficient for good results.

L. H. B.

Another view of the cultivation of the radish.

There are few garden roots in which fresh crispness is more essential to palatability than in the radish, or which can be more easily held in prime condition for so long after gathering, and usually one is able to secure roots of excellent quality from the market. On the other hand, an abundant family supply can be grown on a small area and the radishes can be quickly gathered and fitted for the table, so that every country garden or even town yard may be easily made to furnish a family supply. Radishes are cool-weather plants, and although when young or quickly grown they may be killed by severe or long-continued freezing, they will endure a moderate frost without injury; the plants do not thrive and the roots become tough and unpalatable if grown in a temperature above 60°. Radishes have been in cultivation since earliest historical times and there has been developed a wide range of varietal forms. In some varieties the plants develop very rapidly and are well suited for raising under glass or for growing in gardens in the spring and early summer, while other sorts are of slower growth and come to greatest perfection when planted so that they will escape the summer heat and develop during the cooler weather of autumn.

Forcing varieties.

A group of varieties of radishes has been developed in which the roots reach usable size very quickly,—in some stocks by the time the cotyledons are full sized and before more than three or four leaves have developed,—so that under favorable conditions a culture may be planted, grown to maturity, marketed and the beds made ready for a second planting within thirty or forty days. In this group the roots are in prime condition but a short time, quickly becoming pithy and unpalatable, particularly if subjected for even a few hours to temperatures above 60° F., and uniformity as to maturity is an important quality. Often in a lot of seed of uniform varietal character, the seed varies greatly in size of grains and it has been found that plants from the larger seed mature some days more quickly than those from the smaller grains, so that the sifting out and rejection of the smaller seed is often desirable.

There are a number of varietal forms suited for for-

cing, ranging in shape from those distinctly flat, through flattened, thickened or long turnip-shaped, and globular, to tankard or half-long, and in color from white through various shades of red and yellow to dark purple. In some varieties the color is of uniform shade over the whole root, in others more or less of the lower part is white, while in other strains the generally white surface is marked with dots and splashes of red. In the forcing of radishes, uniformity as to rapidity of maturing and in attractiveness of color are the most important qualities. The success of any culture is very dependent upon the varietal character of the seed used, and seedsmen are continually offering under new names stocks that are in reality but superior strains of the older varieties.

Spring radishes.

These are slower in coming into usable size than the forcing sorts, but the plants are larger, hardier both to cold and heat, and the roots are larger and continue in prime edible condition much longer. In garden cultures, the first sowing should be made as soon as the ground can be worked and ordinarily it will furnish usable roots in twenty-five to thirty days and remain in edible condition from five to twenty days. To secure a succession, two to five sowings should be made at intervals of ten to twenty days, but it is useless to attempt to grow radishes in the hot weather of midsummer, as they would not only make a poor growth but the roots would be tough, strong-flavored and unpalatable.

Radishes require for their best, or even for a good development, a rich friable soil which has been made so by heavy manuring and judicious culture in previous years rather than by recent working. The use of fresh stable-manure is very likely to result in ill-shaped coarse-grained strong-flavored roots, and the uniformity and symmetry of the root is very dependent upon the fertility and friability of the soil. The seed should lie some ten to twenty grains to the foot, in drills about 2 inches deep, and covered with about an inch of soil. It has been found advantageous, just before the starting plants begin to push through the soil, to cover the row with a liberal sprinkling of either tobacco dust, or of land plaster and kerosene, as a repellant to black beetle and other insects.

Seedsmen offer a wide range of varietal forms, ranging from the quick-maturing red or white Olive-Shaped, the Half-Long or the Long Scarlet, to the later-maturing longer-seasoned Chartier, or White Vienna, and the still larger later Strasburg or Stuttgart, which might be classed as summer varieties, although when planted so as to mature in the heat of midsummer they are likely to be strong-flavored and unpalatable.

Fall and winter radishes.

There are varieties which develop to usable size more slowly than the preceding and which remain crisp and tender much longer. They should not be planted until midsummer or later so that they may come to maturity in the cooler weather of autumn. These require more room for their best development than the spring varie-

3333. A dainty bunch of spring breakfast radishes. ($\times \frac{3}{4}$)

ties but are even more responsive to fertile well-prepared soil and frequent cultivation. They may be used as they reach desirable size and will stand considerable frost without injury, but should be pulled and stored much as one would carrots or parsnips so as to avoid severe freezing. The Long Black Spanish, the White Russian, the Chinese Scarlet Winter and Deep Scarlet Panier, the latter one of the most symmetrical and beautifully colored roots in cultivation, belong to this class which is well worthy of more general cultivation.

Chinese and Japanese radishes.

These are possibly the oldest of cultivated kinds. The large many-leaved plants are 2 feet or more across and form immense roots which not infrequently weigh forty to fifty pounds. The flesh is less agreeable in texture and flavor than that of the sorts more commonly grown, and though they have been loudly exploited by seedsmen, they have never come into very general cultivation in this country, except by the Chinese and Japanese who use them as a cooked vegetable more than as a salad.

Seed-growing.

There are few garden vegetables in which uniformity of varietal character is more important to satisfactory results than in the radish. This is particularly true of the quickly maturing forcing varieties, the seed of which is largely grown in Europe. As grown there, carefully bred stock-seed is sown thickly in narrow rows and when the most mature roots reach usable size, the crop is pulled, all immature or off-character roots are rejected, and those which are of satisfactory form, size, and color are promptly reset about 10 inches apart in rows about 3 feet apart and soon start into fresh growth and mature a crop of seed.

In this country, seed of both the forcing and larger-rooted sorts are commonly planted ten to twenty to the yard in drills, 3 feet apart, and when the plants are mature enough to indicate their varietal quality, the plantings are carefully gone over, the inferior and superfluous roots pulled and destroyed, and superior ones to furnish the desired quantity of stock-seed are pulled and set in a block by themselves, where there will be little danger of the flowers being fertilized by pollen from other plants.

The yield and quality of seed is very dependent upon uniformly favorable weather conditions inducing a quick, even growth, fertilization of the flowers by insects, and freedom from storms or exceptionally high temperatures. A hive or two of bees in the field will often materially increase the yield of seed. When the later and the most immature pods begin to ripen, the plants may be cut and laid in windrows or piles not over 3 to 4 feet deep on the threshing-floors and allowed to remain from ten to fifty days (depending upon weather conditions), until the stems are fully cured and dry. The seed may then be threshed out either with flails or machine and sacked, but must be watched, and if necessary, winnowed out, to prevent heating. In some localities it is a better practice, particularly with the later sorts, to leave the harvested plants under shelter until midwinter or early spring before threshing. Again, in case of some of the later harder-fleshed sorts, better yields are secured by not planting until autumn, and before severe weather, pulling, topping, and storing the small roots until spring, much as is done with seed-crops of beets or turnips.

W. W. TRACY.

RAFFIA is the Malagasy name of a palm which furnishes a staple article of commerce called raffia fiber. It is indigenous to Madagascar, where it grows without cultivation or attention of any kind. One palm leaf, or frond, produces eighty to one hundred long green

divisions 2 to 5 feet in length, like the leaves of the sugar-cane, but of a dark lustrous green color and thicker and stiffer. The under part of this green leaf is of a pale greenish yellow color, and from that side the inner skin is peeled off in the same manner as the skin on the outside of a pea pod, except that it peels off straight to the tip without breaking. It is then of the palest green, and after being dried in the sun assumes a light straw-color. This is the raffia fiber of commerce.

Raffia fiber is extensively used by the natives for making cloths called silk lambas and rebannas, which bring fancy prices in Europe and America, where it is used in the manufacture of various kinds of hats, and the like. A large trade is also had in raffia fiber in Europe for use in the manufacture of fancy baskets, but in America, while raffia fiber has been used to a limited extent in the manufacture of hats, its principal use is for tying vines, flowers, asparagus and celery bunches and for grafting. It is soft as silk and not affected by moisture or change in temperature so as to risk cutting or wounding the most delicate tissues, and it does not break or ravel when folded or knotted. These qualities bring it into general use in Europe, especially in the vineyards of France, where it is extensively used, and consequently maintains its price. It is virtually inexhaustible in Madagascar, the supply being limited only by the scarcity of labor. For export, the fiber is collected in large skeins, twisted or plaited, and then packed in compressed bales of about 100 kilograms (220 pounds) each. About 20,000 bales are exported annually.

CHAS. W. JACOB & ALLISON.

RAFFLÈSIA (named for Sir Thomas Stamford Raffles). *Rafflesiaceæ*. Fleshy parasites, with a solitary large sawfly fl. with a cadaverous odor rising from a superficial rhizome, leafless; fls. dicecious; perianth fleshy, the tube hemispherical at the base, solid in the male fls. and adnate to the ovary in the female fls., broad-campanulate above the ovary, limb 5-parted, the segms. imbricated in 1 row; ovary inferior, with numerous ovules. About 5 species, Malaya. *R. Arnoldii*, R. Br. Fls. flesh-colored, 3 ft. across, mottled with a thick fleshy rim or corona lining the upper part of the tube. In the male fls. there is a thick fleshy column within the corona and adherent to the perianth-tube and having at the top a wide flat plate, the overhanging margin of which is revolute and on which is placed a ring of sessile anthers. The female fls. are similar, but lack the anthers and possess an ovary adherent to the base of the perianth-tube and having a single cell. Sumatra. G. 7:547. J.H. III. 54:373.

RAILROAD-GARDENING. That phase or application of landscape gardening (or landscape architecture) which aims to improve the appearance of railway rights-of-way and station grounds; and, as an art of design, which lays out the approaches and makes the subdivisions of the grounds as best to serve convenience and beauty.

In this article, in a cyclopedia of horticulture, it is not intended to discuss the theory of design for railway properties, but rather to consider the plant-growing features; yet the layout must be taken into consideration. The subdivision of the property and the general theory of arrangement are necessarily controlled by the nature of the property itself, the extent of trackage, the need for passenger and freight access, the size of settlement to be served. Probably nowhere are the main elements more rigidly fixed by the necessities of the case, for the engineering requirements must be met; and yet there are large civic relations that should receive careful consideration.

In a small suburban railway station property, the planting feature may well be very prominent or even, to the general observer, dominant. Large trees are in place, and flanking lines of shrubbery and many good

XCV. Radish, in several varieties

garden features. In small cities, of say 10,000 inhabitants more or less, the station buildings become relatively more dominant and the planting falls into a subordinate place, and the gardening may take on the features of ornament; the approaches and the general layout begin to assume a civic character. In large cities, the architecture, arrangement, and formal approaches necessarily dominate, the plant materials are reduced to a very minor feature or disappear altogether, and the landscape architect approaches the work as a problem in city-planning and design. There remains the small country station in the farming country, which usually has been wholly neglected in respect to its landscape features and which has little expanse beyond the mere right-of-way; this is a problem quite by itself and which has not yet been studied to any

3334. A good rural station, with well-directed approaches, sward, trees, shrub-planting, and vines on the building.

extent. This application of the landscape art to real rural conditions will develop when the whole subject of country-planning begins to appeal to the public mind.

Historical sketch.

The railroad-gardening movement is best understood by a consideration of its historical development, and this is here attempted, although the treatment is not complete nor does it pretend to bring the subject down to date.

The movement in England.—Planting has been practised on the station grounds of some English railways for many years, but it is almost exclusively limited to purely ornamental gardening. The corporations do little beyond offering prizes to station-masters and their assistants. This system was put in operation about forty years ago on the Great Eastern, in about 1885 on the Midland, and at a more recent time on the Great Western Railway. The prizes range from 5s. to £5, and in 1900 aggregated £300 on the Midland Railway. The little planting that is done by the railway companies themselves is confined to a few trees of low growth near stations, to a background of shrubs for some of the so-called "platform gardens," and to sowing broom and gorse on certain slopes of the permanent way between stations. The "allotment gardens" that attract attention on English roads are small tracts near stations rented to employees of the roads, who use them as vegetable-, fruit-, and, to some extent, as flower-gardens. The Railway Banks Floral Association was an interesting factor in the improvement of English railway rights of way. Earl Grey was the originator of the novel and excellent scheme. The society was an organi-

zation for interesting owners of adjacent property, and for collecting money and materials for sowing and planting railway "banks" (downward slopes) and "cuttings" (upward slopes) of the permanent way, to the end of making them more attractive. The results have been eminently satisfactory.

Denmark.—In Denmark the railways belong almost without exception to the government, and improvements are begun when the roads are constructed. These consist of five classes of work: (1) planting of station grounds; (2) hedges as a substitute for fences; (3) snowshelters; (4) vegetation on embankments as a protection against erosion; (5) allotment gardens near block signal stations. Planting on station grounds is purely for esthetic purposes; the other features, while possessing some attractions, are maintained chiefly for their economic advantages. The materials for planting are obtained from nurseries ("planteskoler") owned by the roads and consist for the most part of shrubs, largely coniferous. These nurseries, as well as the entire planting, are under the supervision of a "plantoer," i. e., a chief botanical instructor. The allotment gardens, like their English namesakes, are tracts near the block signal stations where railway employees conduct vegetable- and fruit-gardens for their own use, and sometimes care for a few flowering plants.

Sweden.—Ornamental planting has been universal on government railways, as well as on most private railways in Sweden, since 1862. According to the Royal Administration of the Swedish State Railways, the following distinctions are made: (1) decorative and fire protective plantings on station grounds; (2) mixed plantings (decorative and economic) on "habitation grounds;" (3) plantings along the railway lines as hedges or for protection against snow. Station planting consists of trees selected to suit the climate of various parts of the country, of shrubs, and of perennials and annuals (flowering as well as bedding plants). At the largest stations (only about seventy-five) annuals are exclusively used for "modern or elegant combinations." The planting at habitation grounds consists of fruit-trees, small-fruits, a few ornamental shrubs, some flowering plants, and a small kitchen-garden. The state railways yearly plant out about 40,000 hard-wooded plants (trees and shrubs), and 400,000 soft-wooded plants (perennials and annuals), which are nearly all grown at five greenhouses, hotbeds, and nurseries situated in different parts of the country. On private railways the same plan is followed on a smaller scale.

In various other countries there are scattered examples of ornamental, economic, and protective planting on railways, including the cultivation of fruits along the rights of way of certain railways of Germany and of France.

The Canadian Pacific Railway Company has planted a considerable part of its right of way to tamarack and other suitable trees to supply the tie material of the future.

The director of the association called Het National Belang, at Utrecht, says that the association has contracts with the State Railway Company and the Holland Railway to plant the dykes of their roads. Different kinds of willows, low apple and pear trees (half-stam appel en peeren-bloemen) and wild prune trees are used, the fruit of the last being "used for jams."

The common quince is used to a limited extent in Uruguay for binding earth on embankments, and the paradise tree for shading station platforms. "The Ombu is the national tree of Uruguay,—useless as fuel or as timber, useless as food, but as welcome as Jonah's gourd at midday at certain seasons."

The Royal Railway Department of Siam reports through M. Kloke, acting Director General of Railways, that efforts have formerly been made to establish protective tamarind hedges along embankments in the Korat section, which were destroyed by cattle; Eucalyptus trees grown from seed received from Australia have developed quickly into "stately trees;" and good success has also resulted from the introduction of a tree from Manila which is said strongly to resemble the cherry tree, and is well suited for making "shady alleys;" and that India-rubber trees are used at smaller stations.

Remarkable work has been accomplished in Algiers. The director of the P. L. M. Railroad Company wrote some years ago that about 525,000 trees had been planted between 1869 and 1875, of which 495,000 were forest trees and 30,000 fruit-trees. The prevailing forest trees are eucalypts and locusts; others are mulberry, plane, pine, cypress, willow, poplar, oak, sycamore, and mimosa. About one-fifth of the forest trees were planted about stations and watch-towers for ornament, and the remaining four-fifths were used in protective plantings. The fruit-trees include mandarin, orange, lemon, medlars from Japan, pomegranate, apricot, and almond.

In Mexico some companies, notably the Mexican Central, maintain flower-gardens and parks at larger stations.

United States.—The first traceable indications of the movement in this country are about 1870. It was not until several years later that infrequent allusions to the work crept into print. From the year 1880, however, the movement gained in favor so rapidly that the late W. A. Stiles said of it in "Garden and Forest," March 13, 1889: "Railroad-gardening has come to be considered a necessary part of constructions and maintenance among prosperous and progressive companies seeking to develop local passenger business."

As nearly as can be determined with certainty, the first railroad-garden made in this country occupied the triangular plot of ground formed by the main line and the "Y" of the Baltimore & Ohio Railway, at Relay Station, where the through line from Washington joins the main line from Baltimore to the West. Frank Bramhall, of the passenger department of the Michigan Central Railroad, says of this plot: "I first saw it just before the Civil War." "Harper's Magazine" for April, 1857, gives a wood-cut of this station and its surroundings, but makes no mention of the planting.

The first example of gardening known to have been made by official order, as far as can be learned, was to be seen in 1869, on the line of the Central Railroad of New Jersey, on the stretch between Elizabeth and Bound Brook. The credit for this was directly due to the president of the railroad, J. T. Johnston. That gentleman was therefore one of the pioneers, if not actually the first American railway official to recognize the advantages, and to encourage the development of such improvement of station grounds.

Another early example, also on the Baltimore & Ohio road, is a little flower-garden which has been maintained at Buckhorn Point, on a narrow strip of ground between the tracks and the edge of a precipitous height overlooking the valley of the Cheat River.

In 1880, the Boston & Albany Company built a new station at Newtonville, Massachusetts, and a baggage-master (E. A. Richardson?) who took charge at that point in 1881 evinced an interest in the care of the grounds that attracted the favorable attention of the assistant engineer, who sent him men and material for grading

and sodding. This so encouraged the baggage-master that he solicited the townspeople for money to buy seeds and plants, and with such success that he maintained for three years a flower-garden that favorably impressed the higher officials of the road, and led to the establishment of similar gardens at other points, and eventually to the adoption of a system of planting which, under intelligent artistic supervision, has been radically changed in style till it now stands as the nearest approach to a comprehensive and consistent example of railroad-gardening. (Fig. 3334.) In 1882 and 1884 several new and exceptionally artistic stations had been built for the Boston & Albany Railway Company after designs by the late eminent architect, H. H. Richardson, and the latter date marks the adoption of a consistent scheme of permanent planting, aiming at nature-like effects instead of the purely ornamental, i. e., formal gardening, previously used. This happy result was due to the influence of Charles S. Sargent, of

3335. One method of treating a railway ground,—temporary formal ornament and no durable flank-planting.

the Arnold Arboretum, a director of the road, and to Wm. Bliss, its president. Designs for the improvement of the grounds around these stations were made by F. L. Olmsted, the veteran landscape architect, and since 1884 the development of these plans, as well as all of the horticultural interests of the road, have been in charge of a competent landscape gardener, E. A. Richardson, who says: "The plan followed is to conform the treatment and development of the station grounds to the adjacent ground: a natural style being followed amid natural surroundings, and a more cultivated style in highly cultivated regions; to utilize all natural advantages of ground surface, rocks, water, and native growths; to make large use of trees, shrubs, vines, and plants indigenous to the locality where improvements are being made; to supply beds for shrubs with from eighteen to twenty-four inches of good loam; and to plant so closely in the beginning that as the plants grow they can be thinned to supply other grounds as needed." It goes without saying that these methods are not only the most practical but that they insure the most artistic results.

Among the first railway companies to improve their station grounds by planting were the Central of New Jersey (1869), the Baltimore & Ohio (date uncertain), the Boston & Albany (1880), the New York Central & Hudson River (1880), the Erie (1881), the Southern Pacific (1885), the Pennsylvania (1886), and the Austin & Northwestern of Texas (1887). Other roads appreciate the value of the work and encourage it; and railroad-gardening has now become a recognized form of landscape improvement, although yet at its merest beginnings.

The methods.

In the public mind, railroad-gardening usually means the formal use of flower-beds about stations. Such work is ornamental gardening, not landscape gardening. Most of the so-called landscape gardening at railroad

stations is really merely decorative. Carpet-beds are relatively costly as compared with hardy shrubbery. They last but a few months and then leave bareness, while the best hardy trees and shrubs skilfully arranged are interesting all the year round. (Figs. 3335, 3336.) This making of nature-like pictures with relatively simple, inexpensive, and permanent materials is a much higher art than that involved in creating and maintaining flower-beds and a few summer-blooming plants. However, both have their places. Many a tired traveler is cheered by the bright colors of a neatly kept railroad station. Such displays are suitable at the stations if anywhere along the line. They are always preferable to dirt, ugliness, and a general air of indifference. But railroad-gardening never becomes worthy our best attention until it rises to the plane and importance of planning. (Fig. 3337.)

Some of the underlying considerations in the landscape improvement were stated in an editorial in

3336. A better method of treating the area.

"Garden and Forest," 1889, by the late W. A. Stiles, from which we quote: "Up to the present time, with few exceptions, railroad-gardening has failed to accomplish what the public has a right to expect of it from an artistic point of view. Instead of using their opportunities for increasing the taste and knowledge of the communities they serve, railroad managers have generally been satisfied to reproduce all that was glaringly bad in the prevailing horticultural fashion of the time. Perhaps this is inevitable, and it will continue so as long as they feel that they need not call for the advice of an expert of a higher class than the ordinary jobbing gardener. It is the old story—a man employs an architect to build his house, but thinks he needs no advice in laying out the park that surrounds it.

"The principles that underlie good railroad-gardening are simple. They relate,—so far as such gardening has been attempted,—to the immediate surroundings of country stations and to the shaping and turfing of the slopes rising and falling from the permanent way.

"The essential features are: convenient and abundant approaches, and some treatment of the ground not needed for approaches. This treatment should be at once economical and permanent, and of a character simple enough to be successfully maintained by the station-master and his assistants, under the inspection and with the occasional advice of a higher official charged with the management of the horticultural affairs of the corporation.

"The selection of a system of general treatment is the only difficult thing, and it is here that railroad managers have usually failed. Most railroad-gardens,—and this is as true of Europe as of America,—consist of a badly laid out and constructed approach, bordered with turf in which are cut as many large and often grotesquely shaped beds as can be crowded in and filled during four months of the year with the most showy and ill-assorted plants, and quite bare of all covering during the remaining eight months; of a few shrubs, mutilated almost past recognition by bad pruning, and by a clump of

pampas grass to complete the decoration; also often the name of the station in stones (mere 'toys'). As Bacon wrote three centuries ago, 'You may see as good sights many times in tarts.' Such grounds are not artistic, and are therefore bad from the point of view of the public. They are enormously expensive and difficult to maintain, therefore bad from the point of view of the railroad.

"If railroad-gardening is ever to become a potent and permanent means of public education, it must be organized upon a more economical basis, and with more regard to the laws of good taste and good business. This subject has already occupied the attention of a few thoughtful men, and we are confident that some progress has at last been made." Mr. Stiles commends the plans of the then new station grounds of the Boston & Albany Railway for "convenience, neatness, and simplicity. No beds, no brilliant flowers, no startling effects. They rely for attractiveness on convenient, well-kept roads, neat turf, a few good trees, and masses of well-selected and well-planted shrubs, among which herbaceous and bulbous plants are allowed to grow. The plan is simple, and when thoroughly carried out in the beginning it is easy to maintain."

On the treatment of the right-of-way between stations, Mr. Stiles says: "What is needed is a ground-covering that will be more permanent than turf and will not need its constant cutting and attention, and which can be secured without the enormous first expenditure for accurate grading and the deep soil that makes a grass slope presentable," and adds: "Such low plants as wild roses, dwarf willows and sumacs, sweet fern, bayberry, etc., when once established will prevent surface soil from washing, will not grow tall enough to interfere with operating the road, and if destroyed by fire would soon grow again from the root and re-cover the ground."

The proof of these deductions is seen yearly on many roads, where thousands of miles of railroad rights-of-way which, in the spring and early summer, are like ribbons of flowered brocade linking the towns together but later in the season become blackened wastes from accidental or intentional fires. Year by year this mournful program is repeated.

Railway officials offer no practical objections to the use of small trees and of shrubs between stations which apply when the work is done with discretion; viz., on the outer boundaries of rights of way that are 100 or more feet wide, on straight stretches, or on long tangents, and not on short curves or near grade crossings. The tracks should never be menaced by the danger of trees falling across them in wind-storms, nor should the telegraph wires and poles be interfered with, nor the view of the line obstructed. The danger to planting from fire can never be entirely eliminated until some non-spark-producing fuel is substituted for coal.

Planting for protection, as practised so far, includes: (1) covering banks with vegetation to prevent erosion, and (2) planting for protection from wind and snow, and from landslides. All this has been successfully done in various parts of the world. Snow-hedges are comparatively common at home and abroad. A notable example of confidence in the advantage of belts of trees for this purpose is seen in the groves planted some years ago by the Northern Pacific Railway Company. About 600,000 trees were set out in 1900, and the chief engineer of the road says: "This experiment has been undertaken to determine the possibility of substituting groves for snow-fences. It is necessary to protect all railway cuts in these prairie regions in some manner, as the strong winds across the treeless prairies cause the snow to drift badly. A strip 100 feet wide is cultivated to keep down weeds and overcome danger from fire, and through the middle of it runs a grove 60 feet wide, the inner edge being 125 feet from the center line and parallel with the tracks through cuts. The trees are

planted in parallel rows spaced 6 feet apart at right angles with and 3 feet apart parallel with the track. The two outer rows on each side are golden Russian and laurel-leaved willows; the third row from the outer margins, box-elder and ash; and the five central rows, cottonwood. This arrangement is expected to produce a dense grove, increasing in height from both sides to the center, which will furnish an effective windbreak." The feasibility of planting for protection against the encroachment of shifting sand on the seacoast, along rivers, and on so-called desert lands, has been demonstrated by the researches and experiments of the United States Department of Agriculture. The advantages of such plantings are sure to be eventually recognized and utilized by railway companies whose lines are exposed to this danger.

The disagreeable features and their suppression constitute an important phase of landscape improvement about railway properties. There are two important classes of disfigurement: defacement by signs, and defacement by abused and neglected grounds adjoining

probably be endured until mitigated by the efforts of municipal art and social-service leagues.

Protection of natural scenery is a prime consideration. Notwithstanding the prominence given in railway advertising to fine natural scenery, little credit seems due to railway companies in general for protecting such scenery. That they might wield a mighty influence for their own and the public good is proved by a few examples. It is learned that the unofficial work of representatives of the New York Central and the Michigan Central roads did much to create the public sentiment that led to the formation of government parks on each side of Niagara Falls, and that the same roads should be credited with comprehensive and extended efforts to secure legislation looking to the prevention of further defacement of the palisades of the Hudson. Many of the movements for protecting natural views and worthy objects have close relation with the improvement of railway properties.

3337. Plans of railroad-gardening.—On the left, Auburndale Station, Boston & Albany Railroad. The plan provides for a porte-cochère, driveways, steps to an overhead bridge and to an underground passage. On the right, Chestnut Hill Station, Massachusetts. Both reproduced from "Garden and Forest."

railway rights-of-way. The more noticeable of these is the display of hideous sign-boards that disfigure railway rights of way and, indeed, seem to have the right of way on highways of every description. These amount to a public nuisance that should be legally controlled, but as they are placed on adjacent land or buildings instead of on railway property, their direct suppression by railway officials is out of the question. These eyesores, however, furnish an added and cogent reason for massing plantations of small trees, shrubs, and vines at certain points along rights-of-way where the topography of adjacent land invites such disfigurement. These gaudy signs not only blot out or mar most fine landscape views (being adroitly placed to that direct end), but are allowed to distort otherwise unobjectionable farm buildings, while the approach to villages and towns is announced in screaming colors by the crowding together of these frightful adjuncts of civilization. While railway companies are not strictly responsible for these conditions, it is certain that they might sway public opinion and effect a much-needed reform by continuous, systematic work in the way of "planting out" the disfigurements, and by establishing attractive plantations wherever possible. This policy is likely to result in a reformation in the direction of the second source of unpleasant views from trains; viz., the unkempt, sordid, and often wretchedly squalid appearance of grounds adjoining rights-of-way through villages, towns, and small cities. If a park is maintained on the station grounds, nearby residents are likely to catch the good spirit and improve the looks of neighboring back yards. To this end, a rule against dumping on railway ground should be strictly enforced. The objectionable features that obtain in large cities must

Planting for economic purposes is among the possibilities along rights of way, for the purpose of producing timber for furnishing cross-ties, poles, and posts. It is asserted that, under competent supervision, this branch can be made not only to pay the entire expenses of the department but to become a source of revenue. This branch of the work appeals to practical railway men as perhaps no other phase can be expected to, and to what extent the fortunes of various groves of locust, catalpa, and tamarack influence the point of view of chief engineers it would be difficult to learn, but that numbers of them are turning otherwise unoccupied railways lands to this use is certain. In Indiana, for example, some railway companies have planted a part of their holdings with trees for the double purpose of growing timber for economic uses and to secure the resulting reduction in taxes, which is a feature of the state forestry law.

It is often asked whether the planting or horticultural department of a railroad can be made partly self-supporting. There seems little doubt that by one means or another this department might be made at least partly self-sustaining, but the consensus of opinion among railroad men is distinctly against the advisability of making it so, except indirectly. It is conceivable that railroad nurseries and greenhouses might supply planting stock to individuals to their advantage; and possibly railway rights-of-way aggregating immense areas might be planted to crops, perhaps to fruit-trees as is done to some extent in European countries (a project which has also been recently suggested for the roads of India), but the opinion is general that legitimate railroad business is limited to the transportation of people and of freight. Even if this is true, it is still certain that

the department may legitimately be made to yield substantial financial returns. This feature of the department work is as yet in a preliminary stage that makes definite conclusions as to the extent of its benefits impossible, but enough has already been accomplished to demonstrate the usefulness of a well-conceived and correctly developed policy of protective and economic planting.

The attainable ideals are many. Railway companies can do no more effective advertising than by demonstrating the possibilities of the country traversed for home-making. Instead of dreary wastes of dust and cinders, their way-station grounds should present refreshing scenes of shade and verdure. Their grounds should be treated according to the rules of landscape art that hold good in all planting. When adjacent land drops away, giving good vistas, these should be preserved; objectionable features should, as far as possible, be "planted out;" sky-lines should be varied, banks clothed, and variety and views supplied, particularly in flat and uninteresting regions. Railroad-gardens should be in the hands of those who will adorn instead of deface them; who will look to the formation of features that will take care of themselves after planting is established—features that require considerable expenditure, a good knowledge of trees and of shrubs, and a large amount of taste in the designer at the outset, but after being established, like the island gardens of Paris, "the hand of man might be withheld for half a century without their suffering in the least." This conception of railroad improvement is therefore much larger and more inclusive than the mere adornment of station grounds; eventually it will modify the development of the entire property over which passengers ride.

FRANCES COPLEY SEAVEY.

RAISIN: Grape, page 1386.

RAJÂNIA (named in honor of John Ray, 1628-1705). *Dioscoreaceæ*. Sts. from tubers, twining, and the habit of *Dioscorea*: lvs. alternate, undivided, hastate, cordate-oblong or linear: fls. dioecious, small, racemose, the male along the rachis often fasciated or in very short racemes, the female and sometimes both sexes simple and on short slender pedicels; perianth-segms. 6; stamens 6 in the male fls.; ovary ovoid or oblong; fr. reduced to one carpel through abortion, key-like, indehiscent.—About 10 species, W. Indies.

pleioneûra, Griseb. Fig. 3338. Tubers very irregular corks-combed: plant subshrubby, 5-6 ft. high: lvs. cordate-roundish or cordate-ovate, 2-5 in. diam., deltoid-pointed or cuspidate, 9-nerved; petiole about as long as or shorter than the lf., the aerial tubers produced at the base of the petiole: fls. dioecious, in racemes which are often fasciated, the male racemes compound, 3-8-fld., flexuose, the female simple: samara semi-obovate-oblong, bluntish, wing twice as long as the seed. Cuba and other islands of the W. Indies.

F. TRACY HUBBARD.

RAMIE: *Boehmeria nivea*, a fiber plant. See *Cyclopedia of American Agriculture*, Vol. II.

RAMÓNDA: *Ramondia*.

RAMÓNDA (named for L. F. E. von Ramond de Carbonnières, French botanist and traveler, 1753-1827). Usually spelled *Ramondia*, but first written *Ramonda*. *Gesneriææ*. Subcaulescent herbs with reddish lanate-villous hairs, suitable for rockwork.

Leaves basal, softly rugose: scapes leafless, 1- to few-fld.: fls. violet or pale purple; calyx free, 4-5 rarely 6-parted, the segms. ovate or oblong; corolla with scarcely any tube, rotate or broad-campanulate, 4-5 rarely 6-cleft, the lobes broad; perfect stamens as many as the corolla-lobes, affixed at the base of the

corolla; ovary superior, conical: caps. oblong, rather acute.—About 10 species, mountains of Eu.

Ramondia pyrenaica is one of the choicest and most interesting alpine plants. Few, if any, inhabitants of rock-gardens have been so often pictured. It is a small tufted, hardy perennial herb, like most alpine plants, and its scapes bear one or few flowers in spring. These are an inch or so across, and normally purple or violet, but there is a pure white variety which is in much favor. The ramondias vary in the number of their petals, or rather corolla-lobes. For example, *P. Nathaliae* often has four-lobed and five-lobed flowers on the same plant. The floral parts in the genus are in fours, fives, or sixes. These plants are rare and local in Europe and are interesting as being among the few alpine survivors of a family that is now essentially tropical. Although several ramondias are in the trade, only one is well known. This is *R. pyrenaica*, which is hardy in the eastern states. It is a beautiful dwarf alpine plant well adapted for the rock-garden. It is rather hard to establish but can be easily grown from seed. If seeds

3338. *Rajania pleioneura*, showing aerial tuber. ($\times \frac{1}{4}$)

are sown in the spring, and the small plants grown along in pots for the first summer and kept in a cool shady position, they will make neat little plants by the end of autumn. They should be kept in a coldframe for the winter. These one-year-old plants grown in pots are much easier to establish than younger plants. They may be planted in small pockets in the rockery in a slightly shaded and elevated position, and given good deep peaty soil. When the plants become established they will blossom freely, and if allowed to ripen their seed they will sow themselves freely amongst the rocks. Old plants can also be increased by division. They ought to be covered in winter with hay or dry leaves so that they will not be heaved out of the ground by the alternate thawing and freezing. The plants require perfect drainage.

A. Color of fls. purple or white.

B. Corolla 5-parted, rotate.

pyrenaica, Rich. Sometimes called **ROSETTE MULLEIN**. Fig. 3339. About 3 in. high: lvs. ovate, deeply toothed, hirsute with long rufous hairs: scapes many, several-fld., rarely 1-fld.; fls. purple; calyx and corolla 5-parted, the latter with subobovate lobes. May. Pyrenees. B.M. 236 (as *Verbascum Myconi*). G.C. III. 12: vii. Gn. 26, p. 129; 27, p. 197; 29, p. 343; 37: 30

and p. 31; 44, p. 555; 51, p. 205; 56, p. 228; 65, p. 113; 67, p. 71; 73, p. 374; 74, p. 327. G. 7:134; 33:139; 35:123. G.W. 1, pp. 16, 17; 15, p. 541. G.Z. 10:160. F.W. 1877:161. J.H. III. 34:187. R.H. 1866:330; 1906, p. 230; 1907, p. 447. Var. *alba*, Hort., is a white-fl. form. G. 23:485. Many inferior forms have been sent out under this name. *R. leucopétala*, Hort., *R. peregrina*, Hort., and *R. quercifolia*, Hort., are apparently only forms of *R. pyrenaica*. Well-grown specimens may have 6–12 scapes, each bearing 3–4 fls. $1\frac{1}{2}$ in. across.

BB. Corolla mostly 4-parted, more concave, short bell-shaped to funnelform.

Héldreichi, Janka (*Jancàa* or *Jankàa Héldreichi*, Boiss.). Lvs. ovate, entire, obtuse, silky white above,

3339. *Ramondia pyrenaica*. ($\times\frac{1}{2}$)

rusty-woolly below: scapes 1–2-fl. d.; fls. violet. According to Boissier it normally has a 5-parted calyx, 4-lobed corolla and 4 stamens. Thessaly. Gn. 55, p. 394. G. 35:197.

AA. Color of fls. yellow.

sérbica, Panc. This is said to be distinguished by its blue anthers; also the fls. are said to be normally 5-lobed. Servia. G.L. 24:146. Var. *Nathálie*, Hort. (*R. Nathálie*, Panc. & Petrov.), is more commonly 4-lobed than the type. Gn. 76, p. 203. G.W. 13, p. 553. S.H. 1:161.

F. TRACY HUBBARD.†

RAMPION (*Campanula Rapunculus*) is a vegetable sometimes cultivated for winter salads. The roots are chiefly used, generally in a raw state, but the leaves may also be used as a salad. The roots are white, a foot or so long, and spindle-shaped, like a long radish. They are ready for use in October or November and may be used all through the winter. According to Vilmorin's "Vegetable Garden," the seeds of rampion are the smallest of all kitchen-garden seeds, and their germinating power lasts five years. The seed may be sown in the open ground, either broadcast or in drills. The precautions usually taken with minute seeds must be observed. In order not to sow the seed too thickly, it is well to mix it with sand. The seed should not be covered, merely firmed into the soil. Frequent and careful waterings are necessary until the plants become established. Thinning is an important operation. Every plant allowed to remain should have at least 4 inches each way for development. The plants like a light rich soil, partial shade and water during the hot season. Although rampion is usually biennial, it sometimes runs to seed the first year, especially if the seed is sown early. It is, therefore, sometimes advisable to postpone seed-sowing until June. For botanical description, see *Campanula*.

RÁNDIA (named in honor of Isaac Rand). *Rubiaceae*. Trees or shrubs, erect or climbing, unarmed or spiny, grown in the warmhouse for their bloom or hardy outdoors in the extreme southern United States.

Leaves opposite, obovate-oblong or lanceolate, often leathery; stipules short: fls. small or large, solitary, corymbose or axillary, fascicled, rarely terminal, white, yellowish or rarely rose; calyx-tube ovoid, obovoid or turbinate, limb rarely dentate or lobed; corolla funnel-shaped or salver-shaped, tube short or elongated; limb 5-lobed (rarely more), short or elongated; stamens 5; ovary 2- very rarely 3–4-celled: berry globose or ovoid.—About 100 species in the tropical regions, especially in Asia and Afr. Closely allied to *Mitrostigma* and *Gardenia*.

A. Shrubs having spines.

dumetorum, Lam. (*R. floribunda*, DC.). A small tree or rigid shrub with stout straight often long spines: lvs. 1–2 in. long, short-petioled; fls. white or greenish yellow, fragrant, not large, solitary or rarely 2–3 on a peduncle; corolla $\frac{1}{2}$ – $\frac{3}{4}$ in. across: berry globose or ovoid, $\frac{3}{4}$ – $1\frac{1}{2}$ in. long, yellow. Trop. Asia.—Cult. in S. Fla.

Thúrberi, Wats. PAPACHI. An upright shrub, 6–8 ft. high, armed with slender spines, young branches canescent; lvs. obovate, attenuate to the short, winged petiole, obtuse or retuse: fr. globose or ellipsoidal, axillary, sessile or nearly so; seeds about 20, in black pulp. Lower Calif. and Sonora, Mex.—Intro. into Calif. The fr. is eaten by the Indians.

AA. Shrubs or trees without spines.

B. Corolla-tube $\frac{1}{2}$ in. long.

Fitzálanii, F. Muell. A glabrous tree: lvs. often over 6 in. long, shining, obovate-oblong or elliptical, obtuse; petiole rather long: fls. about 1 in. across, in loose, few-fl. cymes or the fertile fls. solitary: fr. globular, $1\frac{1}{2}$ in. thick or ovoid and longer, hard. Austral.—Cult. in Fla.

BB. Corolla-tube 4–10 in. long.

C. Lobes of corolla obtuse.

maculáta, DC. (*Gardènia Stanleyana*, Hook.). A much-branched shrub 10–15 ft. high: lvs. elliptical or obovate-oblong, $1\frac{1}{2}$ –5 in. long, $\frac{3}{8}$ – $2\frac{1}{2}$ in. wide, chartaceous, acuminate, narrowed at base; petiole usually with glands near its union with the midrib: fls. usually purple with white lobes, solitary, terminal or at ends of short lateral branches, sessile: fr. oval, oblong or globose, pointed, $1\frac{1}{4}$ –3 in. long. Trop. Afr. R.H. 1894: 60. B.R. 31:47. B.M. 4185. Gn. 38:322. G.C. III. 54:79. R.B. 30, p. 5.

macránta, DC. (*Gardènia macránta*, Roem. & Schult.). A climbing shrub, 9–30 ft. high: lvs. oval or obovate-oblong, opposite, cuspidate or caudate at the apex, narrowed at the base; stipules persistent, glumaceous: fls. solitary, fragrant, terminal, 6–10 in. long, whitish; calyx-lobes linear or linear-spatulate, spreading; corolla with a slender green or yellowish tube and oval obtuse lobes: fr. globose or somewhat pear-shaped. Trop. Afr. G.M. 51:221.

CC. Lobes of corolla acute.

Ruiziána, DC. A tender shrub with dark green lanceolate acute lvs., and white or pale yellow fls. terminal, solitary, sessile: corolla-tube somewhat hairy; lobes spreading: fr. cylindrical, yellow, 10-nerved. Brazil, Peru.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RANÈVEA (anagram of *Ravenea*). *Ravenea* of Bouché. *Palmaceae*. One species of palm perhaps allied to *Hyophorbe*, from which it differs, among other things, in its dwarfer habit, usually dioecious fls. and in the fls. being arranged alternately on the short branches of the spadix. The genus *Ranevea* seems, however, to be of uncertain relationship. Bouché's generic name *Ravenea* dates from 1878. It appears in Bentham & Hooker (3:883) as *Ravenia*. In spelling it is so similar to *Ravenia* of Vellozo, 1825, that the two cannot be distinguished by pronunciation, and there-

fore a new name was given. Cult. as in Hyophorbe. Prop. by seeds in stovehouse, under glass.

Hildebrandtii, Bailey (*Ravenea Hildebrandtii*, Bouché). Becoming 8–12 ft. high, but flowering under cult. when half that height, spineless, erect; lvs. elliptic-oblong or ovate-oblong in outline, long-stalked, pinnate, the pinnae 20 or more pairs and narrow-lanceolate-acute; spadix long-stalked, the staminate recurved and with short densely fld. spreading branches, the pistillate erect, with filiform strict branches thickened at the base; fls. pale straw-color, the calyx 3-lobed, the petals 3 and joined at the base, the stamens 6; fr. black. Comoro Isls. (east of Afr.). I.H. 27:403. B.M. 6776. G.F. 4:259.—An excellent dwarf palm, described by W. Watson to be “as elegant as *Geonoma gracilis* and as sturdy as a *Kentia*. It deserves to take a prominent place among garden palms, its small size, free habit, elegance, good constitution, being all in its favor, while in the freedom with which it flowers and produces seed we have an exceptional character among dwarf palms.” Perfect fls. are sometimes produced, although the plant is usually dioecious. Described as one of the most valuable recent palms. L. H. B.

RANÚNCULUS (Latin name for a little frog; applied to the genus by Pliny in allusion to the wet places in which many of the species grow). Including *Batrachium* and *Ficaria*. *Ranunculaceæ*. BUTTERCUP. CROWFOOT. Annual and perennial herbs, a number of which are grown in the garden and sometimes in the greenhouse for their showy flowers. Most of the species are hardy perennials, some of them aquatic.

Leaves entire or dissected; cauline lvs. alternate, often few; fls. white, yellow or red, terminal, solitary or panicled, rarely sessile at the branch axils; sepals 3–5, caducous; petals all or most (up to 15) provided with a honey-bearing pit or an enlarged conspicuous or rarely minute scale; stamens shorter than the sepals and petals, frequently numerous, sometimes only few in small-fld. species; carpels numerous, 1-ovuled; achenes compressed or subglobose, smooth or variously striate, costate, rugose, or spiny.—About 300 species dispersed all over the world, mostly in the temperate and colder regions, few in the tropics. The structure and arrangement of the achenes is well shown in Fig. 3340.

Culture of the ranunculuses. (E. J. Canning.)

The culture of ranunculuses in gardens and by florists has been confined chiefly to the Persian and Turban ranunculus, *R. asiaticus*, since the Asiatic species is far more attractive than the European. In England and in other European gardens, *R. asiaticus* has been in cultivation a very long time. Parkinson mentions it in his *Paradisus*, published in 1629. He termed it “the double-red crowfoot of Asia.” Since his time *R. asiaticus* and its varieties have been greatly improved, both in size of flowers and variety of colors. The flowers are very double, almost globular in outline, and often exceed 2 inches in diameter, while the colors now embrace almost every shade except blue, and some are striped and variegated. A well-grown mass of these charming flowers when in full blossom is a sight not soon forgotten. They are not so well known in American gardens as in those of England or at least not in the eastern states, since the writer has rarely met with them or seldom seen any reference to them in the horticultural periodicals. They are not adapted to either spring or summer bedding. Their season of blossoming in this country is about the last week in May and the first week in June, which is too late for spring bedding, while the season of blossoming is too short for summer bedding. Therefore a position should be given them in

the herbaceous border where they will receive some shade during the warmer parts of the day, or a level place in a rock-garden with a northern aspect. The roots are tuberous, being like miniature dahlia roots. They are not hardy, at least not in any of the northern states. The tubers should be carefully lifted after the foliage has all “ripened off” (which occurs usually toward the end of August), and stored until the following spring in some cool shed where they will not freeze. They should be planted as soon as the frost is well out of the ground in spring, about 2 inches in depth and about 6 inches apart, making the soil very sandy on top so that the leaves will push through readily without heaving the soil. Like their congeners the European ranunculi, they like plenty of moisture at the roots during the growing season, and if they can be shaded from the sun when in flower their blossoming period will be materially lengthened. They may also be grown for flowering in the greenhouse. The gardener may well have a few pans each year, planting the roots in pans of light soil toward the end of January and placing them in the coolest greenhouse, where they will blossom toward the middle of April. He will probably prefer the Turban varieties, since they are stronger-growing and rather larger than the Persian. The species may be propagated by seeds, but this process is not worth while because the bulbs may be procured so cheaply.—Of the native and European species of ranunculus, those of the *Batrachium* section, such as *R. aquatilis* and its varieties, are interesting aquatic plants, while *R. repens* var. *flore-pleno*, and *R. amplexicaulis* are useful as subjects for the bog-garden.—For herbaceous borders or moist corners in the rock-garden *R. aconitifolius* var. *flore-pleno*, *R. cortusæfolius*, *R. anemonoides*, *R. parnasifolius*, and *R. Ficaria* are the only species worth growing. These are readily propagated from seeds or by division of the plants in spring. See the supplementary list, p. 2909, for some of these.

KEY TO THE SPECIES.

- A. *Sepals* 3. 1. *Ficaria*
- AA. *Sepals* 5.
 - B. *Achenes* transversely wrinkled, emarginate: petals with a nectar-bearing pit at base.
 - C. *Lvs.* setaceous-multifid: sts. submerged. 2. *fluitans*
 - CC. *Lvs.* subreniform or rounded-cordate: sts. creeping in the mud. 3. *hederaceus*
- BB. *Achenes* smooth or nearly so: petals usually with a nectar-bearing pit and scale, the latter sometimes imperfect or very minute in c.
 - C. *Roots* fascicled, more or less tuberous-thickened.
 - D. *Sepals* reflexed.
 - E. *Head* of achenes cylindrical-spicate; achenes slightly verrucose; beak straight: fls. numerous. 4. *psilostachys*
 - EE. *Head* of achenes ovoid; achenes pubescent; beak recurved: fls. few.

3340.
Head of
buttercup
achenes.

- F. *Lf.-blades 3-lobed or 3-parted:*
beak of achene recurved..... 5. *monspeliacus*
- FF. *Lf.-blade pinnately compound,*
lfts. or segms. 5-7: beak of
achene straight..... 6. *orthorhynchus* [chus]
- DD. *Sepals spreading.*
- E. *Lvs. ternately or biternately cut:*
head of achenes cylindrical;
achenes glabrous..... 7. *asiaticus*
- EE. *Lvs. subcordately reniform,*
incised, lobes cut and dentate:
head of achenes short-ovoid;
achenes hairy on the sides.... 8. *cortusæfolius*
- CC. *Roots fibrous, not fascicled or tuber-*
ous thickened (bulbous in No. 11.)
- D. *Fls. white, rose or rarely purple*
(yellow in a double-fl. variety of
No. 11).
- E. *The lvs. dissected.*
- F. *Sepals pubescent.*
- G. *Petals 5*..... 9. *glacialis*
- GG. *Petals 12-20*..... 10. *Matthewsii*
- FF. *Sepals glabrous.*
- G. *Sts. several-fl.*..... 11. *aconitifolius*
- GG. *Sts. 1-3-fl.*
- H. *Blades palmately 3-lobed:*
petals 5..... 12. *alpestris*
- HH. *Blades pinnately cut, lobes*
3-lobed: petals 8-10..... 13. *rutæfolius*
- EE. *The lvs. not dissected.*
- F. *Blades sessile and amplexicaul.* 14. *amplexicaulis*
- FF. *Blades petioled.*
- G. *Sepals glabrous: lvs. linear or*
lanceolate..... 15. *pyrenæus*
- GG. *Sepals pubescent: lvs. rather*
cordate or ovate-rounded.... 16. *parnassifolius*
- DD. *Fls. yellow (see also a double va-*
riety of No. 11; fls. scarlet in a
form of No. 28).
- E. *Lvs. not divided (although some-*
times lobed).
- F. *Lf.-blades rounded-cordate or*
reniform..... 17. *insignis*
- FF. *Lf.-blades linear or lanceolate.*
- G. *Plants alpine, 6-12 in. high:*
lvs. linear or narrow-lanceo-
late: sepals glabrous..... 18. *gramineus*
- GG. *Plants aquatic, 2-3 ft. high:*
lvs. lanceolate, sessile and
somewhat clasping: sepals
villous..... 19. *lingua*
- EE. *Lvs. divided.*
- F. *Stolons present*..... 20. *repens*
- FF. *Stolons lacking.*
- G. *Base of st. bulbous*..... 21. *bulbosus*
- GG. *Base of st. not bulbous.*
- H. *Rootstocks present.*
- I. *Sts. glabrous: lvs. all radi-*
cal..... 22. *Enysii*
- II. *Sts. pubescent: lvs. both*
radical and cauline.... 23. *montanus*
- HH. *Rootstocks absent (though a*
short, erect, thickened cau-
dex is often present).
- I. *Azis of infl. hirsute*.... 24. *polyanthemos*
- II. *Azis of infl. glabrous.*
- J. *Sepals spreading.*
- K. *Sts. lax or weak:*
petals 6-15: upper
cauline lvs. wanting.... 25. *californicus*
- KK. *Sts. strictly erect:*
petals usually 5:
upper cauline lvs.
present.
- L. *Peduncles terete,*
not striate..... 26. *acris*
- LL. *Peduncles striate*... 27. *lanuginosus*
- JJ. *Sepals reflexed.*
- K. *Fls. many on a st.*... 28. *constantino-*
politanus
- KK. *Fls. 1 or 2 on a st.*... 29. *anemone-*
folius

1. *Ficària*, Linn. (*Ficària Ficària*, Karst.). Perennial: roots fleshy, thickened: sts. short, decumbent, branched at base, often with bulblets in the lf.-

axils: lvs. 1-2 in. long, ovate, cordate, crenate (sometimes entire), somewhat fleshy; petioles long, broad: fls. solitary, golden yellow, about 1 in. across; sepals 3, spreading, oval, concave; petals 8-9, scale at base of petal emarginate: achenes 15-20, in a globose head, very convex, truncate, short-puberulent; receptacle glabrous. April, May. Eu., adventive in N. Amer., Mass. to D.C. B.B. (ed. 2), 2:117. Var. *flòre-plèno*, Hort., is a double-fl. form. Var. *grandiflorus*, Hort., is merely a large-fl. form. J.H. III. 53:371. Var. *ochroleucus*, Hort., is a form with whitish yellow fls., offered in the trade.

2. *fihtans*, Lam. Perennial, aquatic: sts. submersed, usually very long: lvs. submersed, petioled, the lower lvs. often long-petioled, about twice 3-parted, divisions very long-linear, 2-3-cleft, segms. nearly parallel: peduncle tapering, bearing a spreading raceme: fls. large, white; petals often more than 5, broadly obovate, many-veined, contiguous, persistent: achenes obovate, inflated, much rounded at the end laterally, apiculate; receptacle conical, naked. June. Rivers, Eu.

3. *hederaceus*, Linn. (*Batrachium hederaceum*, S. F. Gray). Perennial, semi-aquatic: sts. creeping, rooting at the nodes: lvs. subreniform or rounded-cordate, 3-5 shallow rounded lobes widening to their base and usually entire or notched at the apex, usually opposite and with a black half-moon; stipules various: peduncles usually shorter than the lvs.: fls. $\frac{1}{6}$ - $\frac{1}{4}$ in. across, white; petals very narrow, 3-nerved, distant, sometimes hardly exceeding the calyx; stamens 5-12; style prolonging the nearly straight inner edge of the ovary: achenes few, glabrous, obovate, laterally compressed at the base, inflated or rounded at the top, mucous; receptacle globose, naked. June. Shallow ponds or mud. W. Eu. and naturalized in N. Amer., Newfoundland to S. Va. B.B. (ed. 2) 2:116.

4. *psilostachys*, Griseb. (*R. nyssanus*, Petrov.). Perennial, about 18 in. high, appressed silky pubescent: sts. branched: radical lvs. broadly orbicular, subcordate, deeply 3-parted, divisions cuneate, incise-lobed: fls. numerous, large, shining citron-yellow, 2 in. across; sepals reflexed: achenes in a cylindrical spike, ovate, slightly verrucose, beak straight, as long as the body. Serbia, Macedonia, and Greece. G.C. III. 46:163.

5. *monspeliacus*, Linn. Perennial, $1\frac{1}{2}$ ft. high, white-woolly or sericeous: sts. erect, few-fl.: lvs. woolly, ovate-rotund, cordate, the radical 3-lobed, lobes cuneate, trifid or 3-toothed; the upper 3-parted, lobes entire, linear: fls. yellow; sepals hirsute, reflexed; petals obovate: achenes numerous, pubescent, compressed, beak recurved and equaling the carpel; receptacle glabrous; head of achenes ovate. April, May. Medit. region.

6. *orthorhynchus*, Hook. Perennial, 10-18 in. high, hirsute to nearly glabrous: sts. erect from a fascicled root of thick fibers: lvs. mostly oblong, pinnately compound; lfts. or segms. 5-7, lower commonly short-petioluled, usually cleft or incised: fls. yellow, sometimes purple outside; sepals reflexed, soon deciduous; petals 7-16, $\frac{1}{3}$ - $\frac{1}{2}$ in. long, obovate, much surpassing the sepals: achenes in an ovoid head, not numerous, ovate, nearly 2 lines long, strongly margined, beak slender, subulate, rigid, straight, nearly as long as the body. May-July. Wet places, Brit. Col. to Ore. and Mont. Var. *platyphyllus*, Gray (*R. maximus*, Greene), is more robust, growing 1-5 ft. high, the lfts. often 3 in. long, laciniately cleft and incised and the petals often larger than the type. N. Utah, Idaho, Wash. to Calif. and reported from Brit. Col.

7. *asiaticus*, Linn. (*R. orientalis*, Hort., not Linn.). Fig. 3341. Perennial, 6-12 in. high: sts. erect, simple or branched, somewhat appressed hirsute: lowest radical lvs. cuneate-ovate, dentate at the obtuse

apex; the others ternately or biternately cut, segms. ovate or oblong, toothed or deeply trifid, sometimes many-fid: fls. 1-4 to a st., of many various colors; sepals spreading; petals large, obovate, very obtuse, much exceeding the calyx: achenes papery-compressed, oblong, glabrous, attenuate to a much shorter beak which is hooked and black at the tip; head of achenes cylindrical. May, June. S. E. Eu., Asia Minor, Syria and Persia. F.S. 16:1679 (fl.-pl.). G.M. 49:13.—Very variable; the common garden ranunculus of which there are several highly developed strains, many of which are very double. The fleshy roots are sold as

3341. Persian ranunculus.—*R. asiaticus*. (×½)

bulbs. The cult. forms of *R. asiaticus* are constantly increasing in number. They are of two main types: (1) The florists' section, called PERSIAN RANUNCULI, or true *R. asiaticus*. These require more care than the others. They are very variable in form and color, and are the most highly cult. members of the genus. (2) The gardeners' section, called TURBAN RANUNCULI, or var. *africanus*, Hort. (*R. africanus*, Hort.). Compared with the first section, these have larger, broader, 3-parted lvs., not so much cut: fls. larger and broader, with many crisp petals, not flat and spreading but erect and curved inward, forming a spherical fl., as in the double peonies. Var. *superbissimus*, Hort., is a taller-growing very large semi-double-fl. form. July-Sept. R.B. 16:133.

8. *cortusæfolius*, Willd. Perennial, 1-3 ft. high, velvety hairy: roots thick, fleshy, fascicled: sts. branched, corymbose above: lower lvs. long-petioled, subcordately reniform, incised lobes cut and dentate; cauline lvs. nearly sessile, 3-5-lobed, lobes narrow; floral lvs. sessile, lanceolate: fls. several to many in a terminal and axillary rather paniculate infl., yellow; sepals 5, ovate to lanceolate, spreading, green with pale margins; petals 5, large, broadly obovate, glossy: achenes compressed, hairy on sides, tapering into recurved beaks, nearly their own length; head of achenes short-ovoid. May. Isl. of Teneriffe, Canary Isls. B.M. 4625. Gn. 45:28. Gn.W. 8:517. J.F. 3:239.—Not very hardy and needs protection in winter and early spring. It is well suited for pot culture. It is increased by division of the roots in autumn.

9. *glaciælis*, Linn. Perennial, 3-6 in. high: sts. reddish brown, 1-3-fl.: lower lvs. petioled, rather fleshy, palmately 3-parted or 3-cleft, lobes trifid, or again lobed, the lobules rather obtuse; the other lvs. similar but sessile and involucrate: sepals very hirsute; petals obovate to cuneate, obtuse, white or reddish: achenes very numerous, obliquely obovate, slightly compressed, smooth, glabrous, margin above membranaceous-winged; beak straight; receptacle glabrous. May-Aug. Alpine Eu., Arctic regions, Greenland. Gn. 45, p. 28; 48, p. 501. G.C. III. 53:117.—With age the fls. become coppery red.

10. *Mátthewsii*, Cheesm. Perennial, 15-20 in. high, glabrous or a few weak hairs on the petioles and peduncles: radical lvs. reniform or orbicular ternate-cut, the main divisions petioluled, coarsely toothed or lobed; petioles stout, 3-9 in. long; cauline lvs. sessile, deeply toothed or lobed: fls. 1-4, large, pure white, sweet-scented, 2½-3 in. across; sepals 5, slightly villous, reflexed; petals numerous, 12-20, oblong-cuneate, rounded at apex; gland solitary, large and basilar: achenes forming an oblong-globose head ½ in. or more diam., turgid, pilose, beak long, subulate. New Zealand. Gn. 78, p. 2.

11. *aconitifolius*, Linn. Perennial, 6 in. to 3 ft. high, pubescent: sts. branched: lvs. palmately 3-5-parted; segms. incise-dentate; upper lvs. sessile with linear-lanceolate lobes: fls. white, several to a st.; sepals flat, glabrous; petals oblong, cuneate or orbicular: achenes 6-15, obovate, laterally subcompressed, nerved, glabrous, beak straight, recurved at the top; receptacle villous. May, June. Mountains of Cent. Eu. Gn. 70, p. 135. G.M. 45:196. Var. *fiore-plèno*, Hort. (*R. aconitifolius* var. *plenus*, Hort.), called WHITE BACHELOR'S BUTTON and FAIR MAIDS OF FRANCE, has large double white fls. Gn. 45, p. 29; 48, p. 506; 65, p. 24. G. 4:415; 10:411; 36:226. Var. *luteo-plèno*, Hort., has double golden yellow fls.—This species and its varieties are well adapted for border planting.

12. *alpéstris*, Linn. Perennial, 3-6 in. high: st. usually 1-fl.: lvs. petioled, orbicular-cordate, 3-lobed, lobes rather obtuse, lobate-crenate at the top, sometimes the lvs. are trifid or hardly so; this is true of the sessile cauline ones: sepals glabrous, spreading; petals 5, white, rounded-obcordate, emarginate: achenes obovate-globose, glossy, glabrous; beak straight, hooked at the summit. Mountains of Eu.

13. *rutæfolius*, Linn. Perennial, 3-6 in. high: st. usually 1- rarely 2-3-fl.: lvs. pinnately cut, lobes 3-lobed, incisely many-cleft: sepals glabrous; petals 8-10, white, sometimes suffused with yellow toward the base, oblong, claw orange: achenes obliquely ovate, reticulate-rugose, emarginate; beak short and curved. May-Aug. Alpine Eu. and Siberia.

14. *amplexicaulis*, Linn. Perennial, 3-12 in. high: sts. erect, glabrous, with 2-3 flowering branches: lvs. oval-lanceolate, acuminate, amplexicaul, at first with hairy edges soon becoming glabrous, glaucous: fls.

3-6, terminal or axillary, pure white, with yellow stamens; sepals acute; petals much larger, obtuse: achenes in an ovoid head, obliquely globose, faces raised in prominent nerves, beak recurved; receptacle pubescent at base. April-July. Mountains of Eu. B.M. 266 (poor). L.B.C. 16:1593. J.H. III. 35:345; 71:85. G.C. II. 19:788. G.L. 22:95. G.W. 3, p. 217; 15, p. 429.

15. *pyrenæus*, Linn., also incorrectly offered in the trade as *pyrenæicus*, Hort. Perennial, about 1 ft. high: lvs. linear or lanceolate, entire, all basal, bluish green: scape tomentose at the top, 1-4-fld.; fls. white, rather large; sepals glabrous; petals obovate: achenes obliquely obovate-globose, sides glossy, beak short, hooked; receptacle pubescent. June-Aug. S. Eu.

16. *parnassifolius*, Linn. Perennial, 3-8 in. high: sts. 1-6-fld., hirsute above: radical lvs. long-petioled, rather cordate or ovate-rounded, upper surface shiny

3342. *Ranunculus lingua*. ($\times \frac{1}{4}$)

green, under surface lanate on the nerves; petioles lanate; cauline lvs. sessile, ovate-lanceolate: fls. snowy white or rarely purplish; sepals pubescent, roseate, very obtuse; petals obovate: achenes in a spherical head, obliquely globose, faces glossy; receptacle pubescent. June, July. Alps and Pyrenees. B.M. 386. L.B.C. 3:245. J.H. III. 30:37. Gn.W. 20:275.

17. *insignis*, Hook. f. Perennial, 1-3 ft. high, usually villous: sts. stout and erect; paniculately branched: radical lvs. numerous, large, rounded-cordate or reniform-crenate, often short-lobed, 4-9 in. diam., thick and leathery; petioles stout, sheathing at base; cauline lvs. smaller, upper cut and lobed: peduncles often very numerous, stout with linear-oblong bracts: fls. golden yellow, 1-2 in. across; sepals 5, woolly outside; petals 5-6, rarely more, obcordate, with 1 or 2 glands at base: achenes forming a rounded head $\frac{1}{2}$ in. diam., swollen, villous, beak long and slender; receptacle oblong, pubescent. New Zeal.—A variable plant, both in size and degree of hairiness.

18. *gramineus*, Linn. (*S. graminifolius*, Salisb.). Perennial, 6-12 in. high: sts. erect, fibrillose at the neck, otherwise glabrous, 1-7-fld.: lvs. lanceolate or linear, entire: fls. yellow, brilliant; sepals glabrous; petals cuneate, scales of the petals tubular: achenes in a head, obliquely obovate-globose, faces reticulate, nerved, beak short; receptacle glabrous. April-June. Eu. and Morocco. B.M. 164.

19. *lingua*, Linn. Fig. 3342. Perennial, 2-3 ft. or more high: roots densely fibrous: sts. erect, glabrous: lvs. 6-10 in. long, lanceolate, acuminate, sessile, semi-amplexicaul, entire or toothed: fls. showy, yellow, about $1\frac{1}{2}$ in. across, somewhat paniced; sepals oval, villous; petals shining: achenes 60-80, in a globose head, compressed, with a straight border which is larger at the top, beak large, short, sword-shaped; receptacle glabrous. June-Sept. Marshes, ditches and pond borders. Eu. and Temp. Asia south to the Himalayas. Gn. 48:500.—Useful for water-gardens and aquatic planting. Var. *grandiflorus*, Hort., apparently differs only in the size of fl.

20. *repens*, Linn. Perennial, stoloniferous: root-stock short and thick; roots fibrous: sts. decumbent, 8 in. to 2 ft. long, more or less appressed hairy: lvs. 3-divided, the terminal segm. or all three petioluled, all ovate, cuneate or truncate, acute, incised-lobed: peduncles sulcate: fls. yellow, about 1 in. across; sepals spreading, hairy below; petals obovate, much longer than the sepals: achenes in a globose head, plano-compressed, ovate-orbicular, beak slightly curved less than half the length of the body; receptacle slightly villous. May-July. Eu., Siberia, N. Amer., Newfoundland to Va., Ont. and Brit. Col., Bermuda and Jamaica. B.B. (ed. 2) 2:113. Var. *flore-pleno*, DC., Fig. 3343, is a double form not uncommon in gardens.

21. *bulbosus*, Linn. (*R. speciosus*, Hort.). Perennial, about 1 ft. high: root a true bulb: sts. erect, hirsute: lvs. petioled, broad ovate, 3-5-parted, terminal division petioluled, lateral sessile or nearly so, all variously lobed or cleft: peduncles sulcate: fls. bright yellow, about 1 in. across, terminating the branches; sepals often reflexed; petals 5-7, much larger than the sepals, obovate, shining above: achenes in a globose head, ovate, compressed, beak very short, bowed; receptacle slightly villous. Eu., Persia, N. Afr., naturalized in N. Amer., New England to N. C., Tenn., and La. B.B. (ed. 2) 2:112.—One of the common field buttercups. Var. *flore-pleno*, Hort. (*R. speciosus flore-pleno*, Hort. *R. speciosus plenus*, Hort.), is a double-fl. form.

22. *Enysii*, T. Kirk. Perennial, 6-15 in. high: root-stock rather stout: sts. slender, glabrous: lvs. all radical, numerous, 1-3 in. diam., 3-5-foliate or biternate; lfts. long-petioluled, toothed, 3-5-lobed or 3-5 narrow cuneate incised, toothed or lobed segms., occasionally pinnately divided: scapes 1-5, longer than the lvs., 1- rarely 2-fld.: fls. yellow, $\frac{1}{2}$ -1 in. across; sepals 5, broadly ovate; petals usually 5, rarely more, broadly obovate: achenes in a small rounded head, numerous, turgid, glabrous, beak stout, straight or curved. New Zeal.

23. *montanus*, Willd. Perennial, about 6 in. high: rootstock short, creeping: sts. pubescent, with soft appressed or spreading hairs, especially toward the top, usually 1-fld.: radical lvs. few, petioled, glabrous, orbicular or pentagonal, palmately 3-parted, segms. obovate, trifid, obtuse, sinus sharp; cauline lvs. 3-5-parted, sessile, somewhat clasping, segms. linear-oblong, divergent, obtuse: fls. bright yellow, terminal, about 1 in. or more across; sepals pubescent, concave, acute, yellowish green; petals 5, large, broadly obovate with a very short scale at base: achenes 20-30, turgid, glabrous, beak recurved, much shorter than the body; receptacle pilose. May-July. Mountains of Eu. B.M. 3022. L.B.C. 17:1610. G. 37:341. Var. *dentatus*, Baumg. (*R. carpaticus*, Herbach). Lvs. much more

toothed than in the type: plant much taller: fls. larger. B.M. 7266. Gn. 52:262.

24. *polyanthemos*, Linn. Perennial: sts. erect, many-fl., spreading, pilose: radical lvs. broadly ovate-orbicular, palmately 3-5-parted, segms. linear, dentate; petioles spreading, pilose: peduncles sulcate: fls. yellow; sepals villous: achenes prolonged into a very short, somewhat hooked beak. N. and Cent. Eu., Caucasus region.—The common form in cult. is var. *plenus*, Hort., which has a branching infl. of small globular orange fls.

25. *californicus*, Benth. Perennial, 6-25 in. high, pubescent or hirsute: sts. rather weak, branching and naked above: lvs. ternately divided or parted, some pinnately 5-divided, segms. linear or narrow-lanceolate and often 2-3-parted: fls. yellow; sepals closely reflexed; petals 6-15, glossy, oblong or narrowly obovate, $\frac{1}{8}$ - $\frac{1}{2}$ in. long: achenes flattened, only slightly margined, beak short, stout, and closely recurved. Dry ground, Calif. and Ore.—The common species of that region.

26. *acris*, Linn., also spelled *acer* by some recent authors. Fig. 3344. Perennial, 8 in. to 3 ft. high: sts. erect, pubescent, many-fl.: radical lvs. tufted, petioled, palmately 3-7-parted, divisions sessile and cleft; cauline lvs. similar, petioles shorter and sheathing the st.; uppermost only 3-parted, lobes entire, nearly linear: fls. golden yellow, about 1 in. across; sepals spreading, ovate, villous beneath; petals 5, glabrous, glossy, obovoid, obtuse, bearing a prominent scale at the base, much longer than the sepals: achenes in a globose head, coriaceous on the margins, compressed, beak less than half the length of the body. April-Sept. Eu. and naturalized in N. Amer., Newfoundland, Canada and the Atlantic states. B.B. (ed. 2) 2:111. Var. *flöre-pleno*, Hort. (*R. acer flöre-pleno*, Hort.), is a double form which is more common in cult. The most desirable forms are rich glossy golden yellow and very double; known horticulturally as "yellow bachelor's buttons." B.M. 215.

27. *lanuginosus*, Linn. Perennial, villous: sts. tall, erect, many-fl., hairs reflex or spreading, fibrillose at the neck: radical lvs. broadly orbicular-pentagonal, silky pubescent, 3-parted, divisions broad-obovate, acutely trifid and dentate; petioles with hairs reflex or spreading: peduncles striate: fls. yellow; sepals spreading, villous: achenes plano-compressed, obovate, marginate, beak one-third as long as the body, hooked; receptacle glabrous. July. Eu. and Caucasus region. Var. *flöre-pleno*, Hort., is a double form, which is the one usually cult.

28. *constantinopolitanus*, Urv. Perennial: sts. erect, retrorse villous, corymbosely many-fl.: lvs.

long-petioled, appressed, silky, broadly triangular-ovate, trifid or 3-parted, divisions ovate, acutely lobed and dentate; petioles retrorse villous: peduncles terete: fls. yellow; sepals reflexed: achenes plano-compressed, suborbicular, marginate, beak one-third to one-fourth as long as the body, coiled to hooked, rising abruptly.

3344. Buttercups.—*Ranunculus acris*. (Natural size)

Turkey. Var. *palæstinus*, Boiss. (*R. palæstinus*, Boiss.). Lvs. 3-parted, divisions divergent from the base, cuneate-oblong, 2-3-cleft. Palestine and Syria. There

is a form of this known horticulturally as *R. palæstinus atrocarcinus*, with large intense scarlet fls., borne on long peduncles. Palestine.

29. *anemonefolius*, DC. Perennial, scarcely 1 ft. high: sts. erect, 1-2-fl., somewhat fibrillose at the neck otherwise glabrous below, appressed-pubescent above: radical lvs. pubescent, broadly orbiculate, sometimes 3 in. diam., 3-parted, divisions cuneate, deeply trifid, segms. acute, dentate; cauline lvs. few, divided into

linear segms.: fls. large, yellow; peduncles finally striate: young achenes obovate, compressed, beak hooked, one-sixth the length of the body. Asia Minor.

R. adoneus, Gray, 4-12 in.: shaggy-hairy: sts. more or less decumbent: fls. golden yellow. Colo.—*R. anemonoides*, Zahl., 6 in.: fls. white or tinged rose. Austria. Gn. 22:252. J.H. III. 54:345.—*R. aquatilis*, Linn., sometimes called lodewort, ram's foot, etc., is an interesting aquatic plant common in temperate regions, the floating lvs. often broad and 3-lobed, while the submerged lvs. are cut up into numerous thread-like segms.—*R. Arénsis*, Hort. (*R. amplexicaulis* $\times$ *R. gramineus*), has fls. of a soft shade of butter-yellow, fading white, and likes partial shade and a moist situation, according to trade-lists.—*R. bullatus*, Linn., is a yellow-fl. species offered in single and double forms by Dutch bulb-dealers. Medit. region.—*R. cardiophyllus*, Hook., offered in Colo. in 1900, is considered by Gray as *R. affinis* var. *validus*. It is an American species pictured in B.M. 2999 with yellow fls. $1\frac{1}{4}$ in. across.—*R. fascicularis*, Muhl. Height 1 ft. June. N. Amer. Mn. 2:1.—*R. Lyallii*, Hook. f., the New Zealand water-lily, grows 2-4 ft. high, has peltate lvs. and waxy white fls. 4 in. across, borne in many-fl. panicles. In Eu. it is considered a cool greenhouse plant. It is a gorgeous species and ought to succeed somewhere in N. Amer. G.C. II. 15:724; 23:371; III. 51:suppl. June 29. Gn. 67, p. 23; 74, p. 379.—*R. pedatus*, Waldst. & Kit., a native of the Hungarian Alps, has yellow fls. nearly an inch across.—*R. septentrionalis*, Poir., has been listed; a native plant allied to *R. repens*.—*R. spectabilis plenus*, Hort., has been offered as a dwarf plant with double shining yellow fls. This species is unknown botanically.—*R. spicatus*, Desf., is figured in B.M. 4585 with showy 5-petaled yellow fls. fully 2 in. across. It is an Algerian species but is said to be perfectly hardy in England and of easy cult. in any good garden soil. J.F. 2:143.—*R. Süksdorfii*, Gray. 4-10 in.: st. slender, 1-3-fl.: fls. deep yellow. Mountains Wash., Ore. and Mont.—*R. superbissimus*, Hort., is used in some catalogues for the double French ranunculi, known also as *R. asiaticus* var. *superbissimus* (No. 7).—*R. viridiflorus*, Hort. Van Tubergen, is a scarlet-and-green-fl. variety of the Turban class of *R. asiaticus*.

F. TRACY HUBBARD.

RAPE (*Brassica Napus*). Fig. 3345. In recent years rape has become an important forage plant. The name rape includes several varieties which are grown for two purposes: (1) for seed from which oil is expressed

3343. *Ranunculus repens*, double-flowered. Tip of a decumbent plant, which roots at the joints. ($\times \frac{1}{2}$)

(2) for the purpose of furnishing animals with succulent feed during late summer and autumn, when pastures become bare. Varieties used for the latter purpose usually do not produce seed in this climate the same season, though they are usually classed with annuals. Dwarf Essex is an example of the kind used for soiling (green feeding) purposes. Rape is of considerable importance to the fruit-grower as a cover-crop. The seed germinates readily, will often grow where a clover catch is impossible, and furnishes excellent sheep pasturage late in the season. When grown strictly as a

3345. Dwarf Essex rape. ($\times \frac{1}{12}$)

soiling plant, the tops are cut and hauled to the feed-lot or stable. Dwarf Essex rape much resembles a rutabaga turnip at first. It is like a rutabaga with an exaggerated leafy top and without a swollen fleshy root. Rape is a cool-weather plant and may be grown in almost any part of the United States by sowing it at the proper time. As a cover-crop in the orchard in the East it may be sown as late as September 15 with good results. It is an excellent pioneer plant in the work of renewing humus in worn-out lands. In the Middle West, where shade is needed, rape is used as a nurse plant for clover when the latter is sown in orchards in midsummer. Turnips may be used for the same purpose.

JOHN CRAIG.

RÁPHANUS (classical name, from the Greek). Sometimes spelled *Rhaphanus*. *Cruciferae*. Annual or biennial branching herbs, one of which, *R. sativus*, is the radish (which see).

Leaves various and variable, the radical and sometimes the cauline lyrate-pinnatifid; fls. small but rather showy, slender-pedicelled, in open terminal racemes, rose-lilac or white, or in some species yellow; sepals erect, the lateral ones somewhat saccate or pouch-like at base; stamens 6, free; pod a long-cylindrical fleshy or soft-corky silique, with spongy tissue between the globose seeds, indehiscent.—About 10 species in Eu. and Temp. Asia. The genus is divided into two natural groups, one (*Raphanistrum*) with the pod longitudinally grooved and constricted between the seeds, the other (*Raphanus* proper) with the pod not grooved nor prominently constricted. To the former group belongs *R. Raphanistrum*, Linn., the JOINTED or WHITE CHARLOCK (sometimes, but erroneously, known as RAPE). It is an Old-World annual weed, now naturalized in fields and waste places in the easternmost states. It is an erect sparsely hairy herb, with slender tap-root and radish-like lvs., growing 2–3½ ft. high; fls. rather showy, yellowish, turning white or purplish; silique 1–3 in. long, few-seeded, with a long beak. It is from this species that Carrière produced radishes by means of plant-breeding (see *Radish*). To the second section belongs *R. sativus*, Linn., the RADISH, considered to be native to Eu. and Asia, but imperfectly known in an aboriginal wild state. It is usually annual, although commonly spoken of as biennial because the roots can be kept over winter and planted the following spring. The winter radishes are truly biennial in northern climates. Radish has pink-lilac or nearly white fls., and short thick spongy taper-pointed pods. Sometimes it runs wild in waste places, and then bears a long hard tap-root like that of *R. Raphanistrum*. The radish is extensively cultivated for its thick root, which has been developed into many shapes and colors. There are Chinese types of radish that have hard roots

little more than 1 in. diam., and sometimes becoming nearly 1 ft. long. Some forms are scarcely distinguishable from short turnips. The Madras radish (India) is grown for its soft tender pods, which are eaten raw or in pickles. The rat-tailed or serpent radish, var. *caudatus* (*R. caudatus*, Linn.), has enormously long pods (see Fig. 3346), which are eaten either pickled, or raw as are radish roots. Frequently the pods are 1 ft. long. The root is slender and hard. This is a cultural variety, coming true from seed.

L. H. B.

RÁPHIA (Greek, *needle*, referring to the fact that the fr. ends in a noticeable point). *Palmææ*. Monocarpic palms unarmed or with the sheaths only armed: sts. erect, simple or dichotomously branched; densely annulate: lvs. in a terminal crown, equally pinnatisect; lfts. linear-lanceolate, acuminate, rachis not produced at the apex; spadices monœcious, large, pendulous, cylindrical, much-branched; the branches and branchlets thick, compressed, the latter pectinately arranged, densely covered with cup-shaped bracts; common spathe none; fls. solitary in each bract, the male at the base of the ultimate branches of the spadix, the female at the apex; calyx tubular, entire or minutely toothed; corolla curved, the petals 3, linear-lanceolate, valvate; stamens 6–16; fr. large, oblong or ellipsoid, rostrate, 1-seeded.—About 15 species, Trop. Afr. and the Mascarene Isls., 1 in Trop. Amer. *R. Gentiliana*, Wildem. Lvs. pinnate, furnished with small prickles: infl. dense, pendent, nearly 3 ft. long with flattened branches, the principal rachis of the branches with imbricate bracts: fr. pyriform, apiculate, 2–2½ in. long, with 9–10 rows of fringed scales. Congo. *R. Laurentii*, Wildem. Trunk up to 6 ft.: lvs. 15–40 ft. long; rachis subcylindrical, about 3 in. thick, grooved; lfts. irregularly disposed, linear, up to 5½ ft. long and 2 in. broad, acute, with short blackish spines: infl. compact, branched, more than 3 ft. long; fr. ovoid, about 2 in. long, short-peduncled, with 12 rows of scales. Congo. R. B. 32, pp. 14–16. *R. Rüffia*, Mart. **RAFFIA** or **ROFFIA PALM**. Trunk 6–26 ft. high: lvs. up to 65 ft. long, petiole up to 13 ft. long, nearly 1 in. thick: fr. obovate or pyriform, somewhat depressed and mucronate at the apex, 12–15 rows of very convex scales. Trop. Afr. and Madagascar. *R. tædigeræ*, Mart. Trunk 6–8 ft. high: lvs. 50 ft. or more long, bending out and often forming a graceful plume 70 ft. high and 40 ft. diam.: fr. oblong, 2½ in. long, reticulated with large scales. Amazon. Probably also produces raffia. *R. vinifera*, Beauv. **BAMBOO** or **WINE PALM**. Trunk of medium

3346. Rat-tailed radish.—*Raphanus sativus* var. *caudatus*. Grown for its enormous pods. ($\times \frac{1}{16}$)

height: lvs. 6-7 ft. long; lfts. spiny: spadix about 8 ft. long, laxly branched: fr. cylindric-ellipsoid, shortly mucronate, 3 in. long, 8-9 rows of deeply grooved scales. Trop. Afr.—The natives make wine from the sap of the trunk and which they call "bourdon."

F. TRACY HUBBARD.

RAPHIÓLEPIS (Greek, *raphis*, needle, and *lepis*, scale; referring to the subulate bracts). Sometimes spelled *Rhaphiolepis*. *Rosaceæ*, subfamily *Pomeæ*. Ornamental shrubs grown for their handsome foliage and attractive white or pinkish flowers.

Leaves persistent, alternate, short-petioled, serrate, rarely entire: fls. in terminal racemes or panicles; sepals triangular; petals 5, oblong or obovate; stamens 15-20; ovary completely inferior; styles 2-3, connate toward the base: fr. subglobose, purplish black or bluish black with 1 large subglobose or 2 partly compressed seeds.—Two or perhaps 4 species in S. Japan and China.

These are handsome evergreen shrubs with alternate or obscurely whorled leaves, white or slightly pinkish flowers and small pea-sized black fruits. None of the species is hardy North, but *R. umbellata* will stand about 10° of frost or even more with some protection; they are well suited for cultivation in the southern states and California. They will thrive in any good well-drained soil, and if cultivated in pots, a compost of sandy loam and leaf-mold or peat will suit them. Propagation is by seeds or by cuttings of ripened wood under glass late in summer; also by layers, and sometimes grafted on hawthorn.

umbellata, Schneid. (*R. japonica*, Sieb. & Zucc.). Shrub, to 12 ft., with stout upright branches: lvs. short-petioled, elliptic to broadly oval or obovate, obtuse or acutish, narrowed at the base, crenate-serrate, dark green and lustrous above, pale beneath, floccose-tomentose when young, thick, 1½-3 in. long: fls. white, ¾ in. across, fragrant, in dense, tomentose panicles or racemes; petals obovate, obtuse: fr. to ½ in. across. May, June. S. Japan and adjacent islands. S.Z. 1:85. Gn. 22, p. 43; 32, p. 20; 34, p. 158. G. 7:165; 10:224. Var. *ovata*, Schneid. (*R. ovata*, Briot). Lvs. broadly obovate, rounded at the apex. R.H. 1870, p. 348. G.W. 4, p. 129; 14, p. 323. J.H. III. 47:521; 69:81. Var. *integerrima*, Rehd. (*R. japonica* var. *integerrima*, Hook.). Lvs. entire or nearly so, broadly obovate. B.M. 5510.

indica, Lindl. (*R. rubra*, Lindl. *Cratægus indica*, Linn.). INDIAN HAWTHORN. Shrub, to 5 ft., with slender spreading branches: lvs. obovate to oblong-lanceolate, acute or acuminate, gradually narrowed at the base, serrate, glabrous or slightly pubescent when unfolding, 1½-2½ in. long: fls. white or pinkish, about ½ in. across, in glabrous or somewhat tomentose, rather loose panicles; sepals lanceolate, acute, usually red like the filaments; petals acute: fr. ¼-½ in. across. May, June. S. China. B.M. 1726. B.R. 1468; 1400 (as *R. rubra*). L.D. 4:247 (as *Cratægus sinensis*).—A very variable species; several forms have been described as distinct species, as *R. Phæostemon*, *R. rubra* and *R. salicifolia*, Lindl. The last named, which is var. *salicifolia*, Nichols., is the most ornamental: lvs. oblong-lanceolate, acuminate; panicles rather large and many-flid.; stamens white or purplish, shorter than sepals. B.R. 652. R.H. 1874:270. Gn. 9:596.—A hybrid between *R. indica* and the preceding species is *R. Delacourii*, André, forming a compact shrub with rather large panicles of blushed fls. and the foliage intermediate between the two parents. R.H. 1900:698.

ALFRED REHDER.

RAPHIONÁCME (Greek, *needle* and *point*, referring to the 5 pointed or awned scales in the throat of the corona). *Asclepiadaceæ*. Herbs, with tuberous rootstock often furnished with an elongated woody neck; juice milky; lvs. opposite: fls. small or moderate-sized,

terminal in few- or many-flid. cymes, or in the forks of the st., or subaxillary from one axil, rarely from both; calyx 5-parted; corolla-tube distinct, campanulate, lobes 5, erect, spreading or reflexed; crown of 5 free, entire, 2-3-divided or 3-parted lobes alternating with the corolla-lobes: follicles often solitary by abortion.—About 35 species, Trop. and S. Afr. *R. utilis*, N.E. Br. & Stapf. Perennial herb with a turnip-shaped tuber 2-5 in. diam., covered with dark brown flaky bark: sts. annual, 1-4 in. long, erect or decumbent: lvs. in 2-5 pairs, opposite or forming a rosette close to the ground, orbicular, elliptic or oblong-ovate, obtuse and apiculate or subacute at the apex, rounded or subcordate at base, green above, purple beneath: fls. in small terminal and axillary cymes or clusters, bright purple; sepals lanceolate, acute, purplish with green tips; corolla about ½ in. diam., deeply 5-lobed. Trop. Afr. B.M. 8221.

F. TRACY HUBBARD.

RAPHIS: *Rhaphis*.

RAPHISTÉMMMA (Greek, *needle* and *crown*, referring to the linear scales of the crown). Glabrous twining shrubs: lvs. opposite and membranaceous: infl. long-peduncled, axillary, umbelliform cymes; fls. large, white, and long-pedicelled; calyx 5-glandular inside; corolla campanulate, 5-cleft, lobes spreading, twisted in bud and overlapping to the right; crown with 5 membranaceous scales which are produced into long slender linear ligules: follicles thick, acute, smooth.—About 2 species, Asia. *R. pulchellum*, Wall. Branches slender, smooth, and herbaceous: lvs. cordate-acuminate, 3-7 in. long: cymes 4-6-flid.; the pedicels very slender: fls. pure white, 1-1½ in. long; sepals broad; corolla thick. Himalaya region and Burma. J.F. 4:353.

RASPBERRY (from *rasp*, a tool resembling a file, and berry), a name applied to certain species of the genus *Rubus*, particularly to *Rubus idæus*, *R. strigosus*, and *R. occidentalis*, from which have been derived common cultivated forms grown for their excellent edible fruits.

Raspberry plants have perennial roots and erect or nearly erect biennial canes bearing thimble-shaped red, yellow, black, or purple-colored fruit consisting of many cohering drupelets which separate from a partially dried receptacle. The raspberry is distinguished from the blackberries and dewberries, which belong to the same genus, in bearing fruit that separates from its receptacle, while that of the blackberries and dewberries does not separate from their juicy receptacles.

Origin of horticultural varieties.

The first raspberries introduced into cultivation in America were varieties of European origin belonging to the species *Rubus idæus*. These varieties, adapted to a mild humid climate, did not prove sufficiently hardy to merit their continued cultivation after hardy native varieties of good quality began to be propagated. At present but two varieties, the Antwerp and Superlative, representing the European species, *Rubus idæus*, are grown commercially. These two varieties are raised only in the Pacific Coast region and are there being gradually superseded by American varieties.

By far the greater part of the varieties under cultivation at present belong to the American species *Rubus strigosus* and *R. occidentalis*. The American red raspberry, *R. strigosus*, is very similar to the European species, *R. idæus*. Both species have erect canes, but the American species has proved much harder and adapted to a wider range of environmental conditions. Two of the first varieties of this species to come under cultivation were the Marlboro and Cuthbert, and these are still two of the most widely grown varieties. The black raspberry, *R. occidentalis*, has recurved canes which are longer than those of either of the red-fruited

species, and bears black fruit. The acreage of this class is, at present, much less than that of the red raspberry. The Gregg, one of the first varieties of this species introduced into cultivation, is also one of the leading varieties grown at present.

Yellow-fruited varieties have come from both the American species, the erect-growing sorts from *R. strigosus*, and those with recurved canes rooting at the tips from *R. occidentalis*. Purple-caned varieties, of which the Columbian is the most widely grown, are hybrids between *R. strigosus* and *R. occidentalis*.

Up to the present time, the greater part of the varieties under cultivation have appeared as chance seedlings. Recently, however, many promising new varieties have been originated as a result of systematic effort to produce better sorts. Thus, as the result of definite breeding work, the New York State Experiment Station has originated the June red raspberry, and the South Dakota Experiment Station the Ohta and Sunbeam red raspberries. These, as well as other experiment stations, have many promising varieties under test. L. E. Wardell, a practical grower of Marlboro, New York, has originated the Empire red raspberry, another promising variety. Many others are also trying to originate better varieties, some of whom are using in their work foreign species recently introduced into this country.

Geographical distribution.

The limit of the successful culture of this fruit corresponds closely with the distribution of its wild forms. The southern limit is southern Virginia, along the mountains to northern Georgia, southern Tennessee, westward through the Ozark Mountains and southern Oklahoma. It is chiefly grown in northern regions. The great commercial centers of the industry are, at present, in New York State and Michigan. Smaller centers of its culture, aside from the proximity of the large cities, are found near Hagerstown in western Maryland; in central New Jersey; near Kansas City, Kansas; about Loveland, Colorado, and in the Puyallup Valley of Washington. The culture of the raspberry, however, is not confined to these centers, but is widely distributed throughout the northern districts.

Propagation.

The red varieties are propagated by the use of suckers which spring from the underground parts. Nur-

serymen secure their stock by digging in the spring suckers sent up during the previous summer. Some growers who wish to increase their own plantation wait until young suckers begin to come up in the spring and transplant these. The black raspberries, as well as the purple varieties now raised, are propagated by encouraging the tips of the young canes to root. As the young canes bend over and the tips approach the ground, soil is

thrown over the tips. Plants suitable for setting the following spring will be formed during the remainder of the growing period by these rooted tips. By pinching back the tips in early summer when the canes are about 2 feet high, they will branch and several plants may be secured from each cane.

Culture.

The raspberry thrives best in a deep fertile loam containing plenty of humus. Most varieties grow better on the heavier than on the lighter types of soil, though this is not universally true. The soil must be well drained and a location with good air-drainage should be preferred to lowlands, as certain varieties are peculiarly susceptible to poor air-drainage. Fertilizers are not generally used on raspberry fields, and among growers using them their composition varies widely. The use of fertilizers should depend on the needs of the particular soil, and such needs can be determined only by actual tests of the soil with varying amounts and kinds of plant-foods.

Two methods of culture are commonly used, the hill system and the solid-row system. Under the first system the plants are usually set 5 feet apart each way, while under the second system they are set 3 or 4 feet apart in the row, the rows being from 6 to 8 feet apart. Under the hill system less hand-labor is required for the returns in fruit than under the solid-row system.

The plants should be set as early in the spring as possible, as the moisture conditions are usually better in early spring. In setting the plants, the principal requirement is that the soil shall be thoroughly firmed about the roots. Vegetable intercrops may be grown between the rows during the

first season and should help pay the cost of cultivation for the first year. Cabbage, cauliflower, beans, peas, and lettuce are often used for this purpose. Cultivation should be thorough and frequent, not only the first year, but after the plantation comes into bearing. Especially when the berries are growing

3347. Raspberries trained to the hill system.

3348. Raspberries trained to the solid-row system. No support used.

3349. Raspberries trained to a single wire trellis.

3350. Raspberries trained to the two-wire trellis.—Canes in erect position.

3351. Raspberries trained to the two-wire trellis. Canes arched over upper wire and tied to lower wire.

3352. Raspberries trained between the two wires of a horizontal trellis.

3353. Raspberries trained between the two wires of a horizontal trellis, one-half of canes tied to the wire on one side and one-half to the wire on the other side.

and ripening do the plants need the large supply of moisture that frequent cultivation conserves.

Training and pruning.

In training the red raspberries when the plants are set by the hill system, a stake is usually placed by each plant before the second year's growth begins and the year-old canes tied to it (Fig. 3347). This allows the new canes to grow up outside the old ones and makes picking easier. When the solid-row system is used, several methods of training are practised. (1) When the plants are vigorous but do not grow very tall, the suckers are allowed to grow up between the plants in the row, while those between the rows are destroyed by frequent cultivation (Fig. 3348). No pruning is required. (2) When the canes grow very long, they are not pruned until spring and then are sometimes cut back to a height of about 3 feet in order that the cane may support its crop of fruit. Weaker canes are removed at this time. (3) Instead of cutting the canes back as described above, they are often trained to trellises in the following ways: (a) A trellis is made by stretching a wire on posts set about 30 feet apart in the row. The old canes are tied to this wire to keep them upright when ripening their fruit (Fig. 3349). Two wires, one above the other, are sometimes used in making this kind of trellis and the canes either tied in an erect position to both wires (Fig. 3350), or they are arched over the upper wire and tied to the lower (Fig. 3351). When tied in an erect position, those portions of the canes projecting more than 6 inches above the wire are pruned off. (b) The trellis is often made by stretching two wires along the line of posts from the ends of crosspieces about 15 inches in length (Fig. 3352). The old and new canes are kept between the wires and out of the way when the cultivating is done. Sometimes the old canes are tied to the wires, half of them being tied to the wire on one side and half to the wire on the other side (Fig. 3353). The young canes then come up between the old canes and will be out of the way of pickers and cultivators. Many variations of the above systems are in use.

3354. Crate of Cuthbert red raspberries.

The above systems are applicable to the red raspberries. The black and purple varieties do not sucker and are usually trained as follows: The tips of the young canes are pinched back when they are about 2½ feet from the ground. This causes them to branch and form bushes better able to support a heavy crop of fruit. If the side branches grow very long, they are pruned back in the spring to a length of 6 to 18 inches. Sometimes a trellis is made and they are trained on the system

described above under (a).

The old fruiting canes of all types of raspberries should be cut out and taken from the field immediately after the crop is picked. Some fruit is usually secured the second year after planting, often enough to pay the entire cost of cultivation for that year. The duration of the plantation depends on the varieties, the care, the locality, and the practice of the grower.

Some growers of the black raspberries harvest one

3355. Cuthbert raspberry—to show habit of fruit-bearing. (×¼)

crop and then plow the plantation up; most persons keep the fields for two or three crops, and still others gather six to eight crops before destroying the plantation. The red raspberry fields are usually fruited longer than are those of the black raspberry. Growers generally plan to secure eight to ten crops from a field.

Yields from fields receiving good

treatment will vary from 50 to 150 bushels to the acre, depending upon the locality, the soil, and the variety grown.

In many northern and western sections, varieties are grown that require winter protection. This is best secured by drawing the soil from one side of the row of plants, using either hoes or a plow, inclining the canes to that side, and covering them entirely with earth about 2 inches deep. The canes are left as late as possible in the spring before uncovering. When the buds begin to start, the canes are forced into an erect position.

Picking and handling.

Raspberries should be harvested as carefully as possible in order to avoid injuring them. The subsequent behavior of the berries on the market depends in a large measure on the care used in picking and handling. Berries injured or bruised in handling, or soft from being over-ripe, or from rainy weather, are quickly attacked by certain mold fungi which cause their decay. To avoid as much injury as possible, three fingers should always be used in picking; very few berries should be held in the hand at one time, to avoid mashing them; the berries should always be placed, not dropped, into the basket or cup; all decaying, over-ripe, and injured berries should be discarded and no later handling of the berries in the baskets allowed. The crates should be hauled on spring wagons to avoid jolting and neither the berries nor the crates containing them should be exposed to the sun. Pint baskets should be used in harvesting red varieties and either pint or quart baskets for the black and purple varieties. (Fig. 3354.) In Pacific Coast regions a basket, or "cup" as it is called there, holding a pound of berries, is commonly employed.

Varieties.

The principal red varieties grown at present are Cuthbert (Fig. 3355). Herbert, King, Marlboro, Ranere (St. Regis), and Perfection (Fig. 3356). Promising new varieties are June, Empire, Sunbeam, and Ohta. Much interest has recently been shown in the fall-bearing type represented by the Ranere.

3356. Perfection raspberry trained to stakes 5 by 5 feet apart.

Among the black raspberries, the Cumberland, Farmer, Gregg, and Kansas are the leading varieties. The Golden Queen is the principal yellow sort grown. The Columbian is the principal purple-caned variety at present, although the Shaffer (Fig. 3357) and Cardinal are also grown. The Royal is a very promising new purple-caned sort.

Enemies.

Among the more serious diseases of the raspberry are crown-gall, anthracnose, cane-blight, and orange-rust. When plants free from these diseases are set, very little trouble is likely to be experienced later from them. The means of control commonly employed when these diseases are found are eradication and destruction of plants affected by crown-gall and orange-rust, and the cutting out and removing from the field of all canes affected by anthracnose and cane-blight. Cane-borers are considered the most serious insect enemy of the raspberry. The adults lay their eggs in the tips of the canes. When these tips are seen to be withering and drooping, they should be cut off and burned. If the cut is made well below the point of injury, these tips will contain the eggs or young larvæ of the borer.

GEORGE M. DARROW.

RATHBUNIA (named for Richard Rathbun, Assistant Secretary in charge of U. S. National Museum). *Cactaceæ*. Plants not large, the st. and branches often weak; spines stout, those of the flowering areoles not differing from the others: fls. diurnal, single, only from the upper areoles, very narrow and elongated, at first straight, but in age more or less curved, oblique at throat, scarlet, persistent; petals very short, spreading or reflexed; stamens attached near the middle of the tube, exserted: fr. spiny, globular, red, breaking open irregularly; pulp red; seeds black, compressed, minutely pitted, with a large basal oblique hilum.—Three species have been described. Native of the west coast of Mex. The species all have rather weak sts., often clambering and resembling somewhat *Cereus serpentinus*, but usually stouter and with different spines and fls. The fls. are very narrow and scarlet, and more enduring.

alamosensis, Brit. & Rose (*Cereus alamosensis*, Coult.). Upright, columnar, about 4 ft. high by 2 in. diam.: ribs 7-9; spines numerous, stout; central spines usually 4: fls. from the upper areoles, funneliform, about 1½ in. long, red. W. Mex.

R. sonorensis, Brit. & Rose, and **R. Kerberi**, Brit. & Rose, are sometimes confused with the above, and may be handled under this name in the trade.

J. N. ROSE.

RAUWOLFIA (named for Leonhart Rauwolf, a physician of Augsburg in the sixteenth century). *Apocynaceæ*. Trees or shrubs, mostly glabrous, sparingly grown, suitable for the warmhouse and outdoor planting in the far southern parts of the United States.

Leaves opposite or verticillate, those of a whorl often very unequal: infl. terminal or pseudo-axillary, peduncled, few- or many-fld., compound, umbelliform or corymbose, rarely racemose; fls. small; sepals 5, almost free or united into a flat 5-toothed cup; corolla salver-shaped, lobes 5, twisted and overlapping to the left; disk annular or cup-shaped, entire or slightly lobed; carpels 2, free or more or less coherent: drupes 2, distinct or somewhat united.—About 60 species from the tropics of both hemispheres.

chinensis, Hemsl. A small evergreen shrub, with dark green lvs., white fls. which are borne in dense terminal trusses, and numerous red berries. China.—Intro. into Orange Co., Fla., as an ornamental, where it is semi-hardy, but always sends up strong new shoots in the spring. Requires a light rich soil and plenty of water, with some protection against the sun. Each spring, it should receive fresh rich compost.

pleiosciadica, K. Schum. A shrub or small tree, up to 20 ft. high: lvs. in whorls of 3 or 4, lanceolate to elliptic, 3-7 in. long: fls. in cymes, arranged in umbels, white; corolla-tube 3-3½ in. long. Trop. Afr.

F. TRACY HUBBARD.

RAVENALA (the name of the plant in Madagascar). *Musaceæ*. Musa-like plants becoming 20 to 30 feet high, with a palm-like trunk, cultivated for ornamental uses.

Leaves exceedingly large, crowded in 2 ranks, thus forming a fan-shaped head of foliage; petioles long, with concave bases scarcely sheathed: scapes or peduncles in the upper axils longer or shorter than the lvs.: bracts spathe-like, many, boat-shaped, acuminate: fls. many, large, in a spathe or bract; petals long-exserted; sepals free: fr. a 3-valved caps.—A genus of 2 species, 1 from Madagascar and the other from Brazil and Guiana.

A. Lvs. shorter than petioles.

madagascariensis, J. F. Gmel. **TRAVELERS' TREE**, so called from the clear watery sap in the large box-like cells of the lf.-stalks or caught in the lf.-sheaths, and which affords a refreshing drink. Fig. 3358. Lvs. often 30 ft. high, very large, fibrous: fls. white, in spathe about 7 in. long. Gng. 5:153. V. 23, p. 136. F.S. 21:2254. A.F. 12:535. R.H. 1890, p. 152. G.C. III. 2:693; 50:460. A.G. 20:870.—Cult. in Fla. and S.

3357. Shaffer raspberry.—*Rubus neglectus*. (×¼)

Calif.; also rarely under glass in the northern states. It is said that in S. Calif. the traveler's tree was never really successful.

AA. *Lvs. as long as the petioles.*

guyanensis, Steud. Becoming 15 ft. high: lvs. oval-elongated: fls. white; spathes 1-1½ ft. long.—Offered 1893 in S. Fla.

F. W. BARCLAY.

RAVENIA (name not explained). *Rutaceæ*. Tender glabrous shrubs suitable for the warmhouse.

Leaves opposite, 1-3-foliolate; lfts. lanceolate, entire: fls. red or white, borne on rather long axillary peduncles; sepals unequal, the 2 outer being somewhat foliaceous; corolla-tube straight, rather long; the limb nearly regular.—Two species from Cuba and Brazil.

spectabilis, Griseb. (*Lemônia spectabilis*, Lindl.). Tender shrub: lfts. 3: fls. purplish red, about 1 in. across, solitary or in open, few-fl. clusters on axillary peduncles as long as the lvs. Cuba. B.R. 26:59. R.H. 1844:25.—The plant once offered in Fla. as *Lemônia spectabilis* apparently is of some other genus. F. W. BARCLAY.

REBUTIA (named for Rebut). *Cactaceæ*. Plants very small, globular, covered with small tubercles, resembling in habit very much a mammillaria: fl. appearing from the side and even the base of plant, large in comparison with the plant, red or orange-colored, with slender, funnel-form tube; bracts on ovary small, naked in their axils: fr. a small berry.—Originally described with 1 species, but a study of S. American material indicates that there may be 5 or 6 other species to be transferred here from other genera. The original species has been referred both to *Echinopsis* and *Echinocactus*, from both of which it is abundantly distinct.

minúscula, Schum. Plants globose, 1-2 in. diam., covered with low tubercles: spines in clusters of 25-30, 1-1½ lines long: fls. often numerous, arising from near the base of plant, 1-1¼ in. long, bright crimson. N. Argentina. B.M. 8583 (as *Echinocactus*).

Fiëbrigii, Brit. & Rose (*Echinocactus Fiebrigii*, Gürke). Globose, depressed at apex, 2 in. diam.: spines 30-40 in a cluster, ½ in. long, white, or some of the longest ones nearly 1 in. long with brownish tips: fls. nearly 1 in. long. Bolivia. Blühende Kakteen, pl. 109.

J. N. ROSE.

RED BAY: *Persea Borbonia*. **Red-Bud:** *Cercis*. **Red Campion:** *Lychnis dioica*. **Red Cedar:** *Juniperus virginiana*. **Redhead:** *Asclepias curassavica*. **Red-hot Poker Plant:** *Kniphofia*. **Red Morocco:** *Adonis autumnalis*. **Red Osier:** *Cornus stolonifera*. **Red Pepper:** *Capsicum*. **Red Robin:** *Geranium Robertianum*. **Red-root:** *Ceanothus americanus*; *Lachnanthes*. **Red-Spider:** See *Diseases and Insects*. **Redtop:** *Agrostis*. **Redwood:** *Sequoia*; also *Ceanothus*, *Pterocarpus*.

REED: *Arundo* and *Bamboo*. **R. Canary-Grass:** *Phalaris arundinacea*. **R., Indian:** *Canna*. **R. Mace, or Cat-tail:** *Typha*.

REEVÈSIA (after John Reeves, an English resident of Canton, China, who introduced many Chinese plants into England). *Sterculiaceæ*. A genus of 3 species in China and Himalayas. Evergreen trees with alternate, simple, entire lvs. 3-nerved at the base and with white or pink fls. in dense terminal corymbs: calyx funnel-form-campanulate, 4-5-toothed; petals 5, clawed; stamens adnate to the long gynophore, much exceeding the petals, 15, forming a globose head; ovary 5-lobed; stigma sessile: caps. large, woody, septicidally 5-valved, seeds 2 in each cell, compressed, winged. Little known in cult. and adapted only for warmer temperate regions. Prop. probably by cuttings from half-ripened wood. **R. thyrsoides**, Lindl. Evergreen shrub: lvs. ovate-oblong to oblong-lanceolate, glabrous, 2-5 in. long: fls.

creamy white, ½ in. across; gynophore ½-¾ in. long. China. B.R. 1236. B.M. 4199. F.S. 3:206. **R. pubescens**, Mast. Similar to the preceding: lvs. ovate to ovate-oblong, subcordate to broadly cuneate at the base, brownish tomentose beneath, 3-5 in. long: fls. somewhat larger, pink; gynophore 1 in. long. E. Himalaya, S. W. China. Recently intro.

ALFRED REHDER.

REHMANNIA (Jos. Rehmann, 1779-1831). *Scrophulariaceæ*. Perennial viscous-villous herbs suitable for the cool greenhouse, grown for the showy bloom.

Stems leafy, branched from the base, either low, scapiform and almost leafless, or (especially in cult.) tall and few-lvd.: lvs. alternate, obovate or oblong, coarsely

3358. Traveler's tree.—*Ravenala madagascariensis*.

dentate: fls. rather large, borne in terminal racemes and short-pedicelled, brownish purple or pale, the throat intensely colored; calyx ovoid-campanulate, 5-cleft at the top; corolla pilose, slightly incurved, tube rather broadly subventricose, limb obliquely 2-lobed, the lobes spread, the rear or inner one deeply 2-cleft, the front one 3-cleft; stamens 4: caps. broad, partly included in the calyx; seeds numerous.—About 5 species, China and Japan.

angulata, Hemsl. Perennial plant, 1-3 ft. high, glandular-hairy: lvs. pinnately lobed, each side of lf. having either very many marginal teeth, or, if there are a few lobes or large teeth, by these being again toothed; the bracts broadly and abruptly cuneate at the base which is wider than any other part of the blade: corolla smaller than *R. elata*, red with a band of scarlet at the margin of the upper lip and has orange dots inside the lower lip. China. G.C. III. 33:296; 47:104. G. 25:171; 28:211. Gn. 63, p. 317. G.M. 46:290; 51:745. Gn. W. 21:117. Gt. 55:1547. G.W. 9, p. 114; 11, p. 488; 12, p. 362. J.H. III. 46:422; 71:11. R.H. 1905:586. F.S.R. 2:280. F.E. 20:526.—Many of these illustrations are probably of *R. elata*.

Var. *tigrina*, Hort., is said to be a garden hybrid of which *R. angulata* is one of the parents: fls. marked. An interesting form.

Var. *tricolor*, Hort. Fls. at first bright purple, later almost violet-rose, the upper lip shaded with vermillion and the throat whitish, spotted with purple. China.

Briscœi, Hort. (*R. elata* × *R. Henryi*). Intermediate in most characters, dwarfier than the former in having an erect infl. instead of a condensed one: the fls. are intermediate in color and of a soft pink: the lvs. arranged in a rosette are similar in shape to those of *R.*

3359. *Rehmannia elata*. (× 1/4)

Henryi and have the same dark veinings, while they are much more velvety-hairy than those of *R. elata* but less so than those of *R. Henryi*. A garden hybrid. G.C. III. 47:188.

elata, N. E. Br. (*R. angulata*, Hort. not Hemsl.). Fig. 3359. Twice as large as *R. angulata*: lvs. 2-6-lobed on each side, lobes acute, entire; bracts or flowering lvs. long-cuneate at base: corolla slightly larger than *R. angulata*, bright rosy purple on the lips and yellow dotted red in the throat. China. B.M. 8177 (as *R. angulata*).

glutinosa, Libosch. (*R. chinensis*, Fisch. & Mey.). Plant pubescent-hirsute: st. 6-12 in. high, erect and weak: lvs. alternate, obovate, attenuate to a short petiole, remotely and coarsely serrate: fls. axillary and solitary, large, yellowish buff or purplish, purple at the throat and purple-veined; calyx-tube oval, inflated, 5-parted, segms. recurved, ovate; corolla hairy, limb 2-lipped. China. B.M. 3653. B.R. 1960. F.S. 11:1134. G. 28:210.

Henryi, N. E. Br. (*R. Piasézkii*, Hemsl., not Maxim.). Perennial herb, 6-18 in. high, glandular-hairy: lowest

lvs. 3-7 in. long, elliptic-oblong, obtuse, base narrowed to the petiole, crenately toothed, or more or less pinnately lobed and obtusely dentate: fls. axillary; calyx ascending, never nodding, campanulate, lobes spreading, deltoid or deltoid-ovate, obtuse; corolla-tube 1 3/4-2 in. long, pubescent outside, dirty yellow spotted red, limb oblique, 2-lipped, white and pubescent, yellow, red-dotted at the throat, upper lip 2-lobed, lower 3-lobed, all the lobes rounded; ovary ovoid, glabrous. China. B.M. 8302. G.C. III. 47:189. G. 31:343. R.H. 1910, p. 571.

kewensis, Hort. (*R. Henryi* × *R. glutinosa*). Sts. leafy, about 2 ft. high: lvs. petioled, ovate, glossy green, irregularly dentate: fls. 2 in. long, 1 1/2 in. across, the corolla-segms. broad, almost square in outline and toothed, creamy yellow with a dark crimson blotch on the upper segms. A garden hybrid. G.C. III. 51:218. Gn. 76, p. 296. G.M. 55:485. J.H. III. 66:469.

F. TRACY HUBBARD.

RÊIDIA: *Phyllanthus*.

REINÉCKIA (J. Reinecke, a German gardener). *Liliacæ*. A tender perennial herb, with attractive foliage in tufts 1-1 1/2 ft. high from a thick, creeping rootstock: lvs. rather long, channeled: scapes leafless: fls. sessile, in a loose spike; perianth-tube cylindrical; lobes recurved, spreading; ovary 3-loculed, with a few seeds to each cell: berry globular, usually with 1 seed to each cell. A single species from China and Japan. The following is procurable from Dutch bulb-growers. *B. carnea*, Kunth. Fls. dull flesh or pink: bracts rather large, tinted red; fr. red, 3-4 lines diam. Var. *variegata*, Hort., is also offered. I.H. 9:323.

REIN ORCHIS: *Habenaria*.

REINWÁRDZIA (named in honor of Kaspar Georg Karl Reinwardt, 1773-1822, scientist of Leyden). *Linacæ*. Subshrubs, sometimes nearly shrubs, suitable for the greenhouse.

Leaves alternate, entire or crenate-serrate; stipules minute, subulate, caducous: fls. yellow, in axillary and terminal cymose fascicles, rarely solitary; sepals 5, entire, lanceolate, acuminate; petals 5, contorted, fugacious, much longer than the sepals; stamens 5; ovary 3-5-celled: caps. globose, splitting into 6-8 cocci. —Two species, India. The genus is closely allied to the flax (*Linum*), and *Reinwardtia trigyna* is known to this day as *Linum trigynum* by the gardeners, who usually accent trigynum on the second syllable instead of the first. *Reinwardtia* is distinguished from *Linum* by the yellow fls., 3-4 styles and unequal or deficient glands; *Linum* has mostly blue, rosy or white fls., 5 styles, and equal glands.

Reinwardtias are showy subshrubs about a foot high with bright yellow flowers. They are useful for the decoration of the conservatory in winter time, at a season when yellow is scarce. To have presentable plants, it is necessary to give them a good deal of attention. It is difficult sometimes to get suitable cuttings; the strong growths which start away from the base when the plants are cut down make the best plants. Topshoots will grow, but seldom make good plants, as they are liable to go to bloom prematurely. Sandy loam is the best compost. Plants that have been grown in pots for

3360. *Reinwardtia trigyna*. (× 1/4)

a season may be planted out in early summer, and these will make good plants and furnish cuttings. They will have to be topped frequently and carefully lifted. Young stock is better kept in pots, as the plants do not lift well. Sunshine is essential during the winter season to get the best development of reinwardtias. They thrive best in a temperature of 55–60°. (T. D. Hatfield.)

A. *Lvs. entire: styles 3.*

trigyna, Planch. (*R. indica*, Dum. *Linum trigynum*, Roxbg.). Fig. 3360. Lvs. elliptic-obovate, entire or minutely toothed, tip rounded or subacute. B. M. 1100. Gn. 29, p. 279. G. 6:611; 10:344; 32:101. G.W. 2, p. 297. H.F. II. 6:136. J.H. III. 54:507.—Grows 2–3 ft. high in the wild.

AA. *Lvs. toothed: styles 4 or 3.*

teträgyna, Planch. Lvs. elliptic-lanceolate, acuminate, crenate-serrate. B. M. 7136. G.C. III. 16:721. R.H. 1867:292. Gn. 61, p. 198. WILHELM MILLER.

F. TRACY HUBBARD.†

REMUSÄTIA (named for G. P. A. Remusat, 1785–1832). *Araceæ*. Tuberous herbs, flowering and leafing in alternate years, and bearing long radical bulbiferous shoots; warmhouse foliage plants. Lf. solitary, entire, peltate: spathe coriaceous, tube convolute, ovoid, limb broad or narrow, deciduous; spadix very short, sessile, male and female infl. separated by neuters, appendage none; male infl. clavate, female short and cylindric; ovaries ovoid, 1-celled: berries small.—Three or 4 species, natives of the mountains of India and Java.

vivipara, Schott. Tuber the size of a hazel or walnut; bulbiferous shoots very stout, suberect or ascending, simple or very shortly branched: lf. 5 x 3½–18 x 12 in., membranous, orbicular, ovate or cordate, acute or acuminate; petiole 1 ft. or less long; spathe 4–5 in. long, tube green, limb broadly orbicular-obovate, cuspidate, 2–3 in. broad, golden yellow; spadix 1–1½ in. long. India and Java.

RENANTHERA (named from the reniform anther). *Orchidaceæ*. Tall climbing epiphytes.

Stems branched, sometimes 12–14 ft. high: lvs. distichous on the st.: fls. in large, drooping racemes or panicles; sepals and petals spreading, similar or the lateral sepals often larger and of a different color; labellum small, movably joined to the column, spurred or spurless, often with small, erect, lateral lobes.—About 15 or more species, in Malay Archipelago and Cochin-China. Cult. is similar to that of *Aërides* and *Vanda*.

coccinea, Lour. Fig. 3361. Sts. 8–10 ft. high, branched, climbing by means of white fleshy roots: lvs. in 2 rows, oblong, notched at the end, 4–5 in. long; fls. open, 2–3 in. across, in loose, branching racemes 2–3 ft. long, very brilliant; petals and dorsal sepal linear-spatulate, deep red, blotched with orange; lateral sepals larger, oblong, broader toward the apex, undulate, deep crimson, with palertrans verse lines; labellum small. Autumn. Cochin-China. B. M. 2997, 2998. B.R. 1131. P.M. 4:49. F.S. 7, p. 163. G.C. 1845:491.—Does not flower readily in cult., but is very showy.

Störici, Reichb. f. St. slender, climbing, 10–12 ft. high: lvs. alternate, oblong to linear-oblong; panicle about 1 ft. long and nearly as broad; fls. 2½–3 in. long; petals and dorsal sepal erect, linear-spatulate, orange-red, mottled with crimson; lateral sepals pendulous, obovate-spatulate, undulate, crimson with large blood-red blotches; labellum very small. Philippines. B. M. 7537. Gn. 53, p. 119. G.M. 39:659.

Lôwei, Reichb. f. (*Vanda Lôwei*, Lindl.). Fig. 3362. Sts. very long, climbing, somewhat branched: lvs. rather crowded, strap-shaped, 2–3 ft. long: racemes

from the upper axils, 6–12 ft. long, bearing 40–50 fls.; fls. of two kinds, the lowest pair tawny yellow with crimson spots, the others larger, pale yellowish green, irregularly blotched with reddish brown; sepals and petals lanceolate, acute, undulate, on the lowest pair shorter, blunter, and more fleshy. Borneo. B. M. 5475. I.H. 11:417. R.H. 1868:110; 1884, p. 343. F.S. 21:2256. Gt. 37, pp. 108, 109. Gn. 11, p. 524; 16, pp. 354, 355; 32, p. 197. G.C. II. 20:657; III. 27:3.—A very remarkable orchid.

R. annamensis, Rolfe. Dwarf, erect, up to 1 ft. tall: lvs. unequally 2-lobed at apex, 2–3 in. long, about ½ in. broad: racemes

many-fld.; fls. yellow, crimson-spotted on the sepals, spur and base of petals, the last also with an apical deep crimson spot; dorsal sepal oblong, obtuse, ½ in. long, the lateral spatulate, ¾ in. long; petals obtuse, ¼ in. long; lip 3-lobed, ¼ in. long, the lobes crimson. Annam. B. M. 8116.—*R. Imschootiana*, Rolfe. Sts. 1 ft. long: lvs. linear-oblong, 2–4 in. long, 1 in. wide: infl. a raceme or panicle, up to 1 ft. long, the rachis, branches and pedicels bright red; dorsal sepal linear-oblong, obtuse, dull yellow, ¾ in. long, lateral 1½ in. long, clawed, oval, cinnamon-red above, ochre beneath; petals a little shorter than dorsal sepal, narrowly spatulate, yellow, spotted blood-red; lip minute, 3-lobed. Assam. B. M. 7711. Gn.W. 11:809. O. 1910, p. 24.—*R. matulina*, Lindl. St. 2–3 ft.: lvs. linear-oblong, 4–6 in. long: fls. numerous, reddish crimson, toned yellow, and becoming orange-yellow when old; sepals and petals similar, linear, acute; lip saccate, subcylindric. Java. R.B. 31:252.—*R. pulchella*, Rolfe. Resembling *R. Imschootiana*, but fls. only about half the size, yellow, with side lobes of lip and upper half of petals crimson. Burma.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

RENEÁLMIA (in honor of Paul Reneaulme, a French botanist). *Zingiberaceæ*. Perennial aromatic herbs, suitable for cult. in the warmhouse or outdoors in the extreme S.: rootstock fleshy: sts. leafy: lvs. more or less long-petioled or sessile, lanceolate or oblong: infl.

terminal or scapose and either paniculate or racemose; fls. white, yellow or red; calyx short, 3-lobed; corolla short-tubed, the lobes erect or finally spreading, subequal or the posterior broader and concave; ovary 3-celled: caps. globose. About 60 species, Trop. Amer. and a few in Trop. Afr. *R. exaltata*, Linn. f., is recently intro. as a dye-plant; also ornamental, with reddish peduncles and bracts, and yellow fls.: lvs. like a canna: the fleshy hulls of fr. yield dye and ink. W. Indies.

3362. *Renanthera* Loweii.
($\times \frac{1}{2}$)

RESÈDA (from the Latin *to calm*; said to allude to supposed sedative properties). *Resedaceæ*. One species is grown as a garden annual, and also under glass, for its pleasing fragrance: *Mignonette*, which see (Vol. IV, p. 2049).

Herbs (sometimes partially woody at the base) with alternate, simple or compound lvs., and terminal spikes of inconspicuous perfect fls., which have 4-7 small greenish toothed or cleft unequal petals and 8-40 small stamens attached on one side of the fl.: pistil 1, ripening into a 3-6-horned or -angled cap. that opens at the top at maturity (Fig. 3363), and contains several to many seeds. Only one species, the common *mignonette* (*R. odorata*), is generally known, but two or three other species are sometimes grown. Two other species are occasional weeds in the East.—*R. Luteola*, Linn., the dyer's weed (formerly used as yellow dye), 1-2 ft. tall, with entire lvs., 4 or 5 greenish petals of which the lowest one is entire; and *R. lutea*, Linn., with pinnatifid lvs. and petals usually 6; and two or three of the perennial species are more or less recommended as border plants. This genus contains 50-60 species, most of which are native to the Medit. basin, Arabia and Persia.

A. Lvs. entire or only notched.

odorata, Linn. COMMON MIGNONETTE. Fig. 3363; also 2372, p. 2049. Branching annual herb, at first upright but becoming wide-spreading and more or less decumbent: lvs. spatulate or oblanceolate, mostly obtuse, usually entire but sometimes notched: fls. yellowish white, in spicate racemes that become loose and open with age, very fragrant. N. Afr. B.M. 29. Gn. 55, p. 409.—Much grown for its strong and agreeable fragrance: It has been greatly modified under domestication. The following garden names seem to belong to this species: *arboorea*, *ameliorata*, *compacta*, *eximia*, *gigantea*, *grandiflora*, *pyramidalis*, *multiflora*,

pumila; they represent stature-forms and habit-forms of the horticulturists. Var. *suffruticosa*, Edw., is woody at the base. B.R. 227. Many named varieties of *R. odorata* are in the trade. See *Mignonette*.

glauca, Linn. Glabrous and somewhat glaucous perennial, less than 1 ft. tall, with many spreading sts.: lvs. narrow-linear, entire, or 2-toothed near the base: petals 5 or 6, the upper ones 3-lobed; stamens about 14. Pyrenees.—Recommended for dry places, as a border plant. See p. 1467.

AA. Lvs. usually prominently lobed or pinnatifid.

alba, Linn. WHITE UPRIGHT MIGNONETTE. Straight-growing erect glabrous annual or biennial, 1-3 ft., weedy: lvs. numerous, long-stalked, deeply and irregularly pinnatifid, the segms. usually linear and sometimes toothed: fls. greenish white, in a very long slender spike; stamens about a dozen, and petals 5-6. S. Eu. G.C. III. 20:45. G.W. 8, p. 255.—A commendable plant for growing as an ornamental subject in the fl.-border with other plants. It bears many spikes on tall branches, making it a conspicuous plant; treated as a half-hardy annual; odor not pleasing. It occurs somewhat in this country as an adventive plant.

crystallina, Webb. Glabrous, sparingly branched, somewhat glaucous annual: lvs. usually 3-parted, or the lowest ones entire: fls. deep yellow, in racemes. Canary Isls.—Has been offered as a garden annual.

L. H. B.

RÉSTIO (Latin, *rope*, alluding to the use made of the plants in S. Afr.). *Restiaceæ*. Perennial herbs with a tufted or creeping rootstock, of little horticultural significance: sts. terete, compressed or 4-sided, with remote sheathing lf.-sheaths, usually more or less mucronate, sometimes prolonged into a linear blunt lf.: male and female infl. similar or dissimilar, spicate, spikes solitary or spikelets numerous in spicate or paniced cymes; fls. dioecious, 1-bracteate; perianth usually of 6, sometimes 4 segms. in 2 rows, rarely none; ovary 2- or 3-celled: caps. 2- or 3-celled, or by abortion 1-celled, 1 seed in each cell. About 170 species, half of them from S. W. Afr. the remainder from S. W. Austral. *R. subverticillatus*, Mast. Sts. erect, 3-4 ft. high, with verticillate branches: sheaths about 1 in. long, coriaceous, striate above, membranous, spreading, acuminate, smaller sheaths foliaceous from beneath a 2-lobed hyaline apex: perianth-segms., male, broadly oblong, the lateral villous-keeled, female broader: caps. obliquely ovate, 1-celled, 1-seeded. S. Afr. G.M. 43:76.

REST-PERIOD IN PLANTS. The rest-period of plants is that period or stage when the part or parts at inaction are incapable of responding to favorable growing conditions. A rest-period of some length, either short or long, appears to be universal with all perennial plant forms. So far as known, none has a continuous growth. Trees and shrubs growing in the open, both in cold and warm climates of the temperate zone, may begin to enter the rest-period in some of their branches as early as midsummer. This is indicated by cessation of length growth and formation of terminal buds. Some may be ready to grow again in a few weeks, while others are unable to grow for five or six months. Herbaceous perennials begin their rest after dying down in summer or fall. The death of the aerial parts is accompanied by the formation of strong crown-buds. They are usually ready to resume growth within a few days or weeks, although there are notable

3363. Pod of *Reseda* *odorata*. ($\times 2$)

exceptions. Bulbs begin their rest when the tops die down after flowering. Many will not grow again for several months. Many seeds germinate poorly, or not at all, if planted immediately or shortly after ripening. Failure to grow is usually due to the influence of a rest-period. However, aside from the effects of a rest-period, seeds may fail to germinate promptly or at all on account of a hard or tough seed-coat which is more or less impervious to water. In garden practice, seeds are stored for a few weeks or months before planting in order that they may pass through a period of "after-ripening." Those with hard or tough seed-coats are stored by stratifying in moist sand.

Investigation has shown that practically all woody plants native to the temperate zone have a rest-period. Many of these are unable to grow in late fall or early winter, even when transferred to a warm moist greenhouse. In trees and shrubs the rest-period begins to set in as early as midsummer. The length of the rest varies greatly. In some cases it may last only a few days or weeks, while in others it may persist from three to six months. Red raspberries, mountain-ash, and spruces are almost free from a rest-period, while white oak, tulip tree, and American beech commonly rest for six or seven months. Among herbaceous perennials, the lily-of-the-valley is conspicuous for its rather long rest-period which usually lasts for two or three months. Asparagus, rhubarb, hardy chrysanthemum, golden marguerite, calliopsis, and a host of others are ready to grow again in a week or two after the old plants die down. All spring-flowering bulbs appear to have a distinct rest-period lasting from three to five months. From 50 to 75 per cent of the seeds of herbaceous plants, annual and perennial, have a rest-period, while the resting phase is noticeable and generally very distinct in fully 90 per cent of the seeds of trees and shrubs.

The rest-period is commonly looked upon as the period of dormancy in plants and seeds, but this view is incorrect. The rest-period of trees, for example, begins and ends entirely independent of the winter season. While cold weather may prevent growth from taking place, it does not necessarily prevent the rest-period from coming to an end and thus leaving the trees ready to grow as soon as surrounding conditions are favorable. In mild climates the rest begins and ends with great regularity. The same is true in cold climates, but in the case of trees, at least, the true condition of affairs is not apparent on account of the interference of the cold which prevents growth. In trees the rest sets in gradually twig by twig and is not complete until all the growing points have ceased elongating and formed terminal buds. In like manner the trees pass out of their resting state gradually, some twigs often being ready to grow much earlier than others. These phenomena are very noticeable when trees are grown under glass.

The rest-period of many trees and shrubs may be broken or greatly shortened by special treatments. Those with a long rest-period are very difficult to arouse during the early stages of their rest. The greater part can be forced with comparative ease during the middle period of their rest and to some extent during the latter phases, although at this time the treatments must be less severe or the plants may be killed. The agents most generally used for forcing growth are ether, drying, and freezing. Submerging in warm water will sometimes start growth, particularly in dormant twigs. Twigs of flowering shrubs, such as lilac, deutzia, spirea, and golden-bell, may be caused to burst into bloom in early or midwinter by placing them in a tight vessel and pouring in ether at the rate of one teaspoonful to each two gallons of space. Allow the plants to remain in the ether vapor for twenty-four hours, when they should be taken out and stood in vessels of water in a warm moist room. It is very necessary to have the air

moist to keep the buds from drying out before they begin to grow. Potted plants of all kinds, both woody and herbaceous, may be similarly treated, provided the surface of the soil in the pots is dry, as moist or wet soil will absorb too much of the ether. Many herbaceous plants do not respond to the ether treatment and some are killed. The best treatment for forcing hardy herbaceous perennials is to lift them in the fall, subject them to a temperature a few degrees below freezing for twelve to twenty-four hours, and then place them in a mild hotbed. By mid- or late winter most plants may be forced with heat alone. There are perhaps thirty or forty different agents that have been successfully used for forcing plants.

Of just what value the rest-period is to the different plants and plant parts is not known. It is highly probable, however, that the period of inactivity is utilized for the conservation of energy through the special work the enzymes are able to perform while the growing parts are dormant, that they could not do in the presence of active growth.

The cause of the rest-period and the specific effects of the rest-period-breaking agents on the plant organism have been carefully studied only in connection with woody plants. It has been thought that the rest-period in trees sets in on account of the inhibition of enzyme activity due to an over-accumulation of the products of their work. The early phases of the rest-period occur and are passed through while the plants are in full leaf and often while some of the parts are still making active growth. The parts to enter the resting state first, in fruit-trees particularly, are the so-called spurs which are short lateral outgrowths usually arising from wood that grew the previous year. These cease growing early in the season, probably because of imperfect sap circulation. The crude sap from the roots rises most rapidly in those branches and twigs that are nearest in a straight line upward from the ground. It would appear then that the spurs, on account of their position, are deprived of water very early in the growing season. Assimilation goes forward rapidly in those parts that first approach a state of maturity. With a decreased water-supply and a greatly increased deposition or accumulation of carbohydrates, enzyme activity is soon checked if not entirely inhibited. As the season advances, the approach of cool weather may hasten the period of dormancy, but the trees would go dormant just the same, although later, in a mild climate or under glass. It is thus seen that the rest-period of trees is gradual, beginning in the spurs and gradually involving all of the branches.

Briefly, the rest-period perhaps begins to set in on account of the inhibition of the enzymes by the over-accumulation of the products of their work. This is the early rest of mid- or late summer. In the fall, excess supplies of carbohydrates continue to be accumulated and, with trees growing in the open, the further inhibition of the enzymes is actively aided by the approach of cool weather. These factors acting together bring about the main or middle state of rest. However, since dormant trees are never completely at rest, respiration continuing all the time, and doubtless enzyme activity too, the over-accumulation of carbohydrates is gradually reduced. Toward the last of this period occurs the after-rest, which, as the enzymes become more and more active, gives place to the beginning of growth.

Research has shown that diastatic, proteolytic, fat-splitting, and oxidizing enzymes all play a prominent part in bringing about, as well as ending, the rest-period in woody plants. Any forces or agents that will reduce the activity of these ferments will be the means of causing the rest-period to set in and, similarly, any agent that will stimulate the enzymes into activity will be the means of bringing the rest-period to an end. (See Research Bulletins Nos. 1, 15, 16, 17, 21, Missouri Agricultural Experiment Station.) W. L. HOWARD.

RESTREPIA (Joseph Emanuel Restrep, a student of natural history in the tropics). *Orchidaceae*. Very interesting little plants, allied to *Masdevallia* and not unlike that genus in habit and appearance.

Stems tufted on creeping rhizomes, each bearing a single lf. and clothed below with scales; fl.-sts. appear from the axil of the lvs.: perennial, producing fls. for several years in succession: dorsal sepal free, ending in a filiform, clavate tail; lateral sepals united into a broad blade, bifid only at the apex; petals like the dorsal sepal, but smaller; labellum oblong or ovate, often with 2 small teeth near the base.—About 40 species, from Brazil to Mex., few of which are cult. for their curious fls. They are easily grown at a temperature suited for cool odontoglossums (40–55°). They thrive well planted in a mixture of peat and sphagnum in baskets, which are usually suspended near the glass. They have no definite resting period, but do not require so large a quantity of water in winter as during their most active growth. Pot moderately firm, and rest in a coolhouse.

antennifera, HBK. Sts. slender, clustered, 4–6 in. high, clothed with imbricated scales, and bearing one (rarely more) ovate-cordate petioled lf.: peduncle from the axil of the lf., slender, 1-flid.: dorsal sepal 1½ in. long, lanceolate, tapering into a slender clavate tail, yellow, with purple lines and a purple tip; lateral sepals united into an oblong blade 2-lobed at the tip, yellow, marked with red-purple dots; petals small, antenna-like, purple at the tip. Nov.–Feb. Colombia, Venezuela. B.M. 6288; 7930. I.H. 16:601. A.F. 6:631.

Dayana, Reichb. f. A small plant growing in dense tufts: lvs. roundish, acute, cordate; dorsal sepal and petals filiform, clavate, shining, violet-brown; lower sepals united into a broad, bifid blade, yellow and brown. Costa Rica.

élégans, Karst. Tufted, epiphytic, 2–3 in. high: lvs. 1–1½ in. long, elliptic; peduncles usually in pairs: fls. 1½–2 in. long; dorsal sepal erect, lanceolate, white, streaked purple, with a tail as long as itself, which is clubbed at the tip and yellow; lateral sepals connate into an oblong, emarginate, concave blade, yellow, spotted purple; petals like the dorsal sepal, but spreading and only half the size; lip half the size of the connate lateral sepals and of the same color but edged with red. Venezuela. B.M. 5966. F.S. 7:743.

R. aspascensium, Reichb. f. Only 2–3 in. high: fls. small, deep yellow, densely spotted with crimson or chocolate-brown. Venezuela.

HEINRICH HASSELBRING.

RESURRECTION PLANTS are such plants as “come to life” after being apparently dead. They are kept in a dried state as curiosities, to be “resurrected” on occasion, and sometimes they are grown for a similar purpose but they are scarcely horticultural subjects.

3364. Rose of Jericho in the dry state.

The commonest resurrection plants are members of the mustard family and the club moss family. Others are *Asteriscus*, a composite, and *Mesembryanthemum*, of the fig-marigold family. Many plants can be similarly revived from the dried state, particularly those of desert regions.

1. The rose of Jericho is properly *Anastatica hierochuntica*, Linn., which name means “resurrection plant from Jericho.” The plant is

the tips or on the sides of the inrolled branches. (Fig. 3365.) The plants are up-rooted by the winds and are blown about on the deserts. These balls were thought by many to be “the rolling thing before the whirlwind” mentioned in Isaiah, and were brought to Europe by the crusaders. The shape of these balls

3365. Rose of Jericho as it opens after being moistened.

might be fancifully compared to that of an unopened rose. When the winter rains descend or when the balls are blown into the Mediterranean the branches at once open back and stretch out straight, the fruits open, and

the seeds germinate very quickly, “often in the fruit,” according to Warming. The dead plants do not, of course, “come to life,” but they retain their hygroscopic properties for many years.

Botanically, *Anastatica* is distinct by reason of its short and broad fruit or silicle, which has two ear-like appendages at the top. The silicle is divided by a transverse partition into two cells, each of which contains a seed. There is only one species. The genus belongs to the *Arabis* tribe of the *Cruciferae*, but is exceptional in not having a long slender silicle. The growing plant has obovate leaves, the lower ones entire, upper ones toothed, and the flowers are small, white, and borne in spikes in midsummer. Excellent pictures of resurrection plants may be found in Kerner & Oliver’s “Natural History of Plants,” together with accounts of the behavior of the various kinds. See also B.M. 4400, G.C. 1872:1068, Gn. 4, p. 111. These plants have much folk-lore.

2. The bird’s-nest moss, *Selaginella lepidophylla*, is a native of Mexico and reaches into western Texas. Many *Selaginellas* curl up if allowed to dry, and several of the Mexican species do so in their native places in the dry season, but this species is said to make a tighter mass than any other. When placed in lukewarm water the fronds loosen and roll back into a flat or saucer-like position. The plant may become green and grow, and it is also said that it may be dried and revived an indefinite number of times. The specimen shown in Figs. 3366, 3367 was “resurrected” four times after it came into the hands of the Editor, and showed no indications of a limit to its reviving possibilities. *Selaginellas* are beautiful moss-like plants. What appear to be the leaves are really the branches, and the true leaves are scale-like. See Gn. 17, p. 400; F. 1871, p. 144; also *Selaginella*.

3. A member of the composite family (*Odontospermum pygmaeum*, or *Asteriscus pygmaeus*) is also called rose of Jericho, has the same range as No. 1, and was also brought to Europe by the crusaders. (Fig. 3368.) The branches do not roll up, but the involucre closes over the head of fruit in the dry season, and is loosened by moisture when the seeds escape.

3366. *Selaginella lepidophylla*, one of the resurrection plants. (×½)

4. Several species of *Mesembryanthemum* are known to be hygroscopic. According to Kerner & Oliver, "the capsular fruits of these plants remain closed in dry weather; but the moment they are moistened the valves covering the ventral sutures of the fruit-loculi open back, dehiscence takes place along the ventral

3367. The plant shown in Fig. 3366 when "resurrected."

sutures, and the seeds, hitherto retained in a double shroud, are washed out of the loculi by the rain." It is doubtful whether these capsules are offered in the trade.

WILHELM MILLER.

The cultivation of resurrection plants.

Anastatica is sometimes grown for curiosity or for botanical purposes, but the plant is anything but ornamental. It has often been grown for classes in botany, sowing the seed in February in pots and keeping the plants in pots all summer. Bottom heat is not necessary at any stage, at least in America. The plant could be grown in a window-garden. The seeds may be sown in February in 4-inch pots, using a light, sandy soil, in a house with a temperature of 60° F. As soon as the seedlings are large enough they are transplanted into other 4-inch pots, three plants to a pot.

The *Selaginella lepidophylla* is perennial. It is rarely cultivated in greenhouses for ornament, like the evergreen kinds of selaginella. It is grown chiefly in botanic gardens or by fanciers of ferns and selaginellas, as it is by no means the most beautiful member of the genus. The writer grew a plant of it for four years, and once saw at one of the botanical gardens a plant which through long cultivation had developed a stem almost a foot high. It looked like a miniature tree-fern, except of course that the fronds were arranged in a dense rosette, which gave the fronds a flat rather than a pendulous appearance. Whether the plants received directly from Texas have a crop of spores on them is a question. The spores do not discharge when the plants are wetted. Many extravagant statements are made about the bird's-nest moss. The dried plants offered by the trade will turn green and grow unless they are too old or have been kept dry too long. They would probably not grow if kept over more than one season. They cannot be dried again and again indefinitely and still remain alive.

3368. Another "rose of Jericho," *Odontospermum*, or *Asteriscus*. The bracts roll out and make a flat star-shaped figure.

If a plant has been grown in a pot three or four years and is then dried off it will die. Most persons who grow these plants as curiosities place them in a bowl of water with perhaps a little sand and a few pebbles. The water causes them to turn green and they will grow for a time. Then if taken out of the water they may be kept dry for a time and the process repeated, but each time the plant loses its lower or outer circles of fronds much faster than new ones are made and at about the third time the plant is commonly used up.

There is a fern (*Polypodium polypodioides*, page 2744) which could just as truly be called a resurrection plant. It is a native of the southern states, where it grows up the trunks of trees and over rocks and stones. At certain times it is dried up and parched, but as soon as moisture conditions are restored it looks as fresh as ever. In warm dry countries there are ferns of various genera that dry up and then are resurrected quickly when wet weather comes; some of these are very interesting.

EDWARD J. CANNING.

RETARDING is the opposite of forcing, and consists in keeping plants in cold storage, thereby preventing them from growing during their natural season. Its object is to supplement natural methods and forcing in order to produce the same thing the year round. The lily-of-the-valley is one of the plants of the first importance which may be retarded in commercial establishments. There is sufficient demand for these flowers all the year round to justify the expense of cold storage. Lily-of-the-valley "pips" may be taken from cold storage and forced into bloom in three weeks. Plants that have been retarded need very little heat when they are allowed to grow; they are eager to start, and a temperature of 45° to 50° is sufficient. *Lilium speciosum*, *L. longiflorum*, and *L. auratum* will bloom in ten to twelve weeks from cold storage; *Azalea mollis* in three to four weeks; spireas in about five weeks. Sea-kale and lilacs have also been retarded with profit. Goldenrod has been kept in an icehouse all summer and flowered for Christmas with good results. The art of retarding plants is making progress at present, and with the growth of popular taste for flowers the list of retarded plants may be greatly extended in the future. See A. F. 16:654, 655 (1900).

RETINISPORA. Often but not originally spelled *Retinospora*. A genus of conifers founded originally by Siebold and Zuccarini on the two Japanese species of *Chamaecyparis*, chiefly distinguished from the American species by the resinous canals of the seeds (from Greek, *retine*, resin, and *spora*, seed). Afterward the genus was united with *Chamaecyparis*, but in horticultural nomenclature the name is applied to a number of juvenile forms of *Thuja* and *Chamaecyparis*, chiefly those introduced from Japan. As these juvenile forms all resemble each other very much, indeed much more than do the typical forms to which they belong, it is not strange that they should have been considered to be distinct species and even to belong to a separate genus. Even botanists failed to recognize the true relation of these forms and went so far as to place one of them in the genus *Juniperus*. With the exception of *Retinispora ericoides*, which C. Koch recognized as the juvenile form of *Thuja occidentalis*, the origin of these juvenile forms remained doubtful until L. Beissner, after having carefully studied the subject for years, disclosed the relationship of the various forms. He showed by experiment that it is possible to raise the same form by making cuttings from seedlings which have still retained their primordial foliage, and he also published cases in which larger plants of these doubtful forms have been observed accidentally to develop branches with the foliage of the typical form. See, also, Gt. 1879, pp. 109 and 172; 1881, pp. 210 and 299, and 1882, p. 152.

There are four of these juvenile forms generally in

cultivation, each of them with an intermediate form showing either a kind of foliage approaching that of the type or two different kinds of foliage on the same plant. There seems to be no doubt that all these forms have been secured by propagating branches of young seedling plants. All seedlings of *Chamaecyparis*, *Thuja*, and other genera of the Cupressineae produce in their juvenile state a kind of primordial foliage very different in appearance from that of the adult plants. The first leaves are always linear and spreading, passing gradually into acicular and at last scale-like leaves. In some plants, especially if they have not sufficient nourishment, the primordial foliage is retained longer than usual and these have probably been selected for perpetuating the juvenile state, by means of cuttings. By continuing through many generations the propagation of those branches which show the juvenile state most distinctly, these forms have become well-fixed varieties and even sometimes bear seeds without changing the foliage on the fruiting branches. These seeds, however, produce plants of the typical form and only a few of them retain the primordial foliage somewhat longer than usual.

The juvenile forms very much resemble some species of *Juniperus* in habit and foliage. They bear linear spreading leaves in pairs, changing in winter to a

3369. *Retinisporas*. The specimen on the left is *Thuya orientalis* var. *decussata*; middle, *Chamaecyparis thyoides* var. *ericoides*; right, *C. thyoides* var. *andelyensis*. ($\times \frac{1}{2}$)

brown, reddish, violet or steel color, and do not show the regular frond-like branching of the typical forms. The leaves, however, are much softer and not sharply and acutely pointed as in *Juniperus*; they are mostly marked with whitish or grayish green lines beneath, which is never the case in *Juniperus*. Only *Thuya orientalis* var. *decussata* and some intermediate forms, with acicular suberect leaves, show whitish marks on the upper side of the leaves like *Juniperus*.

Though these *Retinispora* forms are described under the genera and species to which they belong, where also references to illustrations are cited, descriptions are given here to afford a closer comparison of these similar and much confounded forms. The two forms of foliage in the common red cedar are well shown in Fig. 2025, Vol. III. For other pictures of *Retinispora* forms see *Chamaecyparis* and *Thuja*.

Chamaecyparis obtusa var. *ericoides*, Boehmer (*Retinispora Sanderi*, Sander. *Juniperus Sanderi*, Hort.). Dense round-headed bush with upright branches and bluish gray foliage: lvs. acicular, decussate, spreading, about $\frac{1}{2}$ in. long, thickish, concave above and with a green line in the middle, the lower lvs. often acutish, the upper ones obtuse.

Chamaecyparis pisifera var. *squarrosa*, Beissn. & Hochst. (*Retinispora squarrosa*, Sieb. & Zucc.). Fig. 893. A dense, pyramidal or round-headed bush or some-

times small tree, with light bluish green foliage almost silvery white when young, usually coloring violet in winter: tips of branchlets nodding: lvs. crowded, spreading, very soft, bluish green above, silvery white below. The most ornamental and graceful and the best known of these juvenile forms. The intermediate form, var. *plumosa*, Beissn. & Hochst. (*Retinispora plumosa*), has smaller, subulate and suberect lvs., and is much planted, especially in its golden variegated form. See Fig. 892, Vol. II.

Chamaecyparis thyoides var. *ericoides*, Sudw. (*Retinispora ericoides*, Zucc.). Fig. 3369. Dense shrub, of stiff, pyramidal or almost columnar habit, with upright branches and bright green foliage, changing to violet-red or brownish red in winter: lvs. bright green above, with 2 bluish lines below. This form is very distinct with its stiff, columnar habit, but is less common in cult. The intermediate form, var. *andelyensis*, Schneid. (*Retinispora leptoclada*, Hort.), shows also a stiff, pyramidal habit and bears chiefly small, suberect or almost scale-like lvs., and occasionally branchlets with spreading linear lvs. Fig. 3369.

Thuja occidentalis var. *ericoides*, Beissn. & Hochst. (*Retinispora ericoides*, Hort. *R. dubia*, Carr.). Dense broadly pyramidal or round-headed bush, with upright branches and dull green foliage, changing to brownish green in winter: lvs. linear, soft grayish green beneath. The intermediate form, var. *Ellwangeriana*, Beissn. (*Retinispora Ellwangeriana*, Hort.), has usually two kinds of lvs., but the linear lvs. are smaller than those of the preceding form.

Thuja orientalis var. *decussata*, Beissn. & Hochst. (*Retinispora juniperoides*, Carr. *R. decussata*, Hort. *R. squarrosa*, Hort.). Fig. 3369. Dense, round-headed bush, with bluish green foliage changing to violet or steel-color in winter: lvs. rather rigid, bluish green, spreading, concave and with a whitish line above. But rarely cult. and not quite hardy N. The intermediate form, var. *meldensis*, Laws. (*Retinispora meldensis*, Hort.), has mostly acicular suberect lvs. of the same color as in the preceding var. *andelyensis*.

These juvenile forms are valuable for formal gardening, for rockeries, small gardens and wherever slow-growing and dwarf conifers are desired. They are short-lived and usually becomes unsightly when older. They are all readily prop. by cuttings. See also *Chamaecyparis* and *Thuja*.

ALFRED REHDER.

REYNOSIA (named for Dr. Alvaro Reynoso, 1830-1888, a Cuban agricultural chemist). *Rhamnaceæ*. Unarmed evergreen shrubs or trees, with rigid branches, sparingly cultivated, possibly for its edible fruit.

Leaves opposite, leathery, entire and emarginate; stipules small and caducous: fls. small, perfect, yellowish green, in sessile, axillary, umbel-like clusters; sepals 5, valvate spreading; petals wanting; stamens 5, inserted on the margin of the fleshy disk; ovary almost superior, 2-3-celled: drupe with a thin fleshy pulp and a crustaceous stone.—About 10 species, 1 in S. Fla.

latifolia, Griseb. RED IRONWOOD. DARLING PLUM. Slender tree, 20-25 ft. high: lvs. oval, oblong, or subrotund, usually emarginate, 1-1½ in. long, leathery; mar-

gins revolute; fls. in axillary umbels, borne in May; fr. ripens in Nov. or the following spring. S.S. 2:56.

F. TRACY HUBBARD.†

RHABDOTHÁMNUS (Greek, *rod and bush*, a shrub with many rod-like branches). *Gesneriáceæ*. Divaricately branched shrub, with slender branches: lvs. small, opposite, petioled, rotundate, coarsely dentate, often dissimilar: pedicels solitary in the axils, filiform and without bracts: fls. red-striped; calyx free, deeply 5-cleft, the lobes membranaceous, acuminate; corolla tubular-campanulate; the limb slightly oblique, somewhat 2-lipped, the lobes 5, rotundate, spreading and subequal; stamens 4, perfect; caps. ovate, acuminate, coriaceous, finally 4-valved.—One species, New Zeal. *R. Solándri*, A. Cunn. A much-branched, hispid shrub 1-3 ft. high; branches very slender, spreading at right angles: lvs. opposite, often in unequal pairs, oval or orbicular, coarsely toothed: fls. axillary, solitary, about 1 in. long; calyx hispid, 5-lobed, lobes lanceolate, acute; corolla glabrous, orange, striped red, limb 2-lipped, upper lip smaller, lower lip deeply 3-lobed, the lobes rounded: caps. ovoid acute. New Zeal. B.M. 8019. G.C. III. 37:146.

RHAMNÉLLA (referring to its close affinity to *Rhamnus*). *Rhamnáceæ*. About 6 species in E. Asia. Deciduous shrubs or small trees: lvs. alternate, stipulate, serrulate: fls. small, green, in axillary clusters; sepals, petals, and stamens 5; ovary incompletely 2-celled: fr. a black drupe with a 1-seeded stone. In habit resembling *Rhamnus*, but in fls. and frs. more like *Berchemia*. Only the following species is in cult.; it seems somewhat tender and has no particular ornamental qualities; cult. and prop. like *rhamnus*. *R. franguloides*, Weberbauer (*R. japonica*, Miq. *Micro-rhamnus franguloides*, Maxim.). Small tree, to 30 ft.: lvs. ovate-oblong, acuminate, finely serrulate, with 5-10 pairs of veins, glabrous except on the veins beneath, 2-5 in. long: fls. in 5-15-flid. clusters: fr. cylindric-oblong, black, $\frac{1}{3}$ in. long. Japan, Korea, E. China. S.I.F. 2:48.

ALFRED REHDER.

RHÁMNUS (its ancient Greek name). Including *Frangula*. *Rhamnáceæ*. BUCKTHORN. Ornamental woody plants grown chiefly for their handsome foliage and some also for their attractive fruit.

Deciduous or evergreen shrubs or small trees, sometimes spiny: lvs. alternate or opposite, short-petioled, with small deciduous stipules, penninerved, serrulate or entire: fls. small, in axillary clusters, umbels or racemes, perfect, polygamous or dioecious; sepals, petals and stamens 4-5, petals sometimes wanting; style usually undivided; ovary 2-4-loculed: fr. a globular or oblong 2-4-seeded drupe; nutlets with a leathery usually dehiscent wall.—About 100 species native chiefly to the temperate regions of the northern hemisphere. A few species are found in the tropics and as far south as Brazil and S. Afr. Several species yield yellow or green dyes and the frs. and bark of some are used medicinally. The wood of *R. Frangula* is made into charcoal valued for the manufacture of gunpowder.

The buckthorns are handsome shrubs with generally bright green often rather large leaves and with inconspicuous greenish flowers usually in axillary clusters followed by berry-like, usually black, rarely red, fruits. Many of the species as *R. cathartica*, *R. dahurica*, *R. fallax*, *R. Frangula*, and *R. alnifolia* can be depended upon as hardy, while *R. Purshiana* and *R. lanceolata* are hardy at least as far north as Massachusetts. *R. imeretina* and *R. caroliniana* are somewhat more tender. The handsomest in foliage are *R. fallax* and *R. imeretina* and the evergreen *R. ilicifolia* and *R. crocea*. *R. Purshiana*, *R. caroliniana*, *R. alnifolia*, *R. dahurica*, and *R. Frangula* are also noteworthy on account of pretty foliage. Of the evergreen species which are not

hardy North, *R. crocea* and *R. ilicifolia* are to be recommended for their ornamental bright red fruits. Buckthorns are useful for planting in shrubberies; they like a rather moist soil, especially *R. lanceolata*, *R. alnifolia*, *R. caroliniana*, and *R. Frangula*, and grow well in shaded or partly shaded situations, but *R. cathartica* and its allies prefer dry soil. *R. cathartica* is a valuable hedge plant, though it is now not used so extensively as in the past. The species are propagated by seeds stratified or sown in fall, and by layers. Some, as *R. lanceolata*, *R. fallax*, and *R. alnifolia*, are propagated by cuttings; *R. Purshiana*, has been successfully raised in England from softwood cuttings put in mild bottom heat under glass about the middle of July. The evergreen species are propagated by cuttings of ripened wood under glass. Rarer kinds are sometimes grafted, those of the *Frangula* group usually on *R. Frangula* and the true buckthorns on *R. cathartica* or allied species.

colchica, 5.	incana, 11.	

KEY TO THE SPECIES.

- A. Winter buds scaly: petals usually 4, sometimes 5 or wanting: seeds (not the outer coating of the nutlet) sulcate or concave on the back, with thin cotyledons recurved at the margins: fls. imperfectly dioecious. (*Eurhamnus*.)
 - B. Lvs. opposite: spiny shrubs.
 - C. Shape of lvs. ovate to oblong.
 - D. Length of lvs. $1\frac{1}{2}$ -3 in.; lvs. broadly ovate to elliptic, thin. 1. *cathartica*
 - DD. Length of lvs. $2\frac{1}{2}$ -4 in.; lvs. oblong-elliptic to oblong, leathery. 2. *dahurica*
 - CC. Shape of lvs. obovate, cuneate at the base. 3. *japonica*
 - BB. Lvs. alternate: unarmed shrubs.
 - C. Foliage deciduous.
 - D. Pairs of veins 12-25.
 - E. Branchlets and lvs. beneath glabrous. 4. *fallax*
 - EE. Branchlets and lvs. beneath pubescent. 5. *imeretina*
 - DD. Pairs of veins 4-9.
 - E. Fls. 6-merous, apetalous: lvs. oval. 6. *alnifolia*
 - EE. Fls. 4-merous, with petals: lvs. oblong-lanceolate. 7. *lanceolata*
 - CC. Foliage evergreen.
 - D. Veins 5-9 on each side: lvs. $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. apetalous.
 - E. Lvs. glandular denticulate: fls. 4-merous. 8. *crocea*
 - EE. Lvs. spinulose-dentate: fls. often 5-merous. 9. *ilicifolia*
 - DD. Veins 3-5 on each side: lvs. $\frac{3}{4}$ -2 in. long: fls. 5-merous, with petals. 10. *Alaternus*
 - AA. Winter buds naked: petals 5: seeds convex at the back, not grooved, with flat and fleshy cotyledons: unarmed shrubs with alternate lvs. (*Frangula*.)
 - B. Fls. in peduncled umbels.
 - C. Foliage evergreen. 11. *californica*
 - CC. Foliage deciduous.
 - D. Apex of lvs. obtuse or short-acuminate.
 - E. Peduncles usually longer than the petiole: lvs. with 6-15 pairs of veins, usually obtuse. 12. *Purshiana*

EE. Peduncles usually shorter than the petiole: lvs. with 5-10 pairs of veins, usually

DD. Apex of lvs. usually long-acuminate: lvs. pubescent beneath at least on the veins. 13. *caroliniana*

BB. Fls. in sessile umbels 15. *Frangula*

1. *cathartica*, Linn. BUCKTHORN. HART'S-THORN. WAYTHORN. RHINEBERRY. Fig. 3370. Shrub or small tree, attaining 12 ft., usually thorny: lvs. oval to elliptic or ovate, usually rounded at the base or cordate, obtuse

or acute, crenulate-serrate, beneath green, glabrous or pubescent, $1\frac{3}{4}$ -3 in. long: fls. in 2-5-fl. clusters, with 4 petals: fr. black, about $\frac{1}{4}$ in. across; seed with a furrow usually open only at the base. Eu., W. and N. Asia; often escaped from cult. and naturalized in the E. U. S. B.B. (ed. 2) 2:502. Gng. (ed. 2) H.W. 3, p. 56.

3370. *Rhamnus cathartica*. ($\times \frac{1}{2}$)

branches, sometimes a tree, to 30 ft.: branchlets glabrous: lvs. oblong or sometimes elliptic, narrowed at the base, acuminate, crenulate-serrate, glabrous, grayish green beneath, somewhat coriaceous at maturity, 2-4 in. long: fls. and fr. similar to those of the preceding species, but fr. somewhat larger. Dahuria to Amurland and N. China. G.F. 9:425 (as *R. crenata*; adapted in Fig. 3371).—Sometimes cult. under the name of *R. crenata*. Var. *nippōnica*, Makino. Lvs. narrow-oblong, light green beneath, 2-6 in. long and 1-2 in. broad. Japan. S.I.F. 2:48.

3. *japōnica*, Maxim. Spreading shrub with thorny branches, to 10 ft.: branchlets yellowish or grayish brown, lustrous: lvs. slender-stalked, obovate to oblong-ovate, short-acuminate, cuneate at the base, serrulate, sparingly pubescent or glabrous beneath, with 4-5 pairs of veins, 2-3 in. long: fls. in axillary clusters: fr. black, $\frac{1}{4}$ - $\frac{1}{2}$ in. across; seed usually with closed furrow. Japan. S.I.F. 2:48.

4. *fálax*, Boiss. (*R. alpina*, Auth., not Linn.). Shrub, to 10 ft., with stout, upright, glabrous and reddish brown branches: lvs. elliptic-oblong to oblong or obovate-oblong, cordate or rounded at the base, abruptly acuminate, crenulate-serrate, with 12-20 pairs of veins, dark green above, pale green and glabrous or nearly so beneath, 3-5 $\frac{1}{2}$ in. long: fls. in 3-7-fl. clusters; petals 4: fr. globose, black, $\frac{1}{4}$ in. across or less. Mountains of S. and Cent. Eu.—This and the following species are the handsomest of the deciduous-lyd. buckthorns because of the large size of their lvs.

5. *imeretina*, Koehne (*R. cólchica*, Somm. & Lev. *R. alpina* var. *cólchica*, Kusn. *R. alpina* var. *grandifolia*, Dipp. *R. libanótica*, Hook. f., not Boiss. *R. grandifolia*, Hort., not Fisch. & Mey. *R. castaneafolia*, Hort.). Allied to the preceding, but larger in every part: shrub, attaining 10 ft.: branchlets and petioles pubescent: lvs. larger and longer, to 8 in. long, pubescent beneath and often bronze-colored at maturity, with 15-25 pairs of veins. Caucasus, W. Asia. B.M. 6721. M.D.G. 1906:405.

6. *alnifolia*, L'Her. Low, wide-spreading shrub, attaining 4 ft., with puberulous branchlets: lvs. ovate to oval, obtuse or acuminate, usually narrowed at the base, crenately serrate, glabrous, $1\frac{1}{2}$ -4 in. long: fls. in few-fl. clusters, 5-merous, without petals: fr. globose, black, with 3 nutlets. New Bruns. and N. J. to Brit. Col. and Calif. B.B. (ed. 2) 2:503.

7. *lanceolata*, Pursh. Tall, upright shrub, with puberulous branchlets: lvs. ovate-lanceolate to oblong-lanceolate, acuminate or obtusish, finely serrulate, glabrous or somewhat pubescent beneath, 1-3 $\frac{1}{2}$ in. long: fls. in few-fl. clusters, with 4 petals: fr. with 2 nutlets. Pa. to Ala., Texas, and Neb. B.B. (ed. 2) 2:503.

8. *crócea*, Nutt. RED-BERRY. Evergreen shrub to 3 ft., with rigid often spinescent branches: lvs. orbicular to oblong-obovate, glandular-denticulate or serrulate, dark green and lustrous above, bronze- or copper-colored and glabrous or slightly pubescent beneath, $\frac{1}{8}$ - $\frac{3}{4}$ in. long: fls. in few-fl. clusters, 4-merous, apetalous: fr. bright red, about $\frac{1}{8}$ - $\frac{1}{4}$ in. across, edible. Calif.

9. *ilicifolia*, Kellogg (*R. crócea* var. *ilicifolia*, Greene). Evergreen shrub or small tree, to 12, or sometimes to 20 ft., with rather stout scarcely spinescent branches: lvs. oval to orbicular, spinulose-dentate, dark green and lustrous above, often golden beneath, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. often 5-merous, apetalous: fr. bright red, ovoid, $\frac{1}{4}$ in. long. Calif. S.S. 2:59 (as *R. crocea*).—This is superior to the preceding species on account of the more plentiful and somewhat larger bright red berries, also the lvs. are larger and resemble those of *Prunus ilicifolia*.

10. *Alaternus*, Linn. Evergreen shrub or small tree, attaining 20 ft., with glabrous branches: lvs. oval or ovate to ovate-lanceolate, acute, serrate or almost entire, glossy and dark green above, pale or yellowish green beneath, glabrous, $\frac{3}{4}$ -2 in. long: fls. in short racemes, with 5 petals: fr. bluish black. S. Eu. H.W. 3, p. 59. Var. *angustifolia*, DC. (*R. angustifolia*, Hort.), has narrower, oblong-lanceolate lvs. There are also varieties with variegated foliage.

11. *californica*, Esch. (*R. oleifolia*, Hook. *R. Purshiana* var. *californica*, Rehd.). COFFEE-BERRY. Evergreen shrub, to 15 ft.: lvs. oblong to oblong-lanceolate, acute or short-acuminate, serrulate or entire, glabrous and yellowish green beneath, 1-4 in. long: peduncles longer than petioles: fr. depressed-globose, changing from red to purplish black, about $\frac{1}{2}$ in. across. S. Ore. and Calif. to Ariz. and New Mex. R.H. 1874, p. 354. S.S. 2:63, fig. 3. Var. *tomentella*, Brew. & Wats. (*R. Purshiana* var. *tomentella*, Brandeg. *R. tomentella*, Benth. *R. incana*, Carr. *Frangula californica* var. *tomentella*, Gray). Allied to the preceding variety, but lvs. densely white-tomentose beneath. R.H. 1858, p. 658; 1872, p. 194. S.S. 2:63, fig. 2.

12. *Purshiana*, DC. CASCARA SAGRADA. Tall shrub to medium-sized tree, occasionally attaining 40 ft.: young branchlets pubescent or tomentose: lvs. elliptic to ovate-oblong, acute or obtuse, usually denticulate, with often wavy margin, dark green above, glabrous or pubescent beneath, 1-7 in. long: peduncles longer than petioles: fr. globose, changing from red to black, about $\frac{1}{2}$ in. across, with 2-3 nutlets. Brit. Col. to Mont., Idaho, and N. Calif. S.S. 2:62, 63.—Cascara Sagrada bark is extensively collected in Ore. and Wash. for use in drug manufacture.

13. *caroliniana*, Walt. INDIAN CHERRY. Shrub or small tree, attaining 30 ft.: young branches puberulous: lvs. elliptic to oblong, acute or acuminate, obscurely serrulate or almost entire, lustrous and dark green above, glabrous or nearly so, somewhat leathery at length, 2-6 in. long: peduncles shorter than petioles: fr. globose, about $\frac{1}{2}$ in. across, red changing to black, sweet, with 3 nutlets. N. Y. to Fla., west to Neb. and Texas. S.S. 2:61. B.B. (ed. 2) 2:503.

14. *crenata*, Sieb. & Zucc. Shrub, to 10 ft.: young branchlets and young lvs. rusty pubescent: lvs. oblong-ovate to oblong-lanceolate or obovate-oblong, acuminate or long-acuminate, finely crenate-serrulate, pubescent beneath, at least on the veins, with 7-12 pairs of veins, 2-4 in. long: peduncles usually shorter than petioles: fr. subglobose, $\frac{1}{2}$ in. across, changing from red to purplish black. Japan to Cent. China. S.I.F. 2:47.

15. *Frángula*, Linn. (*Frángula Álnus*, Mill.). Shrub or small tree, attaining 12 ft.: lvs. broadly obovate to obovate-oblong, acute, entire, dark green above, glabrous, 1-2½ in. long: fr. red, changing to black, with 2 nutlets. Eu., N. Afr., W. Asia and Siberia, escaped from cult. in some localities in the eastern states. Gng. 8:3. B.B. (ed. 2) 2:504. H.W. 3:48. Var. *asplenifolia*, Dipp. (*R. asplenifolia*, Simonkai, not Carr.). Lvs. linear, undulate; an interesting form of very distinct appearance with its feathery foliage. Var. *latifolia*, Dipp. (*R. latifolia*, Kirchn., not L'Her.). Lvs. to 5 in. long and to 2½ in. broad: fr. larger. Var. *heterophylla*, Mouillef. (var. *angustifolia*, Bean). Lvs. oblong to lanceolate, uneven, erose or irregularly lobed at the margin.—*R. Frangula* is a handsome shrub with shining foliage and attractive berries.

R. alpina, Linn. Closely allied to *R. fallax*. Young branchlets dull brownish gray, often pubescent: lvs. elliptic or oval, with 10-12 pairs of veins, 1½-3, rarely to 4 in. long: fr. smaller. Mountains of S. Eu. L.B.C. 11:1077.—*R. arguta*, Maxim. Unarmed glabrous shrub, allied to *R. cathartica*: lvs. opposite, orbicular-ovate, acuminate, sharply serrate, with bristly pointed teeth. Amurland. Probably hardy.—*R. Billardii*, Hort.=*R. hybrida* var.—*R. chlorophora*, Koehne (*R. chinensis*, Hort.). Shrub: branchlets glabrous or nearly so; lvs. obovate, abruptly acuminate, pubescent on the veins beneath, with 4-6 pairs of veins, 1½-3 in. long. China. Doubtful species.—*R. chlorophora*, Decne.=*R. globosus*.—*R. costata*, Maxim. Allied to *R. fallax*. Shrub, to 15 ft.: branchlets glabrous: lvs. elliptic- or ovate-oblong, crenately serrulate, with about 20 pairs of veins, pubescent beneath, 3-6 in. long; petiole very short: fr. black, $\frac{1}{2}$ in. across. Japan. S.I.F. 2:48.—*R. crenulata*, Ait. Evergreen shrub: lvs. oblong, obtusish, narrowly cuneate at the base, crenulate, glabrous, $\frac{3}{4}$ -1½ in. long: fls. in dense clusters in the axils of last year's lvs. Canary Isls. Tender.—*R. dumetorum*, Schneid. Spiny shrub, to 6 ft.: lvs. usually opposite, rhombic-lanceolate, acute at the ends, or elliptic, crenate-denticulate, pubescent at least on the veins beneath, $\frac{1}{2}$ -1½ in. long: fr. $\frac{1}{2}$ in. thick. W.

China. Var. *crenoserrata*, Rehd. & Wilson. Lvs. 1½-2½ in. long, more coarsely crenate-serrate. W. China.—*R. Erythrozylon*, Pall. Unarmed shrub, allied to *R. cathartica*: lvs. alternate, oblong-lanceolate to linear. Caucasus to Mongolia and Siberia. Hardy.—*R. globosa*, Bunge (*R. chlorophora*, Decne. *R. dahurica* var. *aprica*, Maxim.). Low rigid shrub: branchlets pubescent: lvs. opposite, obovate or broadly obovate, cuneate, pubescent, $\frac{3}{4}$ -2 in. long: fr. $\frac{1}{2}$ in. thick. N. and E. China.—*R. heterophylla*, Oliver. Shrub. to 5 ft. with often decumbent branches: branchlets pubescent; stipules persistent: lvs. alternate, ovate-lanceolate, $\frac{3}{4}$ -1½ in. long or broadly ovate, $\frac{1}{4}$ -½ in. long, puberulous on the veins beneath: fls. 5-merous. Cent. China. H.I. 18:1759.—*R. hybrida*, L'Her. (*R. Alaternus* × *R. alpinus*). Half-evergreen shrub, with alternate, oval-oblong, glossy lvs. Var. *Billardii*, Lav. Lvs. narrower, more remotely serrate. Half-hardy shrub, with handsome glossy foliage.—*R. infectoria*, Linn. Spiny spreading shrub, to 6 ft.: lvs. subopposite, oval or ovate to obovate, finely toothed, glabrous or pubescent on the veins beneath, $\frac{1}{2}$ -1½ in. long: fr. black. S.W. Eu.—*R. latifolia*, L'Her. Allied to *R. Frangula*: lvs. larger, elliptic-oblong, with 12-15 pairs of veins, 4-7 in. long: fr. $\frac{1}{2}$ -½ in. thick, changing from red to black. Azores. B.M. 2663. I.T. 3:106. G.W. 12, p. 342. Not hardy.—*R. leptophylla*, Schneid. Shrub, to 6 ft.: branchlets glabrous: lvs. opposite, obovate, short-acuminate, remotely denticulate, light green, glabrous beneath, 1½-3 in. long: fr. $\frac{1}{2}$ in. thick. Cent. and W. China.—*R. libanotica*, Boiss. Allied to *R. imeretina*; more spreading: lvs. oblong-obovate, crenate-dentate, pubescent beneath, with 10-15 pairs of veins: fr. $\frac{1}{2}$ in. across. Asia Minor.—*R. pumila*, Linn. Low, sometimes procumbent shrub, allied to *R. alpinus*, with smaller and shorter lvs., usually narrowed at the base. Eu., Alps. Hardy.—*R. Rostkornii*, Pritz. Shrub, to 5 ft.: branchlets glabrous: lvs. opposite, oblong-lanceolate, cuneate, crenate, pubescent beneath, $\frac{1}{2}$ -1 in. long: fr. $\frac{1}{2}$ in. across, with usually 2 seeds. W. China.—*R. rupestris*, Scop. Low, often procumbent shrub, about 3 ft. high, allied to *R. caroliniana*: lvs. ovate to oblong-obovate, thin, 1-3 in. long; umbels 1-3-fld. Alps of E. Eu.—*R. Sargentiana*, Schneid. Shrub, to 15 ft.: branchlets glabrous: lvs. alternate, oblong-elliptic, cuneate, acute or short-acuminate, crenate-serrate, sparingly hairy beneath, with 12-18 pairs of veins, 1½-5 in. long: fr. purplish black, $\frac{1}{2}$ in. across. W. China.—*R. saxatilis*, Linn. Low and dense, very spiny shrub, about 3 ft. high, allied to *R. cathartica*: lvs. opposite or alternate, oval or obovate, glabrous, about 1 in. long. Mountains of Cent. and S. Eu., W. Asia. Hardy. H.W. 3, p. 57.—*R. spatulifolia*, Fisch. Spiny shrub, to 6 ft.: lvs. alternate, elliptic-oblong to lanceolate, narrowed at both ends, finely toothed, glabrous or finely pubescent, $\frac{3}{4}$ -2 in. long: fr. black, slender-stalked. S. E. Eu., W. Asia.—*R. tinctoria*, Walst. & Kit. Closely allied to the preceding, but lvs. pubescent. Mountains of Cent. and S. Eu., W. Asia.—*R. utilis*, Decne. Shrub to 10 ft.: branchlets glabrous: lvs. opposite, elliptic-oblong, serrulate, light green, glabrous, with 5-8 pairs of veins, 2-5 in. long. Cent. and E. China.

ALFRED REHDER.

RHAPHIDOPHORA (Greek for *needle-bearing*; alluding to needle-like hairs). *Araceæ*. Climbing aroids, to be treated like Philodendron and Pothos. Species 60 in Engler, Pflanzenreich, hft. 37 (IV. 23B. 1908), of the East Indies, allied to Pothos, but distinguished by the presence of odd hairs in the intercellular spaces and by the two-loculed rather than three-loculed ovary. The garden plant *Pothos aureus*, sometimes provisionally referred here, is to be sought in Scindapsus. The generic name is sometimes spelled *Raphidophora*.

It is not known that any species of Rhaphidophora are in the American trade. *R. pertusa*, Schott (*Pothos pertusus*, Roxbg. *Scindapsus pertusus*, Schott), has large monstera-like lvs., with long and narrow side lobes and numerous holes in the blade. R.H. 1883, p. 561. *R. decursiva*, Schott, is a gigantic climber, with large pinnate lvs., the segms. or lfts. oblong-lanceolate-acuminate and strongly nerved: spathe yellowish. B.M. 7282. *R. Peëpla*, Schott, has entire oblong or elliptic-oblong lvs., with roundish or subcordate base: spathe yellowish.

RHAPHITHAMNUS (Greek, *rhaphis*, needle, and *thamnos*, shrub; referring to the needle-like spines). *Verbenaceæ*. Two evergreen small trees from Chile, with slender axillary spines, opposite, rather small, entire short-petioled lvs. and tubular lilac fls. axillary, solitary or in pairs on the spines, followed by bright blue globose berries: calyx tubular-campanulate, 5-toothed, persistent, becoming fleshy and inclosing the frs.; corolla tubular-funnelform, with short spreading unequally 5-lobed limb; stamens 4, didynamous, inclosed; ovary superior, 4-celled; style slender with 2-lobed stigma: fr. a fleshy drupe with two 2-celled and 2-seeded stones. The following species has recently been recommended as a hedge-plant for the warmer parts of the United States.

3371. *Rhamnus dahurica*. (× $\frac{1}{2}$)

R. cyanocarpus, Miers (*Citharéxylon cyanocarpum*, Hook. & Arn. *R. parvifolius*, Miers). Tree, to 20 ft.: young branchlets pubescent; spines slender, $\frac{1}{2}$ -1 in. long: lvs. sometimes in 3's, ovate, acute, rounded at the base, entire, glabrous above and glabrous beneath except bristly hairs on the midrib, $\frac{1}{4}$ - $\frac{3}{4}$ in. long: fls. lilac, slender, about $\frac{1}{2}$ in. long: fr. globose, bright blue, $\frac{1}{8}$ - $\frac{1}{2}$ in. across. Chile. B.M. 6849.—A handsome densely leafy shrub, particularly ornamental when studded with its bright blue frs. ALFRED REHDER.

RHAPIDOPHYLLUM (Greek, probably means *Rhapis-leaved*). *Palmaceæ*. BLUE PALMETTO. NEEDLE PALM. One species ranging from S. C. to Fla. It is a dwarf fan palm with erect or creeping trunk 2-3 ft. long, and long-stalked nearly round deeply and unequally cleft lvs. with about 15 segms.: spadices short-peduncled: spathes 2-5, entire, tubular, compressed, bifid, woolly: fls. minute, orange: fr. small, ovoid or obovate, woolly. The genus is closely allied to *Chamærops* and is distinguished by having the albumen not ruminant and by the bracts at the base of the branches of the spadix being few or none. The plant is said to produce suckers freely, like *Rhapis*. Cult. as in *Rhapis*.

Rhapidophyllum hystrix, the blue palmetto or needle palmetto, is the most beautiful and elegant of our native dwarf palms. It is very local in its distribution, being found in rich low soil both in Georgia and Florida, but it is everywhere rather rare. Its most striking characteristics are the long sharp black spines projecting in every direction from the dark fibers which cover the trunk. These spines, which are often a foot long, seem to protect the inflorescence, which before opening resembles a large white egg and which is imbedded among the spines. This palm bears staminate and pistillate flowers on separate plants. The woolly clusters of fruit or seeds are borne on short stems also surrounded by the sharp spines. This palmetto is easily transplanted. The leaves are dark shiny green, relieved by a pale silvery gray on the under surface. It is a very beautiful plant, and groups of it are striking. The stem is 2 to 3 feet high and the leaves rise to a height of 3 to 4 feet. (H. Nehrling.)

hystrix, H. Wendl. & Drude (*Chamærops hystrix*, Fraser). Fig. 3372. St. 2-3 ft., erect or creeping, proliferous, clothed with the fibrous remains of lf.-sheaths intermingled with long, erect spines: lvs. 3-4 ft., somewhat glaucous especially beneath, circular in outline, with numerous 2-4-toothed segms.; petiole triangular, rough on the margins; sheaths of oblique fibers interwoven with numerous strong, erect spines: spadix 6-12 in. long, short-peduncled: petals ovate, drupe $\frac{3}{4}$ -1 in. long. S. C. to Fla. I.H. 30:486.

JARED G. SMITH.

RHAPIS (Greek, *needle*: alluding to the shape of the leaves or perhaps the awns of the corolla). *Palmaceæ*, tribe *Sabaleæ*. Fan palms of very distinct habit, being among the few palms that produce suckers at the base, thereby forming bushy clumps.

Low palms, with leafy densely caespitose reedy sts. clothed with remains of the reticulate lf.-sheaths: lvs. alternate

and terminal, submembranaceous, connate or semi-orbicular, irregularly and digitately 3- to many-parted; segms. linear, cuneate, or elliptical truncate, entire, dentate or lobed; nerves 3 to many; transverse veins conspicuous; rachis none; ligule very short, semi-circular; petiole slender, biconvex, smooth or serrulate on the margins; sheath long, loosely fringed on the

3373. *Rhapis humilis*.

margin: spadices shorter than the lvs., slender-peduncled: rachis sheathed by deciduous bracts: branches spreading: spathes 2-3, incomplete, membranous: fls. yellow.—About 5 species, natives of China and Japan. This genus is distinguished from its near allies (for a list of which see *Licuala*) by the fls. being dioecious; corolla 3-toothed; anthers dehiscing extrorsely. The name *Rhapis* is commonly spelled and pronounced *Raphis*, but this is incorrect. They can be grown in temperate house with a night temperature of 55-60°. The soil should be good loam 3 parts, leaf-mold 1 part and sand 1 part. Prop. by imported seeds or by the freely produced suckers. Hardy in S. Calif. and S. Fla., and, in fact, the hardiest of all the palms with the exception of certain species of *Sabal* and *Chamærops*.

A. Sts. $1\frac{1}{2}$ -4 ft. high.

B. Lvs. with 5-7 segms.

flabelliformis, L'Her. (*R. Kwanivortsik*, Wendl.). Fig. 2739. Sts. $1\frac{1}{2}$ -4 ft. high: lvs. 5-7-parted; segms. linear, subplicate, ciliate-spinulose along the margins and midveins, truncate, erose at the apex; petioles serrulate along the margins. China, Japan. B.M. 1371. R.H. 1872, p. 230. A.G. 13:261. I.H. 34:13. G. 1:478; 23:614. Gn.M. 6:288. Var. *intermedia*, Hort., according to Siebrecht, has lvs. horizontal instead of somewhat erect. Var. *variegata*, Hort., has been offered.

BB. Lvs. with 7-10 or more segms.

humilis, Blume. Fig. 3373. Almost stemless, but producing a few short reed-like sts.: lvs. semi-circular; basal lobes directed backward; segms. rarely more than 10, spreading; petioles unarmed. China. A.F. 7:405; 22:475.

3372.

Young leaf of blue palmetto, not yet unfolded. ($\times\frac{1}{4}$)

AA. *Sts. becoming 8 ft. high.*

cochinchinensis, Mart. (*Chamærops cochinchinensis*, Lour.). *Sts.* often 6-8 ft.: lf.-segms. much plaited, oblong, obtuse; petioles short, straight and prickly. Cochin-China. Intro. by Franceschi, 1900.

N. TAYLOR.†

RHAPONTICUM (old Greek name for rhubarb, the same as occurs in *Rheum Rhaponticum*). *Compositæ*. Under this generic name at least one species is still catalogued, although the genus is now included as a section of *Centaurea*. Nine species are recognized in the group, extending from Morocco and Algiers to China. They are more or less thistle-like stout herbs, mostly or entirely perennial, with large solitary yellow, pink or purplish heads, the lvs. usually white-tomentose beneath: florets all equal and perfect: fr. 4-angled; pappus rough or feathery. Two species may be described here, under the genus *Centaurea*. *C. Rhaponticum*, Linn. (*Rhaponticum scariodum*, Lam.). Perennial, 2-2½ ft., with purplish fl.-heads: lvs. tomentose beneath, glabrous above, the lower ones ovate or cordate and finely toothed, petiolate, the upper ones sessile and oblong: outer scales of involucre scarious (dry). Alps, Switzerland. B.M. 1752. Appears not to be offered. *C. cynaroides*, Link (*R. cynaroides*, Less.). Perennial from the Pyrenees region: heads few and erect, purplish-fl.: lvs. large, oblong to ovate, attenuate at base, acuminate, the lower ones pinnately parted, the upper scarcely pinnatifid, all the lobes acutely toothed, more or less tomentose beneath: scales of involucre ciliate-serrate.—Listed abroad for outdoor planting.

L. H. B.

RHEEDIA (named after H. van Rheede 1635-1691). *Guttiferæ*. Trees, full of yellow sap, some of them with edible fruit.

Leaves rigid, leathery, lightly feather-veined: peduncles axillary or lateral, the male fascicled, the female fewer: fls. often small, polygamous-dioecious; sepals 2, often connate at the base; petals 4, decussately imbricated; ovary 3- (rarely 4-5-) celled: berry corticose and indehiscent.—About 30 species, Trop. Amer.

brasilienis, Planch. & Triana. Lvs. coriaceous, ovate or oblong-ovate, obtuse and narrowed at the base to a short petiole, apex obtuse or rather acute: fls. numerous, in axillary clusters, polygamous: berry obovate, short-beaked. Brazil and Paraguay.—Intro. into Calif.

edulis, Planch & Triana. Very smooth tree: lvs. lanceolate-oblong or oblong, acuminate, base acute or attenuate: fls., the fertile ones, axillary, the pedicels shorter than the fr.: drupe oblong, yellow. Cent. Amer.—Intro. into Calif.

macrophylla, Planch. & Triana. Lvs. broad-lanceolate or lanceolate-oblong, acute at both ends, leathery: fls. axillary, fascicled, 4-8; the pedicels twice the length of the fls.: berry ovate. S. Amer.

F. TRACY HUBBARD.

RHÈUM (*Rha* was the old Greek name for rhubarb). *Polygonacæ*. RHUBARB. Perennial (sometimes monocarpic) herbs grown for the large bold foliage and often interesting inflorescence; and one for the edible leaf-stalks.

Leaves mostly radical, large for the size of the plant, entire or divided, on stout thick petioles: sts. mostly strict and rising above the heavy foliage, often tall, making plants of striking habit: fls. perfect, small, greenish or whitish, pedicellate, in numerous paniced fascicles or racemes, the infl. elevated on stout mostly hollow scape-like sts., which are provided with sheathing stipules or ochreae (Fig. 3374); perianth 6-parted and spreading; stamens 9 or 6; ovary 3-angled and bearing 3 styles, ripening into a winged or sometimes nearly succulent achene.—Species about 25, Syria and Siberia to China, through the Himalayan region.

Aside from the common rhubarb, *Rheum Rhaponticum*, which is grown for the edible leaf-stalks, the species are little known in general cultivation. Few plants are more useful, however, for bold and striking foliage effects; and these effects are heightened by the towering flower-panicles. Most of the species are

3374. Ochrea or stipular sheath of rhubarb.—*Rheum Rhaponticum*. (×¼)

hardy and easy to grow, but they profit by a liberal winter mulch. Rheums are usually seen to best advantage against a heavy background of foliage or of rock (Fig. 1817, p. 1463). Even the common rhubarb is a useful ornamental subject when well placed. In order to secure large and fine foliage, the soil should be rich and moist. The species are propagated by dividing the root-masses, preferably in spring, leaving as much root as possible with each strong eye or bud.

The dried rhizomes of rhubarb are used medicinally. Several species afford the official product. The larger part of the dried rhubarb imported from the Orient is probably made from the crown or short stem (not the flower-stem) of *R. barbatum*. *R. Rhaponticum* is sometimes grown for its medicinal roots.

A. *St. or scape with large imbricating lvs. or bracts.*

Alexándra, Veitch. Tall, the fl.-sts. reaching 3-4 ft., bearing great pale yellow overlapping leaf-like rather obtuse bracts well above the dark glossy green and relatively small elliptic-ovate crown-lvs. Thibet, W. China. R.B. 35, p. 297. J.H. III. 61:297.—A striking plant of recent intro.

AA. *St. or scape without prominent imbricating foliage.*

B. *Foliage undivided, the margins of the lvs. nearly or quite entire.*

C. *Lvs. (at least on the fl.-stalks) acute or acuminate.*

Rhaponticum, Linn. (i. e., *Pontic Rha*, "Rhubarb of Pontus," a province of Asia Minor). RHUBARB. PIE-PLANT (in the U. S.). WINE-PLANT. Fig. 3374. Strong perennial, with thick clustered roots: petioles semicylindric, plane above: lf.-blades suborbicular, deeply cordate at base, undulate, about 5-ribbed, glabrous and shining above, pubescent on the veins beneath: panicles tall and narrow, somewhat leafy, densely flowered, the pedicels jointed below the middle, the fls. whitish: achene oblong-oval. In deserts and subalpine parts of S. Siberia.—Nearly everywhere grown in this country for the succulent acid petioles or leaf-stalks, which are used in early spring for pies and sauces. Wine is sometimes made from the juice. In France, known usually as an ornamental plant. There are several garden varieties. See *Rhubarb*.

undulatum, Linn. St. 4-5 ft., smooth: petioles semiterete, lightly channeled above, the lf.-blades ovate-cordate and strongly undulate (basal sinus not so deep as in *P. Rhaponticum*), 5-7-ribbed, glabrous above and puberulent beneath, the upper ones long: panicle narrow and leafy below, the pedicels jointed near the base: achene ovate or oval. Siberia.—Earlier and usually smaller than *R. Rhaponticum*.

cc. *Lvs. obtuse or essentially so.*

emodi, Wall. St. tall and leafy, 5-10 ft.: petioles semi-terete, somewhat concave above, the margins obtuse: lf.-blades large, ovate, cordate, obtuse, somewhat undulate, 5-7-ribbed, the under surface and the margin pubescent: panicles fastigiate branched, the fls. dark purple, pedicels jointed below the middle: achene large, ovate or oblong-oval. Himalaya, in alpine and subalpine regions.—Foliage has a coppery hue.

inopinatum, Prain. Small perennial of recent introduction: plant seldom more than 2 ft. high, the foliage clustered at the crown, the st. red and nearly leafless: lvs. orbicular-oval, gray-green, blades 6-9 in. long and nearly as broad, more or less blistered, not lobed but somewhat irregular-margined, obtuse, the petiole about 6 in. long and red-purple: infl. paniculate, bright red or crimson, produced in succession: fr. highly colored, the nutlets orbicular and 3-winged, nearly $\frac{1}{2}$ in. across.

2375. *Rheum officinale*, showing the foliage crown before flowering.

Thibet. B.M. 8190. G.C. III. 48:391.—A handsome small species, in condition nearly all summer, with attractive red-stalked and red-nerved foliage.

BB. *Foliage more or less lobed, the margins of the lvs. or segms. usually toothed or notched.*

c. *Lvs. shallowly or obscurely lobed.*

compactum, Linn. St. tall: petioles sulcate, plane above: lf.-blades thickish, broad-ovate, cordate, undulate and obscurely lobed, very obtuse, glabrous and shining above, the margin strongly toothed, the veins very prominent: panicle with drooping branches: achene large, dark-colored. Siberia to China.

cc. *Lvs. deeply lobed or evenly divided.*

palmatum, Linn. (*R. sanguineum*, Hort.). St. tall (5-6 ft.) and leafy: petioles subcylindrical, the margin rounded: lf.-blades broad, suborbicular and cordate, 3-5-ribbed, scabrous, deeply palmately lobed; the lobes ovate-oblong or lanceolate, acute, entire, dentate or pinnatifid: panicle leafy, with pubescent branches, the pedicels scarcely longer than the fls.: achene oblong-oval and subcordate. N. E. Asia. Var. *tanguticum*, Regel (*R. tanguticum*, Hort.). Lvs. more elongated and not so deeply lobed. G.Z. 20, p. 17. Var. *atrosanguineum*, Hort. (var. *floribus rubris*, Hort.), has a showy dark red panicle. Gn. 60, p. 10.

hybridum, Murr. Petiole long, canaliculate above and sulcate beneath: lf.-blades ovate, 3-5-ribbed, the base cuneate or scarcely cordate, incise-dentate, puberulent beneath: panicle lax, leafy: achene large, ovate.—Seems to be unknown wild. Perhaps a hybrid series between *R. palmatum* and *R. Raponicum* or *R. officinale*.

Colliniatum, Baill. Probably one of the *R. hybridum* series, with much-cut broad lobes that extend half the depth of the lf.-blade: fls. red. China.

officinale, Baill. Fig. 3375. Robust, with a short, branching st. or crown 4-10 in. high: lvs. very large, 1-3 ft. across, round-oval, more or less pointed or acuminate, hairy, 3-7-lobed, the lobes extending one-third or one-half the depth of the blade and sharply angled-notched: fl.-sts. 3-10 ft., much branched, bearing numerous greenish fls. that give a feathery effect to the panicle: achenes red, winged. Thibet and W. China, on high tablelands. B.M. 6135. R.H. 1874, p. 95. Gn. 36, p. 243; 48, pp. 199, 208; 59, p. 282. G.C. III. 55:328. G. 9:341; 18:428; 23, 452, 453.—Probably the best species of the genus for general cultivation

for ornament, making a striking foliage plant. It is from the short thick branching st. or caudex of this plant that most of the true officinal rhubarb is derived. Although known to the Chinese for centuries and the product long imported into Europe, the plant was not described botanically until 1872.

R. acuminatum, Hook f. & Thom. Dwarf plant (seldom exceeding 3 ft.), like a small form of *R. emodi*, with acuminate lvs., but fls. considerably larger: said to be an attractive plant in cult. but to die after flowering: sts. and infl. deep red-purple. B.M. 4877. G. 36:659.—*R. gunneroides*, Hort., is a garden hybrid, of German origin, between *R. emodi* and *R. palmatum*. Himalayas.—*R. nobile*, Hook f. & Thom. St. simple, 3-4 ft., densely clothed with imbricated downward-pointing bracts that conceal the short axillary peduncles: lvs. ovate-oblong or rounded, entire. When the fruit is ripe, the shingled bracts are torn away by the winds, leaving the long panicle exposed, and this may stand while another panicle grows from the crown and perhaps at some distance separated. Himalayas. R.H. 1876, p. 266. I.H. 22:209. G.C. II. 13:793. G.Z. 20, p. 104. A remarkable plant.—*R. Ribes*, Linn. 3-5 ft. lvs. 1 ft. across, cordate to reniform, the margins crisped or undulate, the blade puckered or blistered: fls. green, drooping: frs. about 1 in. long, oblong-cordate, narrow-winged, blood-red, showy. Asia Minor to Persia. B.M. 7591. "Ribes" or "Ribes" is its Arabic name.—*R. spiciforme*, Royle. Dwarf: lvs. thick, orbicular or broadly ovate: fls. white, in a dense spike rising about 2 ft. W. Himalaya.

L. H. B.

RHÉXIA (Greek, *rupture*, referring to its supposed properties of healing). *Melastomaceæ*. MEADOW BEAUTY. Low perennial often bristly herbs suitable for border and wild-garden planting.

Leaves opposite, sessile or short-petioled: fls. terminal, solitary or cymose; calyx-tube urn-shaped, adherent to the ovary below, and continued above it, persistent, 4-cleft at the apex; petals 4, oblique, falling early; stamens 8: caps. 4-celled, with 4- to many-seeded placentæ.—About 12 species, N. Amer.

Rhexia virginica is found wild in company with side-saddle plants (*Sarracenia purpurea*) and cranberries in the low meadows of Massachusetts. It is what would be called a bog-plant. It is a pretty, low-growing, tuberous-rooted plant blooming in summer and chiefly interesting as being one of few species of a genus belonging to a family almost wholly composed of shrubby plants from tropical countries, such as *Centradenia*, *Pleroma*, and *Medinella*. It increases by means of tubers and seeds, and under suitable conditions soon makes large clumps. Tubers potted in the autumn and kept in a coldframe force nicely in springtime. (T. D. Hatfield.)

A. *St. cylindrical.*

mariàna, Linn. A slender erect usually simple-stemmed plant with reddish purple fls. about 1 in. across, in loose cymes: lvs. short-petioled, oblong to linear-oblong, 1-1½ in. long, 2-5 lines wide, 3-nerved; anthers minutely spurred at the back. June-Sept. Pine barrens, N. J. to Fla., west to Ky. B.B. 2: 474.—Grows in drier places than *R. virginica*. It sometimes has white fls. and there is also a linear-lvd. form.

3376. *Rhexia virginica*. (× $\frac{1}{2}$)

AA. *St. angled.*B. *Petals yellow.*

littæa, Walt. *St.* becoming much branched, 1 ft. high: lvs. smooth, serrulate, the lower obovate and obtuse, the upper lanceolate and acute: fls. small, in numerous cymes. July, Aug. Pine-barren swamps, N. C. to Fla. and west.

BB. *Petals not yellow.*C. *Lvs. 6-10 lines long.*

ciliôsa, Michx. *St.* nearly simple, 1-2 ft. high: lvs. ovate, sessile or very short-petioled, 3-nerved: fls. violet-purple, 1-1½ in. across, short-pedicelled, in few-fld. cymes; anthers not curved and not spurred at the back. June-Aug. Swamps, Ind. to Fla., west to La.

CC. *Lvs. 1-2 in. long.*

virginica, Linn. Fig. 3376. Roots tuber-bearing: sts. about 1 ft. high, branched above and usually clustered, forming a compact, bushy plant: lvs. sessile, ovate, acute, rounded or rarely narrowed at the base, 1-2 in. by ½-1 in., usually 5-nerved: fls. rosy, 1-1½ in. across, in cymes; petals rounded or slightly retuse; anthers minutely spurred on the back. July-Sept. Sunny swamps, Maine to Fla., west to Mo. B.B. 2:474. B.M. 968.—This is one of the prettiest of the small wild fls. When transplanted, it seems to thrive as well in good clay loam as in peaty soils, although it sometimes grows in the latter.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RHIPIDODÉNDRON: *Aloe*.

RHIPIDÓPTERIS (from Greek for *division* and *Pteris* for *fern*). *Polypodiaceæ*. A tropical American genus of small ferns formerly classed under *Acrostichum* which it resembles in having the fertile lf.-blades entirely covered with sporangia. It differs in having the sterile lvs. dichotomously divided into linear lobes unlike any other fern.

peltâta, Schott (*Acrostichum peltatum*, Swartz). Rootstocks long-creeping: sterile lf.-blades 1-2 in. each way on slender stalks 2-4 in., repeatedly forked into very narrow divisions; fertile lf.-blades ¼-½ in. wide, circular, or somewhat 2-lobed. Mex. and W. Indies to Brazil.—A delicate and distinct plant, needing moisture all the year round especially in the air. Avoid unnecessary disturbances of roots. Use some partly decayed leaf-mold.

R. C. BENEDICT.

RHÍPSALIS

(Greek, *rhíps*, wicker-work). Includes *Lepismium*. *Cactaceæ*. Epiphytic plants of rather diverse form, sometimes grown in glasshouse collections of succulents and cacti.

Flowers very small, usually without tube; stamens and style very short: fr. small naked berries.—A genus of about 50 species, mostly confined to S. Amer. Excludes *Hariota* and *Pfeiffera* of *Cyclo*. Amer. Hort. Cult.

similar to epiphyllum and zygocactus. They are mostly fancier's plants and grown by collectors, for the interesting habit and characteristic kinds of branching.

A. *Bracts on ovary with hairs and bristles in their axils.*

1. *pilocárpa*, Löfgren. Branches terete, the axils bearing 10-15 white bristles: fls. wheel-shaped, 1 in. broad. Brazil.

AA. *Bracts on ovary naked.*B. *Ovary imbedded in the branch.*c. *Edges of joints winged.*

2. *squamulôsa*, Schum. (*Lepismium commune*, Pfeiff.). Somewhat branched, reaching a length of 2 ft.: branches very unequal in length, ½-1 in. thick, triangular, the angles winged: fls. 1-2, from the deep areoles, 5 lines long, greenish without, yellowish within. Brazil, Argentina. B.M. 3763.

CC. *Edges of joints not winged.*

3. *myosûrus*, Schum. (*Lepismium myosûrus*, Pfeiff.). Somewhat branched, a yard long: branches 3-6 lines thick, 3-4-angled, the angles not winged, the terminal branchlets generally acuminate, often tipped by a pencil of bristles: fls. solitary in the deep areoles, 4-5 lines long, rosy white: fr. red. Brazil. B.M. 3755.

BB. *Ovary not imbedded in the branch.*c. *Branches terete, slender.*D. *The branches of 2 kinds.*

4. *Sagliônîs*, Otto (*R. brachiata*, Hook. *Hariôta Sagliônîs*, Lem.). Fig. 3377. Reaching a height of 2 ft., richly branched: long or cereiform branches ½-1 ft. long; secondary or fruiting branches oblong-elliptic or short-cylindric, rounded at the ends, spirally or rarely verticillately arranged, sometimes weakly grooved, not more than ½ in. long: areoles with very scanty wool and

3377. *Rhipsalis Saglionis*. (× ¼)

2-4 short bristles, which on the end branches project as a little brush: fls. near the tops of the short branches, flat, $\frac{3}{8}$ in. diam., with 12 white lvs. with yellowish mid-stripe: berry white. Uruguay and Argentina. B.M. 4039.

5. *mesembrianthemoides*, Haw. (*Hariota mesembrianthemoides*, Lem.). Upright, the ends drooping, richly branched: long branches 4-8 in. long, 1 line diam.; fruiting branches 3-5 lines long, not more than 2 lines diam., spirally attached, thickly crowded: areoles sparsely woolly, with 1-2 bristles which project from the ends of the branches: fls. near the top of the joint, about 5 lines diam., formed of 10 white with yellow midstriped lvs.: berry white. Brazil. B.M. 3078.—Probably hardly more than a slender variety of the preceding species.

6. *gracilis*, N. E. Br. Branches terete, slender: fls. either terminal or lateral, minute. Passing in collections under the name of *R. penduliflora*.

DD. *The branches all alike.*

7. *grandiflora*, Haw. (*R. fundalis*, Salm-Dyck). Branching, cylindrical, rather stout, the branches reaching a height of 3 ft., with a diam. of more than $\frac{1}{2}$ in.; ultimate branchlets short, often verticillate: areoles depressed, bordered by a red line, sometimes in old branches bearing a bristle: fls. wheel-shaped, lateral on the branches, nearly 1 in. diam. Brazil. B.M. 2740.

8. *Cassytha*, Gaertn. Richly branching, pendulous, sometimes 10 ft. long; branches rarely 2 ft. long, 1-1 $\frac{1}{2}$ lines diam., pale green; ultimate branchlets spirally attached: areoles with sparse woolly hairs and frequently 1-2 minute bristles: fls. lateral on the terminal joints, 2-3 lines diam.: berry like that of the mistle-toe, 1-2 lines diam. Widely dispersed in Cent. and S. Amer., W. Indies, Mex., Mauritius, Ceylon, and Afr. B.M. 3080.

9. *virgata*, Web. Richly branching, pendulous, becoming a yard long; terminal branchlets hardly more than a line thick, spirally attached: areoles bearing sparse woolly hairs, with an occasional bristle: fls. lateral, 3-4 lines diam.: berry only 1 $\frac{1}{2}$ lines diam. Brazil.—Very much like the preceding.

CC. *Branches not terete.*

D. *The branches narrow, angled.*

10. *trigona*, Pfeiff. Richly branched, becoming a yard long: branches $\frac{1}{2}$ to nearly 1 in. diam., 3-angled: areoles sparsely woolly and bristly, the blooming areoles much more copiously so: fls. greenish outside, white within, 4 or 5 lines long. Brazil.

11. *paradoxa*, Salm-Dyck. Sparingly branched, 1-2 ft. long; branchlets 1-2 in. long and $\frac{1}{2}$ -1 in. diam., twisted at the joints, so that the angles alternate with the sides: fls. $\frac{3}{8}$ in. long, white. Brazil.

12. *pentaptera*, Pfeiff. Richly branched, 1-2 ft. long, 4-5 lines diam.: branchlets 2-5 in. long, 5-6-angled or almost winged: areoles in crenatures of the angles with scanty wool and an occasional bristle: fls. greenish white, 3-4 lines long; fr. white, bright rose-red above, crowned by the withered fl. S. Brazil, Uruguay, Argentina.

13. *rosea*, Lagerheim. Shrubby, more or less erect, usually 10 in. high: branches clustered, often hanging, 3-4-angled: fls. rare, large, 1 $\frac{1}{2}$ in. broad, rose-colored, fragrant. Brazil.

DD. *The branches usually flat or 3-angled, always broad.*

14. *rhombea*, Pfeiff. (*R. Swartziana?*, Pfeiff.). Branching, reaching a yard in length: joints green, lf.-like, crenate-oblong or rhombic, 1-5 in. long, $\frac{1}{2}$ -2 in. broad: fls. yellow, about 5 lines long. Brazil.

15. *pachyptera*, Pfeiff. (*R. alata*, Steud.). Erect, branching, reaching a height of nearly 3 ft.: joints flat, rarely 3-winged, rather thick, usually somewhat

concavo-convex, 3-8 in. long, blunt, 2-5 in. broad, often purple-red: fls. about 8 lines long, yellow with reddish tips. Brazil. B.M. 2820 (as *Cactus alatus*).

16. *Houlletiana*, Lem. (*R. Houllétii*, Lem.). St. richly branched, becoming 3 ft. or more long, 1-1 $\frac{1}{2}$ in. broad, often tapering to the round midrib for a considerable distance, then becoming again broad and lf.-like: fls. 8-9 lines long, yellowish white to yellow: berry red. Brazil. B.M. 6089.

R. angustissima, Web., *R. chloroptera*, Web., *R. Novæsi*, Löfgren, *R. Stimmeri*, Beauverd, and *R. Wrecklei*, Berger, are recent species occasionally seen in European collections, but not offered in American trade.

J. N. ROSE.

RHIZOPHORA (Greek, *root and bearing*, referring to the fact that the seeds germinate even while attached to the plant if they touch the ground). *Rhizophoraceæ*. Trees, with thick terete scarred branches, sometimes planted to hold seashores: lvs. opposite, petioled, thick, leathery, ovate or elliptic, entire, glabrous: peduncles axillary, di- or trichotomously branched, few-flid.: fls. rather large, leathery, sessile or pedicelled; calyx-limb 4-parted; petals 4; stamens 8-12; ovary semi-inferior, 2-celled: fr. leathery, ovoid or obconical, 1-celled, 1-seeded.—About 3 species, seashores of the tropics. *R. Mangle*, Linn. Shrub or tree reaching a height of 30 ft.: lvs. 2-6 in. long, leathery, elliptic or elliptic-obovate, obtuse: peduncles 2-3-flid.; fls. pale yellow; sepals lanceolate; petals linear, or nearly so, leathery, cleft at tip. Coast of Fla. and the tropics. It forms impenetrable thickets.

RHODANTHE: *Helipterum*.

RHODAZALEA: a name given in France to a hybrid (*R. Croixii*, Hort.) between a garden rhododendron and *Azalea mollis* (*Rhododendron sinense*). Another name for this hybrid is *Azaleodendron Crouxii*, Hort.

RHODEA: *Rohdea*.

RHODOCHITON (Greek, *red cloak*; alluding to the large rosy red calyx). *Scrophulariaceæ*. A free-flowering graceful vine with lvs. cordate, acuminate, sparsely and acutely dentate: fls. solitary, pendulous, axillary, long-peduncled; calyx conspicuous, large, membranous, broad bell-shaped, 5-cleft; corolla-tube cylindrical, the throat not personate, 5-lobed; lobes oblong, nearly equal: caps. dehiscent by irregular perforations.—One species, Mex.

volubile, Zucc. **PURPLE BELLS.** A vine with habit of maurandia, to which it is allied, but more vigorous and having curious, distinct purplish red fls. over 2 in. long on red peduncles: lvs. about 3 in. long. B.M. 3367. B.R. 1755. G.C. III. 53:310. G.M. 58:376. Gn.W. 12:449. I.H. 42:31. J.H. III. 43:563. R.H. 1910, p. 79.—Blooms the first season from seed and may be treated as a tender annual.

F. W. BARCLAY.

RHODODÉNDRON (Greek, *rhodon* and *dendron*, rose-tree; the *Rhododendron* of the ancient writers is *Nerium*). *Ericaceæ*. Including *Azalea* which most botanists consider inseparable from *Rhododendron*, but horticulturists may be inclined to retain *Azalea* for the deciduous species and to use the *Azalea* names given in parentheses. Highly ornamental woody plants, chiefly grown for their beautiful flowers and many species also for their handsome foliage.

Evergreen or deciduous shrubs, rarely trees: lvs. alternate, short-petioled, entire: fls. pedicelled, in terminal umbel-like racemes, rarely lateral, in 1- to few-flid. clusters; calyx 5-parted, often very small; corolla rotate, campanulate or funnel-shaped, sometimes tubular, with 5-, sometimes 6-10-lobed limb; stamens 5-10, sometimes more; anthers opening with pores at the apex; ovary 5-10-loculed; style slender with capitate stigma: caps. separating into 5-10 valves containing numerous

minute seeds.—About 350 species are known, distributed through the colder and temperate regions of the northern hemisphere; in Trop. Asia they occur in the mountains and extend as far south as New Guinea and Austral., the greatest segregation being in Cent. and W. China and the Himalayas; several species closely allied to those of the Malayan Archipelago are found in the Philippine Isls. but are not yet intro.; 16 species occur in N. Amer. The rhododendrons possess but few economic properties. The hardy close-grained

3378. A common hybrid form of garden rhododendron. ($\times \frac{1}{4}$)

wood of the arborescent species is used for fuel; also for construction and for turnery work; the lvs. of some species are used medicinally; those of *R. arboreum* and other species are believed to be poisonous to cattle. In India the fls. of various species are sometimes made into a subacid jelly. The honey obtained from the fls. is believed to be poisonous.

The rhododendrons belong to our most ornamental and most beautiful flowering shrubs and are often completely covered with their showy trusses of brilliantly and variously colored flowers and the evergreen species are attractive throughout the whole year with their handsome usually large foliage. They grow best in a peaty or porous loamy soil, which does not contain lime and always retains a sufficient amount of moisture; they like as a rule half-shaded positions. In regard to their culture and particular ornamental qualities, they may be divided into three horticultural groups: Evergreen rhododendrons, hardy deciduous azaleas, and Indian azaleas.

Evergreen rhododendrons.

Here belong the largest number of species comprising the two sections *Lepidorrhodium* and *Leiorrhodium*. Although most of the species are hardy only in warm temperate regions, there are many which are hardy at least as far north as Massachusetts. They are *R. maximum*, *R. catawbiense*, *R. caucasicum*, *R. brachycarpum*, *R. Metternichii*, *R. Smirnovii*, *R. mucronulatum*, *R. dahuricum*, *R. micranthum*, *R. lapponicum*, *R. ferrugineum*, *R. hirsutum*, *R. Kotschyi*, *R. carolinianum*, *R. minus*, and probably also *R. chrysanthum*, *R. Przewalskii*, *R. campanulatum*, *R. californicum*, *R. Ungernii*, and most of the small-leaved Chinese species. Somewhat more tender are *R. ponticum*, *R. niveum*, *R. Hodgsonii*, *R. Thomsonii*, *R. Anthopogon* and many of the recently introduced Chinese species, as *R. discolor*, *R. oreodoxa*, *R. decorum*. South of Philadelphia such

species as *R. cinnabarinum*, *R. glaucum*, *R. ciliatum*, *R. Fortunei*, *R. lepidotum*, *R. Collettianum*, and the Yunnan species, as *R. yunnanense*, *R. irroratum*, and *R. racemosum*, are probably hardy; also *R. arboreum*, *R. barbatum*, *R. Falconeri*, *R. Keysii*, *R. triflorum*, and *R. Wrightii* in very sheltered positions. Species like *R. Dalhousiae*, *R. Edgeworthii*, *R. Griffithianum*, *R. formosum*, *R. Maddonii*, *R. Nuttallii*, and *R. pendulum* stand only a few degrees of frost. The Javanese species, as *R. javanicum*, *R. jasminiflorum*, *R. Brookeanum* and *R. Lobbii* grow and bloom continually and stand no frost at all.

Variation in height.—Most of the species are shrubby; a few only, and these mostly Himalayan species, grow into small or medium-sized trees, attaining 60 feet in the case of *R. barbatum*, 40 feet in *R. grande* and *R. arboreum*, 30 feet in *R. Falconeri* and *R. maximum*. A number of northern and alpine species always remain dwarf, as *R. ferrugineum*, *R. hirsutum*, *R. lapponicum*, *R. virgatum*, *R. lepidotum*, *R. racemosum*, and others. A few Himalayan and Chinese species and most of the Malayan species are often epiphytal and grow on branches of large trees like orchids; e. g., *R. Dalhousiae*, *R. pendulum*, *R. Nuttallii*, *R. moupinense*.

Hybrid rhododendrons.—Many hybrids have been raised and they are now more extensively cultivated than the original species. The first hybrid was probably the one raised from *R. ponticum*, fertilized by a hardy azalea, probably *A. nudiflorum*; it originated about 1800, in the nursery of Thompson, at Mileend, near London, and was first described and figured as *R. ponticum* var. *deciduum* (Andrews, Bot. Rep. 6:379). Many hybrids of similar origin were afterward raised for which the name *Azaleodendron* has been proposed by Rodigas. The first hybrid between true rhododendrons was probably a cross between *R. catawbiense* and *R. ponticum*, but it seems not to have attracted much attention. It was by hybridizing the product of this cross with the Himalayan *R. arboreum* introduced about 1820 that the first plant was raised which became the forerunner of a countless number of beautiful hybrids. From the appearance of this cross, obtained about 1826, at Highclere, in England, and therefore called *R. altaclarensis*, the era of rhododendron hybrids is to be dated. Figs. 3378 and 3379 are common hybrid forms. A second era in the history of the rhododendron may be dated from the introduction of a large number of the beautiful Sikkim rhododendrons about 1850, among them species like *R. Griffithianum* which entered into the parentage of many of the most striking tender hybrids, and from the introduction of the Javanese species shortly afterward. A third era will perhaps be traced from the recent introduction of the Chinese rhododendrons.

Their place in ornamental planting.—Rhododendrons are equally effective and desirable as single specimens on the lawn as when massed in large groups, and are especially showy when backed by the dark green foliage of conifers, which at the same time afford a most advantageous shelter. The dwarf species, which are mostly small-leaved and flower at a different time, should not be grouped with the large-leaved ones, as they do not harmonize with them; however, they are exceedingly charming plants for rockeries or in groups with other smaller evergreens. It is certainly true that the rhododendrons have not yet received the attention they deserve. They are still far from being as popular as they are in England. The beautiful Himalayan species and their numerous hybrids are still almost unknown in this country, although without doubt they could be grown as well outdoors in the Middle and South Atlantic states as they are in England, if the right situation were chosen. Formerly it was considered impossible to grow the beautiful hardy hybrids in the New England

states, and it was first shown by the splendid collections of H. H. Hunnewell at Wellesley, Massachusetts (see A.F. 13:24-31 and Gng. 5:375-7), that, even in a trying climate, they can be grown to perfection if the proper situations are found and the right way of cultivation is followed.

Outdoor cultivation.—The selection of a suitable situation is of foremost importance. If possible the beds should be sheltered against drying winds and the burning sun by tall conifers, but the shelter should be always light and natural, as too much shelter by dense hedges or walls close to the plants is worse than no shelter at all. Any open well-drained soil which does not contain lime or heavy clay and has a moist and fresh subsoil will prove satisfactory. Where limestone or heavy clay prevails, beds must be specially prepared and filled with suitable soil. They should be at least 2 to 3 feet deep, or deeper when the subsoil is not porous, and in this case the bottom should be filled in about 1 to 2 feet high with gravel or broken stones for drainage. A mixture of leaf-mold or peat and sandy loam will make a suitable soil. In dry spells during the summer, watering is necessary if the subsoil is not very moist; it is most essential that the soil never becomes really dry. In autumn the ground should be covered with leaves, pine needles, hay, or other material to protect from frost. This mulch should be allowed to remain during the summer, especially when the plants are not large enough to shade the ground. An occasional top-dressing of well-decayed stable- or cow-manure will prove of much advantage. The ground should never be disturbed, as the roots are very near the surface. After flowering, the young seed-vessels should be removed. The rhododendrons are easily transplanted either in spring or in fall, especially if they grow in peat or turfy loam, and if a good ball of earth can be preserved in moving. They should be planted firmly, especially in porous, peaty soil, and thoroughly watered after planting. If they are carefully handled they are not much affected by transplanting, and tender kinds may be dug in fall, heeled-in in a frost-proof pit, and planted out

3379. A good plant of garden rhododendron in bloom.

again in spring. Potted and well-budded plants transferred in January into a temperature not exceeding 60° will develop in about six to eight weeks into very attractive and showy specimens for decoration.

Hardy varieties.—The following varieties have proved hardy in the vicinity of Boston and may be recommended for planting in similar climates and for experimental trial farther north. They are mostly hybrids of *R. catawbiense* with *R. maximum*, *R. ponticum*, *R.*

caucasicum and with some infusion of *R. arboreum* and perhaps a few other species. As in most of them the parentage of *R. catawbiense* is the most predominant, they are all usually called "catawbiense hybrids." Choice kinds are (those marked with an asterisk have proved the hardiest): *Album elegans*, bluish, changing to white; *Album grandiflorum*, bluish, changing to white, flowers larger, less spotted; *Alexander Dancer*, bright rose, paler in center; *Atrosanguineum*, rich blood-red; *August Van Geert*, bright carmine, spotted dark purple; *Bacchus*, crimson, large flowers; *Bicolor*, purplish pink, spotted; *Blandianum*, rosy crimson (H.F. 1859:153); **Bluebell*, bluish, with light purplish margin; **Boule de Neige*, white, early; **Caractacus*, deep crimson; *Charles Bagley*, cherry-red; **Charles Dickens*, dark red, spotted brown, one of the most striking red ones; *Cærulescens*, pale lilac; **Coriaceum*, white, spotted yellow, dwarf and free-blooming; *Crown Prince*, carmine, spotted greenish yellow; **Delicatissimum*, bluish, edged pink, changing to almost white, late (Gn. 63, p. 415); *Edward S. Rand*, rich scarlet; **Everestianum*, rosy lilac with crisped edges, excellent habit and very free-flowering (G. 26:103); **F. L. Ames*, white center, edged pink; **F. L. Olmsted*, pink; **Giganteum*, bright rose, large clusters; **Glennyanum*, white, suffused with pink (G.M. 44:355; 48:565); **Gomer Waterer*, bluish-pink; *Grandiflorum*, clear rose; *Guido*, deep crimson; *Hannibal*, rosy carmine; **Henrietta Sargent*, pink; *Henry W. Sargent*, crimson, large clusters; *H. H. Hunnewell*, rich crimson; *John Waterer*, dark crimson; *J. D. Godman*, carmine, distinctly spotted; **Kettledrum*, rich crimson; **King of Purples*, purple, spotted dark brown; *Lady Armstrong*, rose-red, paler in center, distinctly spotted; **Lady Clermont*, rosy scarlet; **Lady Frances Crossley*, salmon-pink; *Lady Gray Egerton*, delicate lilac, spotted greenish brown; **Lee's Purple*, purple; *Madam Carvalho*, bluish, changing to pure white; **Melton*, rich purple; **Mrs. C. S. Sargent*, similar to *Everestianum*, but pink; *Mrs. Milner*, rich crimson; **Norma*, pink; **Old Port*, plum-color; *Princess Mary of Cambridge*, white with purple margin; **Purpureum crispum*, lilac-purple, spotted greenish; **Purpureum grandiflorum*, purple, large clusters; *R. S. Field*, scarlet; *Ralph Sanders*, rich purplish crimson; *Rosa mundi*, white slightly flushed with yellow spots, dwarf (Gn. 63, p. 369); *Roseum elegans*, rosy lilac, dwarf; *Scipio*, rose with deep spot; **Sefton*, deep maroon, large clusters; *Wellsianum*, bluish, changing to white.

For greenhouse culture, the most successful way, especially with the taller-growing species, like *R. arboreum*, *R. Griffithianum*, *R. barbatum*, and *R. Falconeri*, is to plant them out in a porous peaty soil provided with good drainage. If grown in pots, a sandy compost of leaf-soil and peat, with an addition of some fibrous loam, will suit them. The pots, which should never be too large, must be well drained and the plants freely watered during the summer, while during the winter water must be carefully applied. The Himalayan species and their hybrids will do well in a cool greenhouse, where the temperature is kept a few degrees above freezing-point during the winter. The Javanese species and hybrids, however, on account of their continual growing and blooming, require a warmer greenhouse and must have a minimum temperature of 50° during the winter. They like a moist atmosphere and should be freely syringed in warm weather. In potting them, their epiphytal habit must be borne in mind, and the soil should consist mainly of good fibrous peat broken into pieces, with a liberal addition of sand and broken charcoal. The soil should never be allowed to become dry. They are readily propagated by cuttings with bottom heat in the warm propagating-house. The Javanese rhododendrons are especially valuable for their continual blooming during the winter and the brilliant color of their flowers. A large number of beautiful hybrids have been raised; the following are a

small selection of them: *Balsaminæflorum*, with double pink flowers (Gt. 37, p. 265. G.C. II. 18:230; III. 12:769. J.H. III. 43:151. G.Z. 27:241); *Balsaminæflorum album*, with double white flowers (Gn.W. 5:373); *Balsaminæflorum aureum*, with double yellow flowers; *Brilliant*, brilliant scarlet; *Ceres*, tawny yellow (Gn. 41:845); *Diadem*, orange-scarlet; *Duchess of Connaught*, vermilion-red; *Duchess of Edinburgh*, scarlet with orange-crimson (F.M. 1874:115); *Eos*, scarlet-carmine (G.C. III. 19:327); *Exquisite*, large light fawn-yellow flowers (Gn. 56:62); *Favorite*, satiny rose; *Jasminiflorum carminatum*, deep carmine (Gn. 41:328); *Little Beauty*, flowers small, but bright carmine-scarlet (Gn. 56:242); *Lord Wolseley*, bright orange-yellow, tinted with rose at the margins; *Luteo-roseum*, flowers satiny rose, suffused with white, center light yellow (G. 33:313); *Maiden's Blush*, bluish, with yellowish eye (Gn. 16:394); *Princess Alexandra*, white, faintly blushed; *Princess Frederica*, yellow, faintly edged rose; *Princess Royal*, pink; *Rosy Morn*, bright pink (Gn. 42:164); *Taylori*, bright pink, with white tube (F. M. 1877:242); *Triumphans*, crimson-scarlet.

Propagation.—All rhododendrons are easily propagated by seeds, which are very small and are sown in spring in pans or boxes well drained and filled with sandy peat. Pots should be well watered previous to sowing. The seeds should be covered only a very little with fine sand or finely cut sphagnum, or merely pressed in and not covered at all. To prevent drying, a glass plate may be placed over the pan or some moss spread over the surface; this, however, must be taken off as soon as the seeds begin to germinate. The seeds also germinate very readily if sown on fresh sphagnum, but in this case they must be pricked off as soon as they can be handled. In any case, it is of advantage to prick off the young seedlings as soon as possible, but if they are not sown too thickly they may remain in the seed-boxes until the following spring. The seedlings of hardy rhododendrons should be placed in coolframes and gradually hardened off; those of greenhouse species remain under glass. Rhododendrons are also sometimes increased under glass by cuttings of half-ripe wood taken with a heel, and if gentle bottom heat can be given after callusing it will be of advantage. They root, however, but slowly, except those of the Javanese kinds, which are mostly propagated in this way, since they grow very readily from cuttings. Layering is sometimes practised, especially with the dwarf and small-leaved species, but the layers usually cannot be separated until the second year. For the propagation of the numerous varieties and hybrids of hardy and half-hardy rhododendrons grafting is most extensively employed. *R. catawbiense* or seedlings of any of its hardy hybrids may be used as stock; *R. maximum* is also probably as good. In English and Belgian nurseries *R. ponticum*, which is inferior in hardiness, is mostly employed as a stock, but this often proves fatal if the grafted plants are transferred to colder climates. *R. arboreum* may be used for strong-growing varieties intended for cultivation in the greenhouse or South. Veneer- or side-grafting is mostly practised, and sometimes cleft- and saddle-grafting (see G.C. III. 24:425 and Figs. 3380, 3381). The leaves should be removed only partly and the stock not headed back until the following year. The grafting is usually done late in summer or early in spring in the greenhouse on potted stock without using grafting-wax, and the grafted plants kept close and shaded until the union has been completed. If large quantities are to be handled the plants are sometimes not potted, but taken with a sufficient ball of earth, packed close together and covered with moss. Covering with moss to keep the atmosphere moist is also of much advantage if the plants are potted.

Other experience with the evergreen rhododendrons. (B. M. Watson.)—Rhododendrons, in this article, mean more particularly *R. maximum* and the hybrid varie-

ties of *R. catawbiense*; in the main, however, the directions for the various operations apply to the azalea group and to many other members of the heath family.

Rhododendrons as a class are increased by seeds, layers and grafts, and occasionally by cuttings. Seeds should be sown under glass, between January 1 and March 15, in soil one-half peat and one-half pure fine sand, with good drainage. The seeds are small and

3380. Grafting of rhododendron. Saddle-graft at A; veneer-graft at B.

require no covering, the usual watering after sowing being quite sufficient. A thin layer of sphagnum over the surface of the seed-pan is good protection from the sun and keeps the soil evenly moist; it should be removed when germination begins. Seeds may also be sown on growing sphagnum, a thin layer being compactly spread above the seed-soil and drainage, and an even surface being secured by clipping. Seed-pans or flats of convenient size are used and they should be plunged in sphagnum still further to insure even moisture; the temperature of the house should be 45° to 50° F. Seedlings are prone to damp-off and should be pricked off into fresh soil as soon as they are big enough to handle; wooden pincers, made from a barrel hoop, are handy for this work. They are slow growers, and must be tended carefully. Keep under glass, well shaded until the weather is settled. Frames with lath screens make good summer quarters. Winter in pits and plant out in frames in peaty soil when large enough. Never let them suffer from dryness. It has been suggested that the seed of *R. maximum* might be planted on living moss under high-branched trees in swamps where the water does not collect in winter. (See Jackson Dawson, on the "Propagation of Trees and Shrubs from Seeds," in Transactions of the Massachusetts Horticultural Society, 1885, part I, page 145.) Layers probably make the best plants, and in the best English nurseries layering is the common method of propagation. In the United States layering in spring is preferable, but abroad it is practised in both spring and autumn. It is a slow process, but desirable for the hardy hybrids of *R. catawbiense*. Roots form on wood of almost any age; when removed the layers should be treated as rooted cuttings and carefully grown in well-prepared soil where water and shade are easily furnished. See *Layering*. See, also, G.F. 6:63 (1893) for an interesting account of layering large plants by burying them to the top.—Grafting is the common method of propagation, and is employed almost universally in continental nurseries. *R. ponticum* is the usual stock, a free grower and readily obtained from seeds. Attempts have been made to use *R. maximum* in American nurseries, because of the tenderness of *R. ponticum*, but no great progress has been made. It is asserted that the rate of growth is somewhat slower than that of the hybrids; this seems hardly possible, and it is to be hoped that further experiments will be made. *R. ponticum* should

be established in pots in spring and grafted under glass in autumn and early winter, using the veneer-graft (see *Grafting*, page 1362, Vol. III). Graft as near the root as possible and plant the worked parts below the surface when planting in the nursery or permanently. With these precautions, and an extra covering of leaves until the plant is established on its own roots, the defect of tenderness in this stock can be overcome. Nurse carefully the young grafted plants in frames until of sufficient size to be planted in the nursery rows. Figs. 3380 and 3381 illustrate two common methods of grafting rhododendrons and other woody plants. The details of the unions are shown in Fig. 3380, and the completed work in Fig. 3381. Statements are made that cuttings of half-ripened wood will strike, but it is not likely that this will ever prove a practical method of propagating *R. maximum* or the *R. catawbiense* hybrids; it might be worth while to experiment with wood grown under glass,

of humus. To nearly pure peat an admixture of sand is beneficial; the essential point is that all soils for these plants must be fine. The beds should be prepared in autumn and left to settle all winter, due allowance being made for shrinking. In spring level off to the grade of the adjacent land and do not leave "rounded up." A bed higher at the center than at the sides perhaps makes a better display of the plants, but is more likely to dry up and does not catch all the water possible from occasional showers. It is generally conceded that lime soils and manures containing lime, e.g., wood-ashes and bone-meal, are injurious to rhododendrons; in limestone regions it is undoubtedly advisable to substitute, for the natural soil, others which are free from this objectionable element.

Plant rhododendrons in spring when weather is settled and the March winds have passed. If the ball of roots is dry, soak well before setting. Plant closely, so that the tops are only 10 to 12 inches apart and pay particular attention to "facing" them, i. e., see that the best side is facing the most important point of view, and that all are faced alike. Grafted plants should, if possible, have the worked portion below the surface. Do not plant in autumn. Plants grown on the premises may be transplanted in favorable weather in summer if great care is taken to prevent the roots suffering from dryness. In planning the original border it is well to leave room for extension: when planted, as described above, the beds can be enlarged at intervals of four or five years, or new beds made from the old stock. Place the beds so that the glare of the midday sun is screened both summer and winter, and avoid situations where there is any interference, owing to trees or buildings, with a naturally good condition of the soil in respect to moisture. If permanent protection is desired, use conifers, particularly the hemlock, in preference to deciduous trees. Good positions for beds may be found along

3381. Saddle-graft at A; veneer-graft at B. (For comparison with Fig. 3380.)

particularly with some of the smaller-leaved evergreen kinds.

As to cultivation, the point on which successful American growers of rhododendrons now insist is that the water-supply shall be sufficient. (See H. H. Hunnewell, in *G.F.* 3:201, 1890.) To effect this: (1) make the soil deep and fine, using materials like peat, leaf-mold, well-rotted manure and yellow loam, all of which are retentive of moisture; (2) plant in masses, at any rate while young, so that they may protect each other and prevent evaporation; (3) give the bed a northern exposure or a situation where the force of the midday sun is broken; (4) do not plant under or near trees like elm, oak, or maple, which make undue inroads on the natural water-supply, nor so near buildings that the border is sheltered from rain or overdrained by cellar walls; (5) mulch with leaves summer and winter, protect from wind and sun with evergreen boughs in winter and in summer give heavy watering whenever the weather is excessively hot or dry.

The planting-bed should be prepared by excavating to the desired dimensions and at least 3 feet deep. The poor material should be discarded, but the good soil can be replaced, adding enough peat and the like (see above) to make good that which was rejected; all should be thoroughly and carefully mixed. Peat, although excellent, is not necessary. Yellow loam or hazel loam, if not too sandy, is equally good and is improved by additions

the edges of ponds and streams, and in reclaimed meadows, with their cool moist soil, but keep aloof from any ground where the water collects in summer or winter. Beds, or even single plants, if sizable, may be introduced into open spaces in woodlands if the precautions noted above are observed and plenty of air and light are obtainable. It is somewhat difficult to combine rhododendrons and many deciduous shrubs, among which are the azaleas, their near relatives. A background of dark green conifers seems most appropriate. Mountain laurels, *Pieris floribunda*, *Leucothoe Catesbaei*, and *Daphne Cneorum* are proper companions, but at times these seem better apart. Our native lilies, *L. superbum* and *L. canadense*, are good associates and thrive under the same conditions. In hot, dry weather water should be given, not daily in dribbles, as lawns are sprinkled, but in quantity, enough at one time to soak the border to the depth of the soil, but at comparatively infrequent intervals, once a week or so. The bed should also be mulched with leaves, or other material, to prevent evaporation; grass clippings are serviceable, but should not be used in large quantities at any one time or else they will heat. Leaves make good winter protection, which should be given just before cold weather,—in eastern Massachusetts, between Thanksgiving and Christmas. Let the bed be covered to the depth of 10 to 12 inches, well worked in beneath the foliage but not over it. In spring dig as much as pos-

sible of this material into the ground, reserving a part for the summer mulch. Shelter the tops with evergreen boughs, the butts driven into the earth a foot or more; in windy positions a temporary board fence is useful.

Experience at Rochester, New York (John Dunbar).—About fourteen years ago, rhododendrons were planted in the Rochester City Parks in beds excavated to a depth of 2 to 2½ feet (sandy soil containing lime removed), and filled with humus or soil of a peaty nature from an adjacent swamp. Cow-manure was mixed liberally in the surface. Rhododendrons planted in this preparation began to root immediately, grew with vigor, and flowered splendidly. About 20,000 square feet have been planted to rhododendrons in this way with unfailing success. A ¾-inch-pipe water-system is connected with all of the beds, with faucets at convenient points, and the plants are thoroughly watered in the growing season, and are never permitted to enter the winter with dry roots. The natural drainage is perfect. Rhododendrons will not tolerate stagnant moisture at their roots. They are thoroughly protected by the lay of the land from the west, northwest, and north winds, but are completely exposed to the south, summer and winter, and with the exception of a heavy mulching of leaves, spread over the beds in the autumn, they receive no other protection. The lace-fly became a very serious pest some years ago. The colonies of nymphs feed on the under side of the leaves and the foliage presents a sickly yellow appearance, as if attacked by red-spider. This is promptly destroyed and kept under control by two sprayings of Ivory soap during the growing season, using it in the proportion of five bars of soap to one hundred gallons of water.

The following are hardy at Rochester in a normal winter: *Catawbiense*, *Catawbiense album*, *Anna Parsons*, *Album elegans*, *Album grandiflorum*, *Alexander Dancer*, *Amarantinora*, *Atrosanguinea*, *Bertha Parsons*, *Boule de Neige*, *Caractacus*, *Charles Dickens*, *Cerulescens*, *Daisy Rand*, *Delicatissimum*, *Dr. Torrey*, *Edward S. Rand*, *Everestianum*, *F. D. Godman*, *F. L. Ames*, *Flushing*, *General Grant*, *Glenyanum*, *Guido*, *Henrietta Sargent*, *Henry Probasco*, *H. W. Sargent*, *Ignatius Sargent*, *J. R. Trumpy*, *Kissena*, *Kettledrum*, *Lady Armstrong*, *Macranthum*, *Maximum*, *Maximum superbum*, *Maximum Wellisianum*, *Mrs. C. S. Sargent*, *Mrs. Harry Ingersoll*, *Mrs. Henry S. Hunnewell*, *Mrs. Milner*, *Old Port*, *President Lincoln*, *President Roosevelt*, *Roseum pictum*, *Roseum elegans*, *Samuel B. Parsons*, *Scipio*, *Senator Charles Sumner*, *Sherwoodianum*.

The following are liable to severe injury in a very cold winter: *Blandyanum*, *Beauty of Surrey*, *Charles S. Sargent*, *Charles Bagelay*, *Giganteum*, *Hannibal*, *H. H. Hunnewell*, *James Bateman*, *James MacIntosh*, *J. Marshall Brooks*, *John Waterer*, *Lady Clermont*, *Lady Gray Egerton*, *Madame Carvalho*, *Meteor*, *Marchioness of Lansdowne*, *Mrs. John Clutton*, *Ralph Saunders*, *Rosabel*, *Stella*, *The Queen*.

The following species and hybrids are hardy: *R. arbutifolium*, *campanulatum*, *cavasicum pictum*, *carolinianum*, *dahuricum*, *ferrugineum*, *hirsutum*, *Metternichii*, *mucronulatum*, *myrtifolium*, *Smirnovii*.

Hardy deciduous azaleas.

These include the species of the sections *Pentathera* and *Rhodora* and some of the section *Tsutsutsi*, and the hybrids known as Ghent azaleas. Most of them are hardy, but in the North and in exposed situations a protection with brush, hay, or mats should be given in winter, to protect the flower buds from sudden changes of temperature.

In the open, the flowering period of hardy azaleas extends from April to July. First comes *R. canadense*, *R. rhombicum*, and *R. Vaseyi*; then *R. nudiflorum* and *R. japonicum*, followed by *R. luteum* and *R. calendulaceum* and nearly at the same time, *R. Schlippenbachii* and *R. Albrechtii*; somewhat later, *R. occidentale*, and last, *R. arborescens* and *R. viscosum*. One of the most beautiful is the American *R. calendulaceum*, which is hardly surpassed in the brilliancy and abundance of its flowers by any of the Ghent hybrids. There may also be mentioned the few species of true rhododendrons with deciduous foliage, as *R. mucronulatum* and *R. dahuricum*, which are the very earliest to bloom, and the hardy deciduous Indian azaleas, as *R. poukhanense* and *R. Kaempferi*, which flower with *R. Vaseyi* and *R. nudiflorum*. Azaleas are easy to transplant, either in

early spring or in early autumn, when the year's growth has ripened. If desired, they may be planted for decorative purposes in early spring, in beds, without injuring the abundance or brilliancy of the flower, and afterward removed to give space for other decorative plants, and planted carefully in nursery beds, where they remain till next spring; and so on every year. Especially the hybrids and varieties of *R. japonicum* (*Azalea mollis*) are often and easily forced for winter-flowering. If intended for early forcing, they should be grown in pots, and care taken to allow them to finish their growth as early as possible; for later forcing, after Christmas, they may be potted in fall, or even just before bringing them into the forcing-house. With a temperature of 50° to 55° at night, they will bloom in about six weeks. The Ghent azaleas are grown in great quantities in the Low Countries and in Germany for export to America; it is usually more profitable to buy this stock each fall than to attempt to raise it in this country, where labor is high-priced and the climate dry and hot.

Propagation is usually by seeds sown in early spring in frames or pans, in sandy peat, without covering, and kept moist and shady. When the seedlings appear they should have air and a daily syringing. In autumn they are transplanted into boxes or frames, in sandy, peaty soil. The seeds germinate very readily sown in cut sphagnum, but ought to be pricked into boxes as soon as they can be handled. The second year the seedlings should be planted out in beds, sufficiently wide apart to allow a growth of two years. Long upright branches should be shortened, to secure well-branched plants. The named varieties are grafted on any of the common species, usually by veneer-grafting in autumn in the greenhouse, on potted stock. They may also be increased by cuttings of mature wood 2 to 3 inches long, taken with a heel late in summer, and placed in sand under glass. Layers usually require two years to root sufficiently; they are made in spring, and the buried part inclosed in moss.

Many hybrids, known as Ghent azaleas or *Mollis* hybrids (*R. Morteri*, Sweet, *Azalea Morteriana*, Spae, *A. gandavensis*), are in cultivation. They have originated chiefly from crosses of *R. sinense*, and later *R. japonicum*, with *R. luteum*, *R. calendulaceum* and *R. nudiflorum*, also in some cases with *R. occidentale* and *R. viscosum*. Some good varieties are the following:

Single-flowered varieties: *Albicans*, *Admiral de Ruyter*, *Alladarensen* (R.B. 28:27); *Anthony Koster*, *Comte de Gomer* (R.B. 1:9. F.M. 1879:367); *Daviesi* (Gt. 42:1307); *Directeur Charles Baumann*, *Fragrans* (J.H. III:49:489); *Géant des Batailles*, *Hilja*, *Louis Hellebuyck* (F.S. 19:2019); *Marie Verschaffel*, *Morteri*, *Princesse d'Orange*, *Sanguinea*, *Tsarine* (R.B. 20:277); *Van Dyck*, *Viscosa floribunda*.

Double-flowered varieties: *Arethusa*, *Bijou de Gandbrugge* (F.S. 19:2024); *Louis Aimé Van Houtte* (F.S. 19:2022); *Madame Mina Van Houtte* (F.S. 19:2021); *Murillo* (R.B. 19:232); *Phebe* (R.B. 19:232); *Raphael de Smet*, *Virgile* (R.B. 19:232. G.W. 15, p. 493).

Indian azaleas.

This group contains *R. indicum* and other species of the section *Tsutsutsi* and the hybrids of them. They are well-known evergreen shrubs, in the North requiring cultivation in the greenhouse during the winter, but some, as *R. Kaempferi* and *R. poukhanense*, have proved perfectly hardy in the neighborhood of Boston; also *R. ledifolium* and *R. linearifolium* will stand many degrees of frost in somewhat sheltered positions. Indian azaleas are rarely increased by seeds, which may be sown in the greenhouse in the same way as with the former group. Usually they are propagated by cuttings or grafting. The cuttings root best when made in August from half-ripened wood, and placed in sand under a frame, with gentle bottom heat. Choicer varie-

ties are usually increased by veneer- or tongue-grafting, either in winter or in July and August on vigorous-growing varieties raised mostly from cuttings. Grafting on rhododendron is now used in some German nurseries with very good results. The best soil for azaleas, if grown in pots, is a sandy compost of half peat and half leaf-soil, with an addition of good fibrous loam. It is essential to plant them firmly, and to give very good drainage. The base of the stem should be just above the surface. The best time for repotting is after flowering, when the new growth commences. During the summer, they should be kept in a coldframe or in the open in a sheltered spot, with the pots plunged in the soil, or planted out in prepared beds, where they make a very vigorous and healthy growth. In September they should be repotted and transferred to the greenhouse. They must have plenty of water and free syringing during the hot months. The natural flowering time is from April to June, but in the greenhouse, azaleas may be had in flower from November till June. Against the red-spider and thrips, from which the azaleas are liable to suffer if the air is too dry, free syringing with water is the best remedy. Most of the plants used for forcing in this country are imported from Holland, Belgium, and Germany. Formerly azaleas were kept in summer in shade or partial shade, but now it is the custom of the best growers to give them full exposure to the sun, either planted out or in the pots plunged to the rim in ashes or other good drainage material; in the latter case a top-dressing of 2 or 3 inches of old cow-manure is very beneficial. The only American treatise is Halliday's "Treatise on the Propagation and Cultivation of Azalea Indica," Baltimore, 1880.

Some of the best varieties of Indian azaleas are the following (for a completer account, see August Van Geert, "Iconographie des Azalées," abbreviated here as Ic. Az. 20):

Single-flowered: *Antigone*, white, striped and spotted violet (R.B. 7:241. Ic. Az. 3); *Apollo*, vermillion (Ic. Az. 20); *Charmer*, rich amaranth, very large (F.M. 5:303, 304, 1); *Comtesse de Beaufort*, rich rose, blotched deep crimson; *Criterion*, rich salmon-pink, bordered white and blotched crimson (F.S. 8:796. F. 1849:137); *Diamond*, white, blotched dark crimson (F.S. 21:2233, 2234); *Duc de Nassau*, rich rosy purple, very free and large; *Easter Greetings*, small, flower often semi-double, crimson, very free-flowering; *Éclatante*, deep crimson, shaded rose; *Emil Liebig*, pink; *Fanny Ivery*, deep salmon-scarlet, blotched magenta (F.M. 10:542); *Fielder's White*, pure white, early (A.F. 13:1169); *Flambeau*, rich, glowing crimson (Gn. 16:242, 4); *Fuerstin Bariatinsky*, white, striped red (Gn. 16: 242. Ic. Az. 13); *Haerens' Lorraine*, small bright pink flowers, very floriferous; *Hexe* (Firefly), deep crimson, "hose in hose," small fl. very free-flowering (R.B. 31:49); *Jean Vervane*, salmon, striped, bordered white (R.B. 2:145. Ic. Az. 11); *John Gould Veitch*, lilac-rose, bordered and netted white, striped crimson (F.S. 20:2071, 2072); *La Victoire*, reddish, white toward the edges, spotted maroon-crimson; *Louise von Baden*, pure white, sometimes speckled pink (F.S. 17:1796. F.M. 3:158); *Madame Charles Van Eeckhaute*, pure white, with crisped edges; *Madame L. Van Houtte*, scarlet-rose, bordered white (F.S. 23:2383. Ic. Az. 5); *Marquis of Lorne*, brilliant scarlet, very fine; *Miss E. Jarret*, pure white, with crisped edges (R.B. 14:213); *Mrs. Turner*, bright pink, bordered white, spotted crimson (F.S. 8:451. Gn. 56, p. 306); *Mons. Thibaut*, orange-red; *Perle de la Belgique*, large, pure white; *President Victor Van den Hecke*, white, striped and speckled crimson, with yellow center (F.S. 15:1567, 1568); *Princess Alice*, pure white, one of the best; *Princesse Clementine*, white, spotted greenish yellow; *Professor Wolters*, pink, with amaranth blotch; *Reine des Pays-Bas*, rich violet-pink, bordered white (I.H. 13:479); *Roi de Hollande*, dark

blood-red, spotted black; *Sigismund Rucker*, rich rose, bordered white, blotched crimson, very showy (F.S. 19:2010, 2011. Ic. Az. 31); *Stella*, orange-scarlet, tinged violet; *Wilson Saunders*, pure white, striped and blotched vivid red.

Double-flowered: *Alice*, deep rose, blotched vermillion (I.H. 23:244); *Baron N. de Rothschild*, rich purple-violet, large (F.S. 23:2477, 2478); *Bernard André*, dark violet-purple, large; *Bernard André alba*, white (I.H. 17:15. Ic. Az. 19); *Borsig*, pure white; *Charles Leirens*, dark salmon, blotched dark purple, good form and substance (F.S. 19:1971, 1972); *Charles Pynaert*, salmon, bordered white (R.B. 10:25); *Chicago*, deep carmine, bordered white, large; *Comtesse Eugenie de Kerchove*, white, flaked red-carmine; *Deutsche Perle*, pure white, early (R.B. 21:85. R.H. 1886:516. Gn. 33:460. Ic. Az. 25); *Dominique Vervane*, bright orange;

3382. *Rhododendron mucronulatum*. (× 1/4)

Dr. Moore, deep rose, shaded white and violet, very fine (R. B. 11:61); *Égebrechtii*, bright crimson; *Empereur du Brésil* (Emperor of Brazil), rich rose, banded white, upper petals marked red (Ic. Az. 15); *Ernest Eeckhaute*, deep carmine, very double; *François de Vos*, deep crimson (I.H. 14:512. Ic. Az. 14. F.M. 8:443); *Frau Herm. Seidel*, white, striped red; *Helene Thelemann*, rosy pink, free-flowering; *Imbricata*, white, sometimes flaked rose (I.H. 24:281. F.S. 22:2284, 2285. F. 1876, p. 201); *Impératrice des Indes* (Empress of India), salmon-rose, bordered white and spotted dark carmine (F.M. 18:357. Ic. Az. 21. F. 1879:97); *Johanna Gottschalk*, white; *John Liewelyn*, soft pink; *Louise Pynaert*, white (R.B. 4:209); *Madame Camille van Langenhove*, white, striped with rose, very double; *Madame Iris Lefebvre*, dark orange-carmine, shaded bright violet and blotched brownish red (F.S. 18:1862, 1863); *Madame Jos. Vervane*, large, pink and white, similar to *Vervaneana*; *Madame Petrick*, bright rose, very early; *Madame Van der Cruyssen*, pink, fine form (A.F. 12:1003); *Madeleine*, white, large, semi-double; *Niobe*, white, fine form; *Pharailde Mathilde*, white, spotted cherry-red (R.B. 13:145); *President Ghellinck de Walle*, bright rose, upper petals spotted yellow and striped crimson; *President Oswald de Kerchove*, pink, bordered white, blotched carmine; *Raphael*, white; *Sakuntala*, white, very free-flowering; *Simon Mardner*,

large, rose, very double and very early; *Souv. du Prince Albert*, rich rose-peach, broadly margined white, very free-flowering (F.M. 4:201. Ic. Az. 24); *Theodore Reimers*, lilac, large; *Vervæneana*, rose, bordered white, sometimes striped salmon (Gn. 52, p. 137. C.L.A. 5:146; 7:179. J.H. 31:423); *Vervæneana alba*, white (R.H. 1908:424); *Vuyisteksana*, deep crimson, "hose-in-hose."

The varieties now chiefly imported and considered the best for forcing are the following (those marked with an asterisk are adapted for early forcing):

Single-flowered: **Emil Liebig*, *Haerens' Lorraine*, **Hexe*, Professor Wolters.

Double-flowered: **EGgebrechtii*, *Empereur du Brésil*, *Ernest Eeckhaute*, **Frau Herm. Seidel*, **Helene Thelemann*, **Imperatrice des Indes*, *John Liewelyn*, **Madame Camille Van Langenhove*, *Madame Jos. Vervæne*, **Madame Petrick*, *Madame Van der Cruyssen*, *Niobe*, *Pharailde Mathilde*, **Pres. Oswald de Kerchhove*, **Simon Mardner*, **Vervæneana*.

Plants grown in Germany are preferred for early forcing, because they are grown in pots over summer before shipping, while the Belgian plants are grown in the open field. Generally the Belgian plants are grown more compact, while the German-grown plants are of looser, more naturally graceful habit. Some varieties, though much approved abroad, are rarely imported, because they do not travel well.

KEY TO THE GROUPS.

A. Foliage evergreen, glabrous, lepidote or tomentose, rarely deciduous and lepidote, not ciliate or ciliate and lepidote: stamens 5–20; ovary glabrous, lepidote or tomentose, not setose, sometimes more than 5-celled. Subgenus I. EURHODODENDRON

B. Lvs. lepidote: ovary lepidote; stamens 5–10.

Section 1. LEPIDORHODIUM. Species Nos. 1–16

BB. Lvs. glabrous or tomentose beneath, never lepidote, always persistent: ovary glabrous, glandular or tomentose; stamens 10–20.

Section 2. LEIORHODIUM. Species Nos. 17–28

AA. Foliage deciduous, rarely evergreen, pubescent, often strigose and ciliate, rarely glabrous, never lepidote: stamens 5–10; ovary setose, rarely glabrous, 5-celled. Subgenus II. AZALEA

B. Fls. from axillary buds, usually solitary; corolla rotate. Section 3. AZALEASTRUM. Species No. 29

BB. Fls. from terminal buds, 1 to many.

C. Terminal bud producing only fls., usually many-fld.: lvs. deciduous.

D. Stamens 5; corolla funnelform-campanulate or funnelform.

Section 4. PENTANTHERA. Species Nos. 30–38

DD. Stamens 7–10; corolla rotate-campanulate, deeply divided.

Section 5. RHODORA. Species Nos. 39, 40

CC. Terminal bud producing fls. and leafy shoots, 1–3-fld.; stamens 5–10; lvs. persistent or deciduous.

Section 6. TSUTSUTSI. Species Nos. 41–48

Subgenus I. EURHODODENDRON.

Section 1. LEPIDORHODIUM.

A. Corolla funnelform or campanulate; tube shorter or not much longer than lobes.

B. Fls. from a terminal bud, usually many.

C. Diam. of fls. $\frac{1}{2}$ – $\frac{3}{4}$ in.

D. Stamens and style longer than corolla, filaments glabrous; fls. white, small, in a many-fld. dense head.

1. micranthum

DD. Stamens and style shorter than corolla, filaments hairy below the middle; fls. usually pink; tube pubescent inside.

E. Style scarcely twice as long as ovary: lvs. $\frac{1}{2}$ –2 in. long.

F. Lvs. without hairs.

2. ferrugineum

FF. Lvs. ciliate

3. hirsutum

EE. Style at least 3 times as long as ovary: lvs. 1–3 in. long.

F. Shape of lvs. lanceolate-elliptic.

4. arbutifolium

FF. Shape of lvs. elliptic.

5. myrtifolium

CC. Diam. of fls. 1–2 in.; tube glabrous inside.

D. Style and stamens shorter than corolla-lobes: petioles about $\frac{1}{2}$ in. long.

E. Tube of corolla longer than lobes, corolla lepidote outside, spotted.

6. minus

EE. Tube of corolla shorter or as long as lobes; corolla glabrous outside, usually not spotted.

7. carolinianum

DD. Style exceeding the corolla-lobes: petioles about $\frac{1}{2}$ in. long.

E. Color of fls. yellow: lvs. glabrous.

8. Keiskei

EE. Color of fls. pink, rarely white. F. Lvs. ciliate or hairy on the midrib beneath: stamens longer than the corolla-lobes.

G. Midrib of lvs. pilose beneath; lvs. glabrous above: fls. rose-pink to purple.

9. Augustini

GG. Midrib of lvs. glabrous; lvs. setose above and ciliate, sometimes nearly glabrous: corolla white, spotted red.

10. yunnanense

FF. Lvs. never hairy: stamens somewhat shorter than corolla-lobes.

11. yanthinum

BB. Fls. from lateral buds usually crowded at the end of the branches, one or few from each bud.

C. Under side of lvs. glaucous and lepidote: fls. about $\frac{3}{4}$ in. across.

12. racemosum

CC. Under side of lvs. green and lepidote: fls. 1–1½ in. across.

- D. Margin of lvs. usually ciliate:
lvs. persistent.....13. *præcox*
DD. Margin of lvs. glabrous.
E. Lvs. obtuse or obtusish at the
ends, sometimes partly
persistent.....14. *dahuricum* [tum
EE. Lvs. acute at the ends, decidu-
ous: fls. larger.....15. *mucronula-* [florum
AA. Corolla with a cylindric tube thrice as
long as the lobes.....16. *jasmini-*

1. *micrânthem*, Turcz. Shrub, to 8 ft.: lvs. lanceolate or oblanceolate, obtuse or acutish, glabrous above, densely ferrugineous-lepidote beneath, $\frac{3}{4}$ – $1\frac{1}{2}$ in. long: fls. in dense many-fld. clusters, white, campanulate, $\frac{1}{4}$ – $\frac{1}{2}$ in. across, lobes oblong or oval, longer than tube; stamens longer than corolla, glabrous; style shorter than stamens; sepals lanceolate, ciliate, $\frac{1}{2}$ in. long. June, July. Manchuria to W. and Cent. China. B.M. 8198.—Very distinct species, resembling *Ledum* with its dense clusters of small white fls. and exserted stamens and with its small lvs. It has proved perfectly hardy at the Arnold Arboretum and is very floriferous even as a small plant.

2. *ferrugineum*, Linn. Shrub, 2 ft. high, glabrous: lvs. elliptic to oblong-lanceolate, acute, densely lepidote beneath, 1–2 in. long: clusters many-fld.; calyx-lobes short, obtuse; corolla funnelform-campanulate, with the tube about twice as long as limb, pink or carmine, about $\frac{1}{2}$ in. across. June–Aug. Mountains of Cent. Eu. L.B.C. 1:65. Gn. 29, p. 358. G. 8:610.—Dwarf, hardy shrub, handsome for rockeries. Var. *âlbum*, Sweet, has white fls.

3. *hirsutum*, Linn. Shrub, 3 ft. high, with hirsute branches: lvs. oval to oblong, ciliate, light green and glandular-lepidote beneath, $\frac{1}{2}$ –1 in. long: clusters many-fld.; calyx-lobes lanceolate, as long as ovary; corolla similar to that of the preceding, lobes shorter. June, July. Alps. L.B.C. 5:479. B.M. 1853. L.D. 6:425.—Much like the preceding, but usually thrives better in cult. and does not dislike limestone soil.

4. *arbutifolium*, Hort. (*R. daphnoides*, *R. Hammondii*, and *R. oleæfolium*, Hort. *R. Wilsonii*, Hort., not Nutt.). A hybrid of *R. ferrugineum* and *R. minus*. Dense shrub, 4 ft. high: lvs. elliptic to elliptic-lanceolate, acute at both ends, $1\frac{1}{2}$ –3 in. long: fls. similar to those of *R. ferrugineum*, but larger. June, July.—Of garden origin. Handsome hardy shrub, perhaps best known under the name of *R. Wilsonii*; this name, however, had been given previously to another hybrid between two Himalayan species and should not be used for this plant.

5. *myrtifolium*, Lodd. (*R. ovalifolium*, Hort. *R. ovatum*, Hort., not Hook.). Hybrid between *R. minus* and *R. hirsutum*, much like the preceding, but lvs. generally smaller and broader, less densely lepidote beneath, 1– $2\frac{1}{2}$ in. long, sometimes sparingly ciliate when young: fls. longer-pedicelled and calyx-lobes narrower and longer. June, July. L.B.C. 10:908.—Originated in the nursery of Loddiges.

6. *minus*, Michx. (*R. punctatum*, Andr. *R. Cuthbertii*, Small). Straggling shrub, to 10 ft.: lvs. elliptic to elliptic-lanceolate, acute at both ends, sometimes acuminate, glabrous above, glandular-lepidote beneath, $1\frac{1}{2}$ –4 in. long: heads about 6–8-fld.; calyx short; corolla funnelform-campanulate, about 1 in. across, rosy pink, the upper lobe spotted greenish, lepidote outside; tube nearly cylindric, longer than the ovate crisped lobes. June, July. N. C. to Ga. and Ala. B.M. 2285.—Fls. appear with or after the new lvs. Var. *Hárbisonii*, Rehd. Fls. larger, $1\frac{1}{2}$ in. across, in dense, about 10-fld. heads. Ga. Handsomer than the type.

7. *carolinianum*, Rehd. (*R. punctatum*, Small, not Andr.). Shrub, to 6 ft., usually low and compact: lvs. oval to narrow-elliptic, acutish or shortly and abruptly acuminate, broadly cuneate at the base, glabrous above, ferrugineous-lepidote beneath, often very densely so,

2–3 in. long: fls. in dense 5–10-fld. heads, broadly funnelform-campanulate, about $1\frac{1}{2}$ in. across, pale rosy purple or rarely whitish, not or only slightly spotted; tube gradually widened, as long or shorter than the ovate lobes, glabrous or nearly so outside. May, June. N. C. B.R. 37. G. 31:619 (as *R. punctatum*).—On account of its compact habit and larger fls. superior as an ornamental plant to the preceding.

8. *Keiskei*, Miq. Low, sometimes procumbent shrub: lvs. elliptic to lanceolate, acute, dull green above, lepidote beneath, $1\frac{1}{2}$ –3 in. long: clusters 2–5-fld.; calyx minute; corolla broadly funnelform, divided to the middle into rounded lobes, pale yellow, $1\frac{1}{2}$ in. across; stamens much exserted. May. Japan. B.M. 8300.

9. *Augustini*, Hemsl. Shrub, to 20 ft.: branchlets pubescent while young: lvs. elliptic-ovate to oblong-lanceolate or lanceolate, acute or acuminate, broadly cuneate at the base, pale green beneath and lepidote and hirsute on the midrib and petiole, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long: fls. 3–6; calyx-lobes short, ciliate; corolla broadly campanulate, $1\frac{1}{2}$ –2 in. across, pale purple or rosy pink, rarely nearly white; lobes much longer than tube; stamens as long or slightly shorter than corolla, style longer. Cent. and W. China. B.M. 8497. G.C. III. 52:4. F.S.R. 3:162. R.H. 1909, p. 18.

10. *yunnanense*, Franch. Shrub, to 6 ft.: lvs. elliptic-lanceolate, acute, cuneate at the base, with scattered stiff hairs above and on the margin, or sometimes nearly glabrous, pale green below and sparsely lepidote, $2\frac{1}{2}$ –3 in. long: fls. 3–8; calyx minute; corolla broadly funnelform, 2 in. across, white, the upper lobes spotted blood-red, lobes longer than tube; stamens about as long as lobes, style longer. May. S. W. China. B.M. 7614. G.C. III. 39:399; 46:68; 54:396. G. 32:69; 36:305. Gn. 78, p. 317. M.D.G. 1903:173. F.S.R. 2:360.

11. *yánthinum*, Franch. (*R. concinnum*, Hemsl. & Wilson and Hort., not Hemsl. *R. Benthamianum*, Hemsl. *R. atroviride*, Dunn). Shrub, to 10 ft.: lvs. ovate-elliptic, acute, rounded or sometimes broadly cuneate at the base, glaucescent and rather densely lepidote beneath, $1\frac{1}{4}$ – $2\frac{1}{2}$ in. long: fls. 3–6; calyx minute; corolla funnelform-campanulate, $1\frac{1}{4}$ in. long and as broad, purple or rosy purple, sometimes white, glabrous outside, tube about as long as lobes; stamens somewhat shorter than lobes, style longer. June. W. China. Var. *lepidánthum*, Rehd. & Wilson. Corolla lepidote and pubescent outside, dark purple: lvs. broader.

12. *racemòsum*, Franch. Shrub, to 6 ft.: lvs. elliptic to oval or obovate, obtuse or acutish, rounded or broadly cuneate at the base, glabrous above, glaucous below and lepidote, $\frac{3}{4}$ – $1\frac{1}{4}$ in. long: fls. 1–3, from axillary buds usually crowded at the end of the branches, sometimes along the branches; corolla funnelform-campanulate, $\frac{3}{4}$ in. across, rose-pink, lobes oblong, about as long as tube; stamens and style exserted. B.M. 7301. G.C. III. 12:63; 47:343. Gn. 42:320. G. 28:224. Gt. 57:1577, pp. 562, 563. G.W. 6, p. 43 (as *R. rigidum*); 14, p. 271. R.H. 1912, p. 134.—It flowers profusely when still very small.

13. *præcox*, Carr. Hybrid between *R. ciliatum* and *R. dahuricum*. Low shrub with persistent, elliptic or oval lvs., sparingly ciliate or glabrous, ferrugineous-lepidote beneath, 1–2 in. long: clusters few-fld.; calyx-lobes ovate, ciliate; corolla broadly funnelform, pale purple or lilac, $1\frac{1}{2}$ in. across. March, April. Of garden origin. R.H. 1868:210. Gn. 38:32; 59, p. 277; 61, p. 428; 71, p. 151. G.C. II. 17:295; III. 12:771. Gt. 50, p. 135; 56:1567. G.W. 5, p. 267. G. 35:109.—Less hardy than the following species, but handsomer. Here belongs also Early Gem, with larger pale lilac fls. and the lvs. somewhat more ciliate. G.C. II. 9:336.

14. *dahuricum*, Linn. (*Azalea dahurica*, Koch). Shrub, to 10 ft.: lvs. deciduous or sometimes partly

persistent, very short-petioled, oval to oval-oblong, obtuse at both ends, revolute at the margin, ferruginous-lepidote beneath, $\frac{3}{4}$ – $1\frac{1}{2}$ in. long: fls. 1–3 at the end of the branchlets; corolla rotate-funnelform, rose-colored, 1 in. across; stamens about as long as lobes, style longer. March, April. Siberia, N. China, Kamchatka. B.M. 636. L.B.C. 7:605. G.C. II. 17:295; III. 12:701; 53:51. Gn. 77, p. 18. G.W. 7, p. 415. Var. *sempervirens*, Sims (var. *atrovirens*, Edw.). Lvs. dark green, almost persistent: fls. violet-purple. B.M. 1888. B.R. 194. L.B.C. 16:1584. Gt. 53, pp. 267, 268. R.H. 1908, p. 198.

15. *mucronulatum*, Turcz. (*R. dahuricum* var. *mucronulatum*, Maxim.). Fig. 3382. Upright shrub, attaining 6 ft.: lvs. elliptic to oblong, acute at both ends, slightly crenulate, sparingly lepidote on both sides, bright green above, pale beneath, 2–3 in. long: fls. 3–6, short-pedicelled; corolla rotate-funnelform, divided to the middle into oval rounded lobes, rose-colored, $1\frac{1}{2}$ in. across. March, April. Manchuria, N. China, Korea, Japan. G.F. 9:65 (adapted in Fig. 3382). M.D. 1898:1.

3383. *Rhododendron arboreum*. ($\times \frac{1}{2}$)

B.M. 8304.—Hardy shrub valuable for its very early fls. (it is the earliest of all hardy rhododendrons) and for its handsome scarlet fall coloring.

16. *jasminiflorum*, Hook. Small shrub: lvs. subverticillate, obovate to oblong, acute, glabrous, lepidote beneath, $1\frac{1}{2}$ –3 in. long: clusters many-fl.; pedicels short; calyx minute; corolla almost salver-shaped, with the tube 2 in. long and with spreading limb, fragrant, white, blushed outside below the limb, the anthers forming a red eye; style shorter than stamens, included. Winter. Java, Malacca. B.M. 4524. I.H. 6:203. J.F. 1:41. G. 32:145.—A distinct species, very unlike other rhododendrons; it requires a warm greenhouse.

Section 2. LEIORHODIUM.

A. Under side of lvs. tomentose or pubescent.

B. Ovary tomentose: branchlets tomentose or nearly glabrous.

C. Corolla distinctly campanulate; lobes much shorter than tube; pedicels about $\frac{1}{2}$ in. long: tall shrub or tree, tender. 17. *arboreum*

CC. Corolla funnelform-campanulate; pedicels $\frac{3}{4}$ –2 in. long.

D. Lvs. acute at both ends.

E. Tomentum of lvs. beneath and of branchlets whitish or pale brown. 18. *Smirnovii*

EE. Tomentum of lvs. beneath and of branchlets deep brown.

F. Corolla 5-lobed, spotted greenish. 19. *caucasicum*

FF. Corolla 5–7-lobed, spotted purple. 20. *Metternichii*

DD. Lvs. obtuse or obtusish at both ends. 21. *brachycarpum*

BB. Ovary and branchlets glabrous. 22. *campanulatum*

AA. Under side of lvs. glabrous or pubescent only when young. (tum)

B. Plants with coriaceous persistent lvs.

C. Ovary glabrous or glandular only.

D. Pedicels puberulous; ovary glandular; stamens 10. 23. *ponticum*

DD. Pedicels glabrous; ovary glabrous; stamens 13–16. 24. *sutchuenense*

CC. Ovary tomentose or pubescent.

D. Calyx-lobes much shorter than ovary.

E. Pubescence of ovary rusty hirsute; pedicels glabrous. 25. *californicum*

EE. Pubescence of ovary glandular; pedicels pubescent. 26. *catawbiense*

DD. Calyx-lobes nearly as long as ovary: lvs. acute at both ends. 27. *maximum*

BB. Plants with rather thin lvs. falling off the second spring: hybrids between this and the following section 28. *azaleoides*

17. *arboreum*, Smith. Fig. 3383. Large shrub or tree, attaining 40 ft.: lvs. oblong to lanceolate, acute, rugose above, distinctly veined and whitish or ferruginous-tomentose beneath, 4–6 in. long: clusters dense; pedicels short; calyx minute; corolla campanulate, blood-red, pink, or white, usually spotted, 1– $1\frac{1}{2}$ in. across; ovary ferruginous-woolly or mealy, usually 7–9-celled. March–May. Himalayas. B.R. 890. P.M. 1:101. Gn. 64, p. 415. G.W. 6, p. 595. Var. *album*, DC. (*R. album*, Sweet, not Blume). Fls. white, spotted purple: lvs. ferruginous beneath. G. C. III. 29:246. Var. *cinnamomeum*, Lindl. Fls. white, slightly blushed, darker spotted than the preceding: lvs. cinnamon-brown beneath. B.R. 1982. Var. *limbatum*, Hook. Fls. with rosy limb and white throat, blotched purple at base: lvs. white beneath. B.M. 5311. Var. *Kingianum*, Hook. (*R. Kingianum*, Watt). Shrub: lvs. broader, strongly bullate, very dark: fls. deep scarlet; filaments rose-colored; calyx larger. G.C. III. 26:306. B.M. 7696. Var. *nilagiricum*, Clarke. Fls. rose-colored to deep crimson, spotted: lvs. ferruginous beneath. B.M. 4381. Gn. 36:54. Var. *puniceum*, DC. Fls. purple or scarlet: lvs. white beneath. Var. *Windsorii*, Voss (*R. Windsorii*, Nutt.). Fls. deep crimson-scarlet; calyx with elongated lobes: lvs. white beneath. B.M. 5008.—This species is tender and suited only for warmer temperate regions, but has been crossed with hardy varieties and its blood is recognizable in many of our most beautiful hardy hybrids.

18. *Smirnovii*, Trautv. Shrub or small tree, to 20 ft.: young branchlets whitish or grayish woolly: lvs. elliptic-oblong, acutish, narrowed at the base into a short petiole, revolute at the margin, dark green with yellow midrib above, densely felted grayish white or pale brown beneath, 3–5 in. long: fls. many, in a compact head; calyx small, tomentose; corolla campanulate-funnelform, rosy red, 3 in. across; lobes oval, longer than tube, with crisped darker rose-colored margin, upper lip spotted brownish; stamens 10, curved; ovary

tomentose. May. Caucasus. B.M. 7495. R.H. 1899: 500. G.C. III. 20:15; 49:417. Gt. 35:1226. G.W. 16, p. 147. M.D.G. 1909:356.

19. *caucasicum*, Pall. Dense low shrub, 2 ft. high, often with procumbent branches: lvs. oval-oblong or narrow-elliptic, acute, dark green above, ferrugineous-tomentose beneath, 2-4 in. long: clusters 7-10-fl.;

3384. *Rhododendron brachycarpum*. ($\times \frac{1}{4}$)

pedicels short; calyx minute; corolla funnelform-campanulate, with emarginate rounded lobes, pink to yellowish white, spotted greenish within, $1\frac{1}{2}$ in. across. June, July. Caucasus. B.M. 1145.—A dwarf, quite hardy species; late-flowering. Var. *flavidum*, Regel. Fls. straw-colored, spotted greenish within. Gt. 16:560. Var. *stramineum*, Hook., is similar, but with fulvous spots. B.M. 3422. Var. *roseo-album*, Briot., with bluish fls., changing to white, and var. *splendens*, Briot., with deep pink fls., are said to bloom very early and may be hybrids. R.H. 1868:311. Also "Coriaceum" and "Rosa mundi" (see p. 2932) are apparently forms of this species.

20. *Métternichii*, Sieb. & Zucc. (*R. Hymenánthes*, Makino. *R. japonicum*, Schneid., not Suring.). Shrub, 4 ft. high: lvs. oblong or oblong-lanceolate, narrowed at both ends, acute or obtuse, ferrugineous-tomentose beneath, 3-6 in. long: clusters 8-15-fl.; calyx minute; corolla campanulate, usually 7-lobed, rose-colored, spotted purple within, $1\frac{1}{2}$ -2 in. across; stamens usually 14. May, June. Japan. S.Z. 1:9. G. 32:91.—Like the preceding hardy, but rare in cult. Var. *pentamerum*, Maxim. Corolla 5-lobed; stamens 10 or 11. B.M. 8403. S.I.F. 2:60. Var. *angustifolium*, Bean. Lvs. narrower, to 7 in. long: fls. pale lilac-rose: of stiffly erect habit.

21. *brachycarpum*, Don. Fig. 3384. Shrub, 4 ft. high, sometimes 10 ft.: lvs. oval to oblong, rounded at both ends, mucronulate at the apex, bright green above, whitish or ferrugineous-tomentulose beneath, $2\frac{1}{2}$ -6 in. long: fls. in dense clusters, short-pedicelled; calyx-lobes short; corolla funnelform-campanulate, creamy white, spotted greenish within, $1\frac{1}{2}$ -2 in. across. June. Japan. G.F. 1:293 (adapted in Fig. 3384). B.M. 7881. G. 28:345.—Has proved quite hardy, but is still rare in cult.

22. *campanulatum*, Don. Shrub, attaining 16 ft.: lvs. elliptic to elliptic-oblong, usually rounded at both ends, ferrugineous-tomentose beneath, 3-6 in. long: clusters many-fl.; pedicels short; calyx-lobes short; corolla funnelform-campanulate, pale purple or pale lilac or almost white, with few purple spots, 2 in. across. June. Himalaya. B.M. 3759. L.B.C. 20:1944. Gn. 48, p. 108; 59, p. 294. G. 28:463. H.U. 1, p. 255.

—This is one of the hardiest of the Himalayan species. Var. *æuginodsum*, Nichols. (*R. æuginodsum*, Hook. f.). Lvs. with verdigris-colored tomentum beneath. Var. *Bâtemanii*, Nichols. (*R. Bâtemanii*, Hook.). Of more robust habit and with larger fls. B.M. 5387. Var. *Wállichii*, Hook. Lvs. with lax, often caducous tomentum, and with densely woolly petioles: corolla more highly colored. B.M. 4928.

23. *pónticum*, Linn. Shrub, 10 ft. high: lvs. elliptic to oblong, acute, pale green beneath, 3-5 in. long: clusters many-fl.; pedicels longer than fls., puberulous; calyx-lobes as long as ovary, the lower ones half as long; corolla funnelform-campanulate with oval lobes, purple, spotted brownish within, about 2 in. across; ovary glandular. May, June. Spain, Portugal, Asia Minor. B.M. 650.—This species is less hardy than the two preceding and now rarely found in cult. in its typical form. Var. *album*, Hort., has white fls. There are also varieties with variegated and one with purplish lvs.

24. *sutchuenense*, Franch. Shrub, to 15 ft.: lvs. oblong-ob lanceolate, usually obtuse, narrowed at the base, dark green above, paler and glabrous beneath, 4-10 in. long; petioles stout, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long: fls. many, in a dense head; pedicels glabrous; corolla funnelform-campanulate, 2- $2\frac{1}{2}$ in. across, rose-colored, spotted below the base of the upper lobes, lobes broad, rounded, shorter than tube; stamens 13-15, shorter than the corolla, anthers purple-black; style glabrous, as long as the stamens; ovary glabrous. W. China. B.M. 8362.—Blooms freely as a small plant 2 ft. high.

25. *californicum*, Hook. Shrub, 8 ft. high, sometimes to 20 ft., glabrous: lvs. oblong, shortly acuminate, pale green beneath, 3-6 in. long, sometimes crowded beneath the fls.: clusters many-fl.; calyx minute; corolla broadly campanulate, with oval crisped lobes, rosy purple or pink, paler toward the center, spotted yellow within, about 2 in. across, rich carmine in bud; stamens 10, with purple anthers; ovary with appressed silky hairs. May, June. Calif. to Brit. Col. B.M. 4863.—*R. macrophyllum*, Don, and *R. washingtonianum*, Hort., are probably not different.

26. *catawbiense*, Pursh. Figs. 3385, 3386. Shrub, 6 ft. high, rarely 20 ft.: lvs. rounded at base, oval to

3385. *Rhododendron catawbiense*. ($\times \frac{1}{4}$)

oblong, usually obtuse and mucronulate, glaucous beneath, 3-5 in. long: clusters many-fl.; pedicels rusty pubescent; corolla broadly campanulate, with broad roundish lobes, lilac-purple, about $1\frac{1}{2}$ in. across; ovary rusty tomentose. June. Va. to Ga., in the mountains. B.M. 1671. L.B.C. 12:1176. Gn.M. 2:18. F.E. 17:312 (pl. 71). M.D.G. 1902:381. G.W. 4, p. 97. G. 37:391.—One of the most beautiful of native shrubs, covering extensive tracts of land on the higher mountains of the

southern Alleghanies. Hardy as far north as New England.

27. *máximum*, Linn. GREAT LAUREL. Fig. 3387. Shrub, or small tree, attaining 35 ft.: lvs. mostly acute at base, narrow-oblong or lanceolate-oblong, acute or shortly acuminate; whitish beneath, 4–10 in. long; clusters many-fld.; pedicels viscid; calyx-lobes oval, as long as ovary; corolla campanulate, deeply 5-lobed with oval lobes, usually rose-colored, spotted greenish within, about 1½ in. across; ovary glandular. June, July. Nova Scotia and Ont. to Ga. B.M. 951. Em. 2:435. Mn. 1:1 and 3, p. 22. C.L.A. 3:32; 4:105. G.W. 15, p. 623.—This is one of the hardest species, being hardy as far north as Que. and Ont. Three varieties have been distinguished: var. *álbum*, Pursh (*R. Púrrshii*, Don), with white fls.; var. *purpúreum*, Pursh (*R. purpúreum*, Don), with purple fls., and var. *róseum*, Pursh, with pink fls. This species and the following are now often extensively used in park-planting and taken by the carloads from the woods. If properly handled and taken from a turfy soil with a sufficient ball of earth around the roots, they are usually successfully transplanted.

28. *azaleoides*, Desf. (*R. frágrans*, Lodd. *R. odorátum*, Paxt.). Hybrid between *R. mínus* and *R. nudiflorum*. Shrub, a few feet high: lvs. leathery but thin, elliptic to oblong, acute at both ends, dark green above, paler beneath, sometimes pubescent when young; fls. funnel-form-campanulate, pinkish or whitish, fragrant, 1½–2 in. across; calyx with ciliate lobes. May, June. P.M. 10:147. J.H. III. 49:489.—Of garden origin. There are many allied forms of similar origin described under different names. The name *Azaleodendron* has been proposed as a generic name for the hybrids between *Azalea* and *Rhododendron* by Rodigas. To this group of hybrids also belong *R. Smithii aureum*, Hort., with yellow fls. F.S.R. 2:152, and *R. Broughtonii aureum*, Hort., similar, but with deeper yellow fls. and with the under side of the lvs. green, not glaucescent as in the preceding form (G.C. III. 51:53); also *R. Cartoniánum*, DC., *R. gemmiferum*, Bean, and *R. Góweniánum*, Sweet (see suppl. list).

3387. *Rhododendron maximum*. (×¼)

Subgenus II. AZALEA.

Section 3. AZALEASTRUM.

29. *albiflorum*, Hook. (*Azalea albiflora*, Kuntze. *Azaleastrum albiflorum*, Rydb.). About 2–3 ft.: branches strigose and glandular when young; lvs. oblong, pale green, appressed-strigose above and at the midrib beneath, slightly ciliate; fls. nodding, on short pedicels; corolla white, 5-cleft, about 1 in. broad; calyx glandular; stamens 10. Rocky Mts. B.M. 3670. Var. *plénium*, Rehd. A very handsome double form

found wild, but not yet in cult.—The species is hardy, but difficult to cult.; will probably succeed best on a rocky in a cool and shady place.

3386. Flower-bud of *Rhododendron catawbiense*. These buds are full-formed in the fall. Unless these large terminal buds are produced, the bush will not bloom the following spring. (×½)

Section 4. PENTANTHERA.

- A. Stamens longer than the limb; corollatube long and narrow, usually glandular outside.
- B. Color of fls. white or pink.
- C. Fls. with or after the lvs., white.
- D. Corolla soft-pubescent outside, with yellow stripes on the upper lobe; branchlets glabrous or finely pubescent..... 30. *occidentale*
- DD. Corolla hirsute, with stalked glands.
- E. Lvs. beneath and branchlets glabrous..... 31. *arborescens*
- EE. Lvs. strigose beneath on the midrib and branchlets strigose..... 32. *viscosum*
- CC. Fls. before the lvs., pink, rarely whitish.
- D. Lvs. strigose beneath: corolla usually not glandular..... 33. *nudiflorum*
- DD. Lvs. grayish soft-pubescent beneath: corolla glandular outside..... 34. *canescens*
- BB. Color of fls. yellow to flame-red.
- C. Ovary not glandular; stamens much longer than corolla: lvs. generally obovate..... 35. *calendula-ceum*
- CC. Ovary glandular; stamens little longer than corolla: lvs. generally oblong..... 36. *luteum*
- AA. Stamens shorter than the limb; corollatube short, funnel-form, finely pubescent outside, not glandular.
- B. Under side of lvs. soft-pubescent: corolla yellow..... 37. *sinense*
- BB. Under side of lvs. only strigose on the veins: corolla brick-red to carmine. 38. *japonicum*

30. *occidentale*, Gray (*Azalea occidentalis*, Torr. & Gray. *A. californica*, Durand). Shrub, 2–6 ft.: branchlets glabrous or pubescent; lvs. obovate-oblong, finely ciliate, slightly pubescent beneath when young, 1–2 in. long; corolla 2–2½ in. long, white or slightly tinged rose, with yellow on the upper lobe, fragrant. May, June. Calif. B.M. 5005. F.S. 14:1432. Gn. 34:416. G.W. 11, p. 8; 15, p. 650.

31. *arboréscens*, Torr. (*Azalea arboréscens*, Pursh). SMOOTH AZALEA. Fig. 3388. From 8–20 ft.: branchlets glabrous: lvs. obovate or obovate-oblong, acute, ciliate, glabrous, green or glaucescent beneath, 2–4 in. long: fls. white or tinged rose, 2 in. long, fragrant; style and stamens red. June, July. Alleghany Mts. G.F. 1:401 (adapted in Fig. 3388). C.L.A. 11:496. Gn.M. 5:219. L.B.C. 17:1632 (as *A. verticillata*).

32. *viscōsum*, Torr. (*Azalea viscōsa*, Linn.). WHITE SWAMP HONEYSUCKLE. From 4–8 ft.: winter buds glabrous: branchlets with stiff hairs: lvs. obovate-oblong, obtuse or mucronulate, ciliate, bristly hairy on the veins beneath, 2–4 in. long: fls. white or tinged rose, 1½–2 in. long, viscid outside, fragrant; style red. June, July. E. N. Amer. Em. 2:438. Mn. 10:81. C.L.A. 11:496. Var. *nitidum*, Gray. From 1–3 ft.: lvs.

3388. *Rhododendron arborescens*. (×¼)

oblongate, bright green on both sides: corolla tinged red. B.R. 414. Var. *gladum*, Gray. Lvs. whitish-glaucous beneath, dull and glaucous above. L.B.C. 16:1518. Var. *hispidum*, Schneid. (*Azalea hispida*, Pursh). Pedicels bristly hispid: fls. usually pink: lvs. glaucescent beneath. L.B.C. 5:441.

33. *nudiflorum*, Torr. (*Azalea lutea*, Linn., partly. *A. nudiflora*, Linn.). PINKSTER FLOWER. Figs. 3389, 3390. Height 2–6 ft.: winter buds more or less pubescent: branchlets pubescent and often with stiff hairs: lvs. oblong or obovate, strigose on the midrib beneath, 2–4 in. long: fls. pink to nearly white, before the lvs., about 1½ in. broad, strigose or slightly glandular outside, faintly fragrant; pedicels strigose-hairy. April, May. Mass. to Fla. and Texas. B.R. 120. L.B.C. 1:51. Mn. 2:17. Gn. 29, p. 550.

34. *canéscens*, Don (*Azalea canéscens*, Michx.). Shrub, 1–3 ft.: similar to the preceding: lvs. oval to elliptic or obovate, soft-pubescent beneath, at least when young, 1½–3 in. long: pedicels glandular: fls. pink to nearly white, 1½–2 in. broad, glandular outside, very fragrant; stamens slightly exserted. April, May. N.H. to Fla. and La.

35. *calendulaceum*, Torr. (*R. luteum*, Schneid., not Sweet. *Azalea calendulacea*, Michx. *A. lutea*, Linn., partly. *A. aurantiaca*, Dietr. *A. speciosa*, Willd.). FLAME-COLORED AZALEA. From 4–10 ft.: branchlets glabrous or with stiff hairs: lvs. obovate or ovate, usually pubescent beneath, serrulate-ciliate: fls. orange-yellow to orange-red or flame-red, often 2 in. broad, with the lvs., nearly scentless; tube usually shorter than the limb; stamens thickened at the middle. May,

June. E. N. Amer. C.L.A. 11:496. Gn. 29, p. 550. B.R. 145. L.B.C. 7:624. B.M. 180. Var. *crōceum*, Rehd. Fls. yellow or orange-yellow. B.M. 1721. L.B.C. 14:1324.—One of the most showy species.

36. *luteum*, Sweet (*R. flavum*, Don. *Azalea pōntica*, Linn.). Shrub, 2–6 ft.: branchlets hairy: pedicels and petioles glandular: lvs. cuneate, oblong, usually hairy on both sides when young, 2–4 in. long: fls. yellow, 2–2½ in. broad, very fragrant; stamens as long as the limb. May. Orient, Caucasus. B.M. 433; 2383 (var. *albiflora*). C.L.A. 11:495. G. 27:15. Gn. 29, p. 550. G.M. 36: 500.—A very fragrant and free-flowering species, not common in cult. Nearly all varieties referred to this species in nursery catalogues are hybrids and belong to the so-called Ghent azaleas, *R. Morteri*, Sweet (*Azalea Mortieriana*, Spae. *A. gandavensis*, Hort.); see p. 2935.

3389. *Rhododendron nudiflorum*. (×¼)

37. *sinéense*, Sweet (*R. mōlle*, Don. *Azalea sinénsis*, Lodd. *A. mōllis*, Blume). Shrub, to 5 ft.: young branchlets pubescent and often setose: winter buds grayish pubescent: lvs. oblong to oblong-oblanccolate, obtuse and mucronate, cuneate at the base, ciliate and often revolute at the margins, soft-pubescent beneath, 2½–3½ in. long: fls. in many-fld. heads; pedicels puberulous; calyx-lobes short, rounded, ciliate; corolla campanulate-funnelform, yellow, upper lobe spotted greenish, 2 in. across; stamens shorter than limb. April, May. China. B.R. 1253. L.B.C. 9:885.—Tenderer than the following species with which it has been confused. It has entered largely into the parentage of the so-called Ghent azaleas, and some of them, particularly Anthony Koster, are little different from true *R. sinense*.

38. *japōnicum*, Suring. (*R. mōlle*, Miq., not Don. *Azalea japōnica*, Gray. *A. mōllis*, Hort., not Blume). Fig. 3392. Shrub, to 6 ft.: young branchlets glabrous, sometimes setose: winter buds glabrous: lvs. obovate to obovate-oblong, obtuse and mucronate, cuneate at the base, ciliate, glabrous or sparingly setose above, glabrous below except setose on the midrib, 1½–3 in. long: fls. in dense heads; pedicels setose; calyx-lobes ovate, setose; corolla campanulate-funnelform, 2 in. across, salmon-red, brick-red, or carmine; stamens shorter than limb. April, May. Japan. F.S. 19:2032–6. Gn. 29, p. 551; 33, p. 324; 42, p. 369; 46, p. 546; 59:403. Gn.M. 4:24. C.L.A. 4:210; 5:147; 11:495. Gt. 16:556; 57:1575. M.D.G. 1906:556. G. 2:503; 5:219. Gng. 4:279. S.I.F. 2:62.—This and the preceding species have been hybridized extensively with *R. luteum* and the American azaleas and almost all the varieties now in trade under the names of these two species are hybrids. The type of *R. japonicum* has been reintro. from Japan by C. S. Sargent and that of *R. sinense* from China by E. H. Wilson, and they have been distributed by the Arnold Arboretum. *R. japonicum* is hardy at the Arnold Arboretum; *R. sinense* is tenderer, but stands ordinary winters in favorable positions.

3390. Capsule of *Rhododendron nudiflorum*.

Section 5. RHODORA.

- A. Stamens 10; corolla rosy purple, not spotted.....39. *canadense*
 AA. Stamens 7 or 5; corolla pale rose-colored, spotted.....40. *Vaseyi*

39. *canadense*, Zabel (*R. Rhodora*, Don. *Rhodora canadensis*, Linn. *Azalea canadensis*, Kuntze). Shrub,

1-3 ft.: lvs. oval to oblong, obtuse and mucronulate, glaucous and slightly pubescent beneath, 1-2½ in. long; fls. 5-7, on very short pedicels, before the lvs.; corolla 2-lipped, the two lower segms. narrow, divided nearly to the base, rose-purple, not spotted, 1-1½ in. broad; stamens 10. April, May. Newfoundland to Que., south to Pa. and N. J. Em. 2:441. B. M. 474. C.L.A. 11:496. Gn.M. 5:221. G.W. 9, p. 474; 14, p. 85. M.D.G. 1902:286; 1906:73.

3391. *Rhododendron Vaseyi*. (×¾)

40. *Vaseyi*, Gray (*Azalea Vaseyi*, Rehd. *Biltia Vaseyi*, Small). Fig. 3391. From 5-15 ft. high: branchlets without bristles: lvs. oblong or oblong-lanceolate, acute, sparsely hirsute, 2-5 in. long; fls. before the lvs.; corolla rotate-campanulate, slightly 2-lipped, divided to below the middle, pale rose-colored, 1½ in. across, upper lobes spotted, lower lobes widely spreading, divided nearly to the base; stamens 7, rarely 5. April, May. N. C. G.F. 1:377 (adapted in Fig. 3391). G.C. III. 20:71; 51:313. B.M. 8081. Gn. 76, p. 332; 79, p. 302. Mn. 7:121. C.L.A. 11:499. Gn.M. 5:219. M.D.G. 1899:332, 333. G.W. 16, p. 231.—A very handsome, hardy species. There is also a form with white fls., var. *album*, Rehd., but this is not quite so beautiful as the type.

Section 6. TSUTSUTSI (Tsusia).

- A. Corolla rotate-campanulate, divided to below the middle: lvs. deciduous.
 B. Lvs. rhombic-ovate, acute: corolla not spotted.....41. *rhombicum*
 BB. Lvs. obovate, obtuse: upper lobes of corolla spotted.....42. *Schlippenbachii*
 AA. Corolla funnelform-campanulate: lvs. deciduous or persistent.
 B. Inner bud-scales viscid when unfolding.
 C. Sepals obtuse, ciliate, not glandular.....43. *poukhanense*
 CC. Sepals acute, lanceolate, glandular-ciliate.....44. *ledifolium*
 BB. Inner bud-scales not viscid.
 C. Fls. solitary, 2-3 in. across; anthers purple; sepals small, ovate: lvs. persistent, lustrous above.....45. *indicum*
 CC. Fls. 2-3, smaller: lvs. subsistent or deciduous, dull.
 D. Stamens 7-10, anthers purple; sepals ovate to lanceolate: lvs. elliptic, acute, subsistent, 1-2 in. long.....46. *Simsii*
 DD. Stamens 5; anthers usually yellow.

- B. Lvs. deciduous, elliptic, acute. 1-2½ in. long; fls. 1½-2 in. across, anthers yellow. 47. *Kaempferi*
 EE. Lvs. subsistent, obovate to elliptic, obtuse or acutish, ½-1½ in. long; fls. ½-1½ in. across; anthers sometimes purple.....48. *obtusum*

41. *rhombicum*, Miq. (*Azalea rhombica*, Kuntze). Shrub, 3-8 ft.: lvs. rhombic-ovate to rhombic-elliptic, acute at both ends and sparsely hairy above, yellowish pubescent at the nerves beneath, 1½-2½ in. long; fls. 2-3; corolla 1½-2 in. broad, rotate-campanulate, bright rose-colored, segms. oblong, not spotted; stamens 10. April, May. Japan. B.M. 6872. Gt. 17:586. G.C. III. 20:38. Gn. 72, p. 267. R.H. 1909, p. 79. Var. *albiflorum*, Makino. Fls. white.

42. *Schlippenbachii*, Maxim. (*Azalea Schlippenbachii*, Kuntze). Three to 5 ft.: branchlets glandular-pilose: lvs. cuneate, broadly obovate, 2-5 in. long, rounded and mucronate at the apex, hirsute on both sides or glabrous at length: fls. with the lvs., 2-3 in. broad, pale rose-colored, upper lobes spotted reddish brown; stamens 10. May. Japan. B.M. 7373. Gn. 46:80; 77, p. 136. G.C. III. 19:561; 55, suppl. Jan. 3.

43. *poukhanense*, Léveillé (*R. coreanum*, Rehd.). Spreading shrub, 1-3 ft.: lvs. chartaceous, subsistent, narrow-elliptic to elliptic-lanceolate, or lanceolate at the end of the branchlets, dark green above and usually sparingly strigose, paler beneath and strigose on the veins, 1¼-2½ in. long; fls. 1-3; the inner scales of the bud viscid; sepals ¼-½ in. long, ovate-oblong, obtuse, strigose and long-ciliate; corolla funnelform-campanulate, pale lilac-purple, spotted purplish brown on the upper lobes, about 2 in. across; stamens 10, anthers purple. May. Korea.—Has proved perfectly hardy at the Arnold Arboretum and flowers freely as a small plant; the purple-lilac color of the fls. is unique among hardy azaleas. Var. *yodogawa*, Rehd. (*Azalea yodogawa*, Hort.). Fls. double, rosy lilac, spotted dark purple: lvs. elliptic-lanceolate. G.W. 16:163. R.H. 1908:425.

44. *ledifolium*, Don (*R. rosmarinifolium*, Dipp.,

not Vidal. *Azalea rosmarinifolia*, Burm. *A. alba*, Sweet. *A. ledifolia*, Hook. *A. liliiflora*, Poit.). Much-branched low shrub, 1-3 ft.: branches, lvs. and pedicels densely rufously appressed - strigose: lvs. elliptic or elliptic-lanceolate, persistent, 1-3 in. long; fls. 1-3; sepals lanceolate, serrate - glandular; corolla pure white or rosy purple, 2-3 in. broad, fragrant; stamens usually 10. May. China. B.R. 811. B.M. 2901. L. B. C. 13:1253. G. 28:323. Gn. 33, p. 321. G.W. 15, p. 650.—Some remarkable varie-

3392. *Rhododendron japonicum* (×¾)

ties of this species are the following: Var. *album*, Rehd. (*R. ledifolium* var. *leucanthum*, DC. *A. indica* var. *alba*, Lindl. *R. leucanthum*, Bunge). Fls. white, sometimes striped pink. G.C. III. 33:373. Gn. 54, p. 487. G. 6:607. Var. *Noordtiandum*, Rehd. (*Azalea ledifolia* *Noordtianda*, Wittm. *A. japonica alba grandiflora* Van Noordt, Hort.). Fls. white, larger; lvs. elliptic. R.B. 30:133. M.D.G. 1905:73, 74. Gt. 59, p. 310. G.W. 15, p. 45. Said to be the hardest variety of this species. Var. *purpureum*, Maxim. Fls. rosy purple. Var. *narcissiflorum*, Maxim. (*A. narcissiflora*, Fort.). Fls. double, white, rarely purple. F. 1880:89. Var. *phoeniceum*, DC. (*A. punicea*, Sweet. *A. ledifolia* var. *phoenicea*, Hook. *A. indica* var. *calycina*, Paxt.). Fls. single, purple; calyx with linear, not serrate and less glandular lobes. B.M. 3239. L.B.C. 18:1735. J.F. 3:257. Possibly a hybrid of this species and *R. sublancoletum*.—*R. ledifolium* has produced, with *A. indica*, a large number of beautiful hybrids, of which one of the first was figured in 1833 as *R. pulchrum*.

45. *indicum*, Sweet (*R. macranthum*, Don. *R. Danielsianum*, Planch. *Azalea indica*, Linn. *A. macrantha*, Bunge. *A. Danielsiana*, Paxt.). Low much-branched shrub: lvs. evergreen, elliptic to lanceolate-oblong, obtuse or acute, dark green and lustrous above, paler and slightly strigose below, 1-2 in. long; fls. usually solitary; sepals small, ovate, ciliate; corolla funnel-form, 2-3 in. across, rosy purple to pink; stamens 5-10, anthers purple. June, July. Japan. P.M. 1:129. Var. *crispiflorum*, Schneid. (*Azalea crispiflora*, Hook.). Fls. large, rose-colored, with distinctly crisped segms. B.M. 4726. F.S. 9:887. Var. *lateritium*, Rehd. (*Azalea indica* var. *lateritia*, Lindl.). Fls. salmon- or brick-red; lvs. oblong-lanceolate. B.R. 1700. Var. *rosiflorum*, Rehd. (*Azalea rosiflora*, Flor. Mag. *A. balsaminiflora*, Carr. *A. Rollissonii*, Hort.). Lvs. oblong-lanceolate: fls. salmon-red, very double, with imbricated oblong segms., resembling the fl. of a camellia-fl. balsam. F.M. 19:418. Gn. 18:254. R.H. 1882:432. F. 1878, p. 35. G.Z. 29, p. 265.—This species is the origin of most of the beautiful garden forms of Indian azaleas raised by hybridizing with the allied species, particularly *R. Simsii* and *R. ledifolium*; many of the forms were intro. from Chinese and Japanese gardens. Gn. 33, p. 139; 50, p. 192; 54, p. 487; 73, p. 202. G.C. III. 24:101. R.B. 20:121; 23:37; 25:73. A.G. 14:473. Gng. 4:359. F.E. 9:431. F.R. 2:579. C.L.A. 7:479. Gn.M. 5:220.

46. *Simsii*, Planch. (*R. indicum* var. *Simsii*, Maxim. *R. indicum* var. *ignescens*, Sweet. *Azalea indica*, Sims, not Linn.). Half-evergreen or evergreen shrub, to 10 ft.: lvs. elliptic-ovate to elliptic-lanceolate, rarely lan-

ceolate, acute, cuneate at base, sparingly strigose and dull above, more densely so beneath, at least on the veins, $\frac{3}{4}$ -2 in. long; fls. 2-3, sepals ovate to lanceolate, densely strigose and ciliate; corolla funnel-form, $1\frac{1}{2}$ -2 in. across, carmine or rose-colored; stamens 7-10; anthers purple. May, June. W. China. B.M. 1480. L.B.C. 3:275.—The typical form has been recently re-intro. by E. H. Wilson.

47. *Kaempferi*, Planch. (*R. indicum* var. *Kaempferi*, Maxim.). Fig. 3393. Shrub, to 12 ft.: lvs. membranous, deciduous, broadly elliptic to elliptic-ovate or nearly rhombic, acute at the ends, bright green above, paler beneath, strigose on both sides, with rufous hairs on midrib and petiole, $1\frac{1}{4}$ -2 $\frac{1}{2}$ in. long; fls. 2-4 with or before the lvs.; sepals oval to oblong-ovate, obtuse, long-ciliate, strigose outside; corolla broadly funnel-form, $1\frac{1}{2}$ -2 in. across, bright orange-red to pink; stamens 5; anthers yellow. April, May. Japan. S.I.F. 2:61. C.L.A. 11:496. M.D.G. 1902:417. S.T.S. 2:113.—Very handsome; hardy in New England.

48. *obtusum*, Planch. (*R. indicum* var. *obtusum*, Maxim. *Azalea obtusa*, Lindl.). Low, much-branched shrub: lvs. persistent, obovate, rounded and mucronulate at the apex, dark green and lustrous above, strigose on the midrib beneath, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long; fls. 2-3; sepals ovate, small, ciliate; corolla funnel-form, orange-red or pink, 1-1 $\frac{1}{2}$ in. across; stamens 5; anthers yellow. May. Japan. B.R. 32:37. G.C. II. 25:585. R.H. 1876:370. Gn. 67, p. 190. Var. *album*, Schneid. (*Azalea obtusa alba*, Hort.). Fls. white. G.F. 9:395. Var. *calyciflorum*, Schneid. (*Azalea calyciflora*, Hort.). Fls. brick-red, corolla double (hose-in-hose). Var. *amœnum*, Rehd. (*R. amœnum*, Planch. *Azalea amœna*, Lindl.). Lvs. elliptic or elliptic-obovate, acute or obtusish, $\frac{1}{2}$ -1 in. long, dark green; corolla usually double (hose-in-hose), purple, $\frac{1}{2}$ -1 in. broad; stamens 5; anthers often purple. April, May. B.M. 4728. F.S. 9:885. G.C. III. 23: fig. 125. A.G. 15:373; 18:568. Gng. 2:385; 11:289. A.F. 12:33; 20:751. F.E. 9:573. J.F. 4:329. This variety, of which the wild parent plant is unknown, seems to have some relations to *R. Simsii* and may be of hybrid origin. It flowers early and very abundantly; hardy north to N. Y. There are some forms and crosses of this variety of which the following may be named: *album*, with white fls. M.D.G. 1903:476; *Caldwellii*, with larger purple fls. (Geert, Ic. Az. 18); G. 32:21; *Marvel*, lilac-carmine, double (F.M. 11: 14); *Princess Maud*, rosy magenta (R.H. 1886:516); *Mrs. Carmichael*, crimson-magenta; *Princess Beatrice*, bright mauve; *Prime Minister*, soft pink; *Miss Buist*, pure white; *Heze* (Firefly), deep crimson. In Japanese gardens a large number of named varieties of *R. obtusum*, varying in shades from white to deep crimson, are grown; one of the best known of them is *Hinodigiri*, with brilliant crimson fls.

Great numbers of names of rhododendrons are to be found in current literature, but the plants may be unknown in the American trade. The following list will explain most of these names. The number in parenthesis after the name refers to the section to which the species belongs. *R. adenopodum*, Franch. (2). Shrub, to 10 ft.: lvs. oblong-lanceolate, with white crustaceous tomentum beneath, 3-6 in. long; fls. 4-6, campanulate, pale rose, $2\frac{1}{4}$ -3 in. across; pedicels glandular. Cent. China. G.C. III. 45:291.—*R. affghanicum*, Hort., not Aitch.—*R. Collettianum*,—*R. Albrechtii*, Maxim. (*Azalea Albrechtii*, Kuntze) (5). Deciduous shrub, to 5 ft.: lvs. obovate or elliptic, pubescent, 3-5 in. long; fls. purple; stamens 10. Japan.—*R. album*, Blume (1). Small shrub: lvs. oblong-lanceolate, ferruginous-lepidote beneath, 3-4 in. long; fls. rather small, campanulate, yellowish white. Java. B.M. 4972. Tender.—*R. alacraense*, Lindl. Hybrid of *R. arboreum* with *R. catawbiense* × *R. ponticum*. Fls. bright crimson, in dense heads. B.R. 1414. B.M. 3423. Not to be confounded with *Azalea alacraensis*, Lindl. (*R. sinense* × *R. viscosum*. B.R. 28:27).—*R. ambiguum*, Hemsl. (1). Shrub, to 10 ft.: lvs. lanceolate, glabrous above, sparingly lepidote beneath, 2-3 in. long; fls. 5-7, broadly campanulate, yellow, 2 in. across. W. China. B.M. 8400.—*R. Amesiae*, Rehd. & Wilson (1). Allied to *R. yanthinum*. Shrub, to 10 ft.: lvs. elliptic to elliptic-oblong, rounded at base, lepidote, villous on the midrib above, 2-3 in. long; petioles setose; fls. 2-3, funnel-form, $1\frac{1}{4}$ -2 in. across, purple. W. China.—*R. Annez*, Franch. Lvs. lanceolate, coriaceous; fls. white, medium-sized; corolla flat and disk-like. W. China.—*R. Antiochogon*, D. Don. Low shrub: lvs. elliptic-oblong, ferruginous-

3393. *Rhododendron Kaempferi*. (× $\frac{1}{2}$)

lepidote beneath, $1\frac{1}{2}$ in. long; fls. small, funnelform, yellowish white, $\frac{1}{4}$ in. long; stamens 5, included. Himalayas. B.M. 3947. Almost hardy.—*R. argenteum*, Hook. f.—*R. grande*.—*R. argyrophylum*, Franch. (2). Shrub, to 15 ft.: lvs. oblong-lanceolate or oblanceolate, with white crustaceous tomentum beneath, 3–6 in. long; fls. 7–10, slender-stalked, funnelform-campanulate, $1\frac{1}{2}$ in. across, pale rosy-purple; stamens 14, included. W. China. Very variable.—*R. Aucklandii*, Hook. f.—*R. Griffithianum* var. *Aucklandii*.—*R. auriculatum*, Hemsl. (2). Shrub, to 15 ft.: lvs. oblong, obtuse and mucronate, auriculate at the base, rusty-tomentose beneath, 4–8 in. long; fls. 6–8, white to rosy red, funnelform, about 3 in. across; pedicels hairy; bud-scales lanceolate. Cent. China. J.H.S. 28, p. 64.—*R. balsaminiflorum*, Hort. Hybrid of the Javanese group, with double pink fls. G.C. II. 18:230; III. 12:769. Gt. 37, p. 265. G.Z. 27:241. J.H. III. 43:151. Var. *album*, Hort. Fls. double, white. Gn.W. 5:373. G.Z. 27:241. Var. *aureum*, Hort. Fls. double, yellow. G.Z. 27:241. The name has also been used for a double form of *R. indicum*, see *R. indicum* var. *rosiflorum*.—*R. barbatum*, Wall. (2). Tree, attaining 60 ft.: lvs. with setose petioles, elliptic-oblongate, glabrous and pale beneath, 5–7 in. long; fls. deep red, campanulate, $1\frac{1}{2}$ in. across, in dense clusters. Himalayas. F.S. 5:469–72. G.M. 53:261. Var. *Smithii*, Clarke. Lvs. ferrugineously subtomentose beneath. B.M. 5120.—*R. blandfordii*, Hook. (1). Slender shrub, 8 ft. high, allied to *R. cinnabarinum*: lvs. oblong-lanceolate, ferrugineous-lepidote beneath, 2–3 in. long; fls. funnelform, with cylindric tube, brick-orange-red, yellow within, $2\frac{1}{2}$ in. long. Himalayas. B.M. 4930. F.S. 11:1173. I.H. 3:112. B.H. 7, p. 47. G.C. 1856:548; 1871:236. Gn. 15:182 (as *R. cinnabarinum*).—*R. Boddii*, Nutt. (1). Shrub, 6 ft. high, often epiphytal: lvs. ovate-oblong, or oblong-lanceolate, hirsute above when young, minutely lepidote beneath, 4–5 in. long; fls. in dense clusters, campanulate, yellow, $1\frac{1}{2}$ in. across. Himalayas. B.M. 7149. I.H. 5:174.—*R. bracteatum*, Rehd. & Wilson (1). Allied to *R. yanthinum*. Shrub, to 6 ft.: lvs. oblong, obtuse, lepidote beneath, 1–2 in. long, toward the base of the branchlets reduced to persistent bracts: fls. 3–6, white, spotted red, broadly campanulate, $1\frac{1}{2}$ in. across. W. China.—*R. Bréti*, Hemsl. & Wilson.—*R. longesquamatum*.—*R. Brookendunum*, Low (1). Shrub, often epiphytal, with glabrous purple branches: lvs. oblong-lanceolate, pale beneath, 6–9 in. long; fls. funnelform-campanulate, orange- or golden-yellow, $2\frac{1}{2}$ in. across. Borneo. B.M. 4935. F.S. 5, p. 477; 12:1238, 1239. G.C. III. 9:621. Var. *flavum*, Hort. Fls. paler yellow. G.Z. 23, p. 145.—*R. Broughtonii*, Hort. One of the hybrid ever-green rhododendrons of unknown parentage with bright rosy red fls.—*R. Broughtonii aureum*, Hort. See under No. 28, *R. azaleoides*.—*R. bullatum*, Franch. (2). Shrub, to 5 ft.: branchlets woolly: lvs. elliptic-oblong or oblong-ovate, dull green and wrinkled above, with brownish tomentum beneath, 2–3 in. long; fls. 3–6, white with yellow blotch, broadly campanulate, 2 in. across, fragrant; calyx large. G.C. III. 46:378. S.W. China.—*R. burmanicum*, Hutchins. (1). Lvs. oblanceolate, densely scaly on both sides, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long; fls. greenish white, very sweet-scented. Burma.—*R. calophyllum*, Nutt. (1). Shrub, 3 ft. high: lvs. oblong-ovate or elliptic, glossy above, lepidote beneath, 3–5 in. long; fls. 4–5, tubular-campanulate, white, slightly tinged yellowish green, 3 in. across. Himalayas. B.M. 5002. F.S. 22:2340.—*R. calophyllum*, Franch. (2). Shrub or small tree, to 45 ft.: lvs. oblong-obovate, glabrous, 8–12 in. long; fls. 15–20, long-stalked, purple, rose-colored or white, broadly campanulate, 2 in. across; stamens about 20; ovary glabrous. W. China.—*R. camelliaeflorum*, Hook. f. (1). Shrub, 6 ft. high, often epiphytal: lvs. elliptic-lanceolate, ferrugineous-lepidote beneath, 2–3 in. long; fls. 1–2, short-pedicelled, broadly campanulate, white or slightly tinged rose, $1\frac{1}{2}$ in. across; stamens 16. Himalayas. B.M. 4932.—*R. campylocarpum*, Hook. f. (2). Shrub, 6 ft. high: lvs. elliptic, obtuse, mucronulate, glabrous and glaucous beneath, 2– $3\frac{1}{2}$ in. long; fls. several, campanulate, yellow, fragrant, to $2\frac{1}{2}$ in. across. Himalayas. B.M. 4968. Gn. 54:182; 78, p. 573. G.C. II. 21:833; III. 11:501 and 12:699. G. 25:195; 28:379; 36:379; 37:19. G.M. 57:851.—*R. candidum*, Rehd. (*Azalea candida*, Small) (4). Allied to *R. viscosum*. Shrub, to 6 ft.: lvs. oblong or obovate-oblong, thinly tomentose above, densely white-tomentose and reticulate beneath, $\frac{1}{2}$ –2 in. long; fls. white or pinkish, 1 in. across, after the lvs. Ga.—*R. carneum*, Hutchins. (1). Allied to *R. Veitchianum*. Shrub, to 3 ft.: lvs. elliptic-obovate, glabrous, glaucous and scaly beneath, $2\frac{1}{4}$ – $4\frac{1}{2}$ in. long; fls. campanulate-funnelform, flesh-colored, $3\frac{1}{2}$ in. across; stamens usually 12. Burma. B.M. 8634.—*R. Cartonianum*, DC. (*R. Cartoni*, Hort.). Allied to *R. azaleoides* and said to be of the same parentage as *R. Gowenianum*, but lvs. glabrous and fls. more violet, whitish toward the base. B.R. 1449.—*R. Cavenii*, André. Hybrid of *R. formosum* and *R. Veitchii*. Lvs. elliptic: fls. white, usually slightly tinged rose, fragrant, $3\frac{1}{2}$ in. across. R.H. 1885:60.—*R. Championae*, Hook. f. (*Azalea Championae*, Kuntze) (6). Shrub, to 6 ft.: lvs. oblong-lanceolate, acuminate, dark green and glabrous above, rusty colored and pilose beneath, ciliate, $2\frac{1}{2}$ –6 in. long; fls. 4–6, wide campanulate-funnelform, with oblong lobes, 3 in. across, rose-colored; stamens 10. Hong-Kong. B.M. 4609. J.F. 2:208.—*R. chartophyllum*, Franch. (1). Allied to *R. racemosum*. Shrub, to 3 ft.: lvs. elliptic, acuminate, lepidote beneath, $2\frac{1}{2}$ – $3\frac{1}{2}$ in. long; fls. 6–12, light pink, spotted, funnelform-campanulate, 2 in. across. S.W. China. G.C. III. 51:291. Gn. 78, p. 304. R.H. 1912, p. 135.—*R. chrysanthum*, Pall. Low shrub, 2 ft. high: lvs. elliptic-oblong, acute, 1–2 in. long, ferrugineous beneath: fls. few, slender-pedicelled, broadly campanulate, yellow, $1\frac{1}{2}$ in. across. Siberia, Kamchatka. Hardy.—*R. ciliatum*, Hook. f. (1). Small shrub, 2–4 ft.: lvs. elliptic, acuminate, pilose above, ciliate, pale and lepidote beneath, 2 in. long; fls. several, campanulate, pale purple, $1\frac{1}{2}$ in. across. Himalayas. G.C. III. 29:247. Gn. 59, p. 351; 67, p. 266; 75:202. G. 36:658. Var. *roseo-album*, Hook. Fls. larger, white, tinged rose. B.M. 4648. F.S. 8:766. Gt. 16:563. J.F. 3:312.—*R. cilioliz*, Franch. (1). Small shrub: lvs. elliptic-obovate, shortly

acuminate, ciliate, pale and lepidote beneath: fls. 7–10, campanulate, white, 2 in. across. Yunnan. R.H. 1899:36. B.M. 7782. G.W. 8, p. 245.—*R. cinnabarinum*, Hook. f. (1). Slender-branched shrub: lvs. elliptic to elliptic-lanceolate, lepidote beneath, 2–3 in. long; fls. many, nodding, tubular-campanulate, rose-orange or brick-red, $1\frac{1}{2}$ in. long. Himalayas. G. 34:111. Var. *pidium*, Hook. Lvs. glaucous beneath: fls. pale rose, spotted red within. B.M. 4788. Var. *Roylei*, Hook. Lvs. ferrugineous beneath: fls. larger, of brighter color. Gn. 44:558. G.C. II. 21:765; III. 12:709.—*R. citrinum*, Hassk. Small shrub: lvs. elliptic-oblong, obtuse, lepidote and pale beneath, $1\frac{1}{2}$ –2 in. long; fls. several, nodding, campanulate, pale yellow, $\frac{1}{4}$ in. long, fragrant. Java. B.M. 4797. Tender.—*R. divianum*, Hook. Hybrid of *R. arboreum* album and *R. catawbiense*. Fls. white, blushed and spotted carmine. B.M. 4478.—*R. Collettianum*, Aitch. & Hemsl. Shrub, 10 ft. high: lvs. elliptic-lanceolate, brownish lepidote beneath, $1\frac{1}{2}$ –3 in. long; fls. short-pedicelled, funnelform, white, 1 in. long. Afghanistan. B.M. 7019. G.C. III. 4:297. J.H. III. 51:502.—*R. concinnum*, Hemsl. (*R. coombense*, Hemsl.) (1). Shrub, to 10 ft.: lvs. oval, lepidote beneath, 1–2 in. long; fls. 3–5, purple, campanulate, $1\frac{1}{2}$ in. across. W. China. B.M. 8280, 8620. G.C. III. 53:341.—*R. coombense*, Hemsl.—*R. concinnum*.—*R. crasnum*, Franch. Closely allied to *R. Maddenii*, differing in its larger calyx-lobes. S. W. China.—*R. Cunninghamii*, Moore. Hybrid of *R. arboreum* var. *cinnamomeum* and *R. maximum* var. *album*. Fls. white, spotted purple. Moore, Gard. Mag. Bot. 1851:121. Not to be confounded with *R. Cunninghamii* White, a variety or hybrid of *R. caucasicum*, which is a dwarf and hardy shrub, much used in Germany as a stock for grafting hardy varieties.—*R. Curtisi*, Moore.—*R. multicolor* var. *Curtisi*.—*R. Dalhousiae*, Hook. f. (1). Straggling shrub, attaining 8 ft., often epiphytal: lvs. elliptic, rusty-lepidote beneath, 4–5 in. long; fls. 3–5, campanulate, yellow, changing to white, fragrant, $4\frac{1}{2}$ in. across. Himalayas. B.M. 4718. F.S. 5:466–8. Gn. 28:318; 48, p. 108. G.C. III. 33:338. F.S.R. 3:40. G. 33:579. Remarkable for the large, lily-like fragrant fls. A double-fl. variety is figured in Gn. 13, p. 517. *R. Dalhousiae* hybridum (B.M. 5322) is a hybrid with *R. formosum*, and *R. Dalhousiae* Victorianum is a hybrid with *R. Nuttallii*, see *R. Victorianum*.—*R. Davidii*, Franch. (2). Shrub, to 12 ft.: lvs. oblong-lanceolate, pale green or brownish beneath, glabrous, 4–6 in. long; fls. many, racemose, short-stalked, lilac, spotted purple, broadly campanulate, 7-lobed, $1\frac{1}{2}$ –2 in. across. W. China.—*R. Davidsonium*, Rehd. & Wilson (1). Shrub, to 10 ft.: lvs. thinly coriaceous, elliptic to oblong-lanceolate, sparingly lepidote above, densely so beneath and glaucous, 1– $2\frac{1}{2}$ in. long; fls. 1–3, axillary, rosy pink, campanulate-funnelform, 1 in. across. W. China. R.H. 1914, pp. 323, 324. B.M. 8605. Gn. 78, p. 316 (as *R. siderophyllum*).—*R. Daviesii*, Hort. Hybrid of *R. javanicum* and *R. retusum*, with tubular orange-red fls. F.M. 20:474. G.Z. 26:145. Not to be confounded with *Azalea Daviesii*, Hort., which is a Ghent azalea with white fls.; see p. 2935.—*R. decorum*, Franch. (*R. lucidum*, Franch. *R. Spooneri*, Hemsl. & Wilson. *R. erubescens*, Hutchins.) (2). Shrub: lvs. oblong, glabrous, glaucous beneath, 4–8 in. long; fls. broadly campanulate, white or pink, to 2 in. across; stamens 16. W. China. G.C. III. 47:120. G. 36:569. R.H. 1914, p. 305. B.M. 8643.—*R. Delavayi*, Franch. (2). Tree: lvs. oblong-lanceolate, rufous-tomentulose beneath: fls. in large, dense heads, deep red, broadly campanulate, 1 in. across. Yunnan. B.M. 8137.—*R. dilatatum*, Miq. (*Azalea dilatata*, Kuntze) (6). Allied to *R. rhombicum*. Lvs. rhombic-obovate, soon glabrous, 1– $2\frac{1}{2}$ in. long; fls. 1–2, lilac-purple, rotate-campanulate, $1\frac{1}{2}$ –2 in. broad. Japan. S.I.F. 2:61. G.W. 14, p. 270.—*R. discolor*, Franch. (2). Shrub, to 15 ft.: lvs. oblong or oblong-lanceolate, acute at both ends or auriculate at the base, whitish beneath, 6–8 in. long; fls. many, white to rosy pink, funnelform-campanulate, 6-lobed, 3 in. across. Cent. China.—*R. Edgarianum*, Rehd. & Wilson (1). Shrub, to 3 ft., intricately branched: lvs. broadly ovate or oval, obtuse, densely lepidote on both sides, rusty beneath, $\frac{1}{2}$ – $\frac{1}{4}$ in. long; fls. solitary, funnelform, purple, $\frac{1}{4}$ in. across. W. China.—*R. Edgeworthii*, Hook. f. Straggling shrub, often epiphytic: lvs. ovate-lanceolate, blackish green and reticulate above, ferrugineous-tomentose below, 3–4 in. long; fls. few, broadly campanulate, white, tinged rose, with broad, wavy lobes, $4\frac{1}{2}$ in. across. Himalayas. B.M. 4936. F.S. 8:797, 798. Gt. 5:228. H.F. 4:264. R.H. 1913, p. 393.—*R. Eeckhautei*, Hort. (*Azalea Eeckhautei*, Hort.). Hybrid between *R. indicum* and *R. linearifolium*. Lvs. linear-lanceolate: corolla light pink, semi-double, deeply divided into linear-oblong lobes. Very distinct; as hardy as *R. linearifolium*. R.B. 37:117.—*R. erubescens*, Hutchins.—*R. decorum*.—*R. eximium*, Nutt.—*R. Falconeri* var. *eximium*.—*R. exoniense*, Veitch. Hybrid between *R. ciliatum* and *R. Veitchianum*. Fls. white, faintly tinged rose outside, 3 in. across, very fragrant. G. 6:537; 16:663.—*R. Faberi*, Hemsl. (2). Shrub, to 18 ft.: lvs. elliptic-oblong, acute, rusty tomentose beneath like the branchlets, 3–6 in. long; fls. white to pale pink, spotted red, broadly campanulate, $1\frac{1}{2}$ in. across; calyx $\frac{1}{4}$ in. long. W. China.—*R. Falconeri*, Hook. f. (2). Shrub or tree, attaining 30 ft.: lvs. elliptic or obovate, rusty-tomentose beneath, 8–10 in. long; fls. many, campanulate, 8–10-lobed, white, with a dark purple blotch within, 1–2 in. across. Himalayas. B.M. 4924. F.S. 5:477–80; 11:1166, 1167. Gt. 19:658. Gn. 48, p. 103; 49, p. 441; 64, p. 377. G.C. III. 20:749. F.S.R. 3, p. 33. G.M. 51:203. G. 19:236; 25:22; 35:65. G.W. 14, p. 270. Remarkable for its very large lvs., sometimes to $1\frac{1}{2}$ ft. long. Var. *eximium*, Hook. Fls. rose-colored and not spotted.—*R. Fargesii*, Franch. (2). Shrub, to 15 ft.: lvs. elliptic, obtuse, subcordate at the base, glabrous, 2–3 in. long; fls. many, white to rosy pink, spotted, broadly campanulate, 6–7-lobed, $1\frac{1}{2}$ –2 in. across; stamens 12–14. Cent. China. G.C. III. 52:4. J.H. F. IV. 1:217.—*R. Farreri*, Tate (*Azalea Farreri*, Koch. *A. squamata*, Lindl.) (5). Low shrub: lvs. rhombic-obovate, subcoriaceous, 1–2 in. long; fls. pale pink or pale lilac, spotted, $1\frac{1}{2}$ in. across.

Hong-Kong. B.R. 33:3.—*R. fastigiatum*, Franch. (1). Very dwarf, flowering when only 4 in. high: lvs. closely crowded, ovate, $\frac{1}{4}$ – $\frac{1}{2}$ in. long, covered with rusty dots: fls. bright lilac-rose, $\frac{1}{2}$ –1 in. across. W. China.—*R. fastuosum* var. *flöre-pleno*, Van Houtte. Hybrid of *R. catawbiense* and *R. ponticum*. Fls. lilac-purple, semi-double. F.S. 2:143. Almost hardy.—*R. Davidum*, Franch. (1). *R. primulinum*, Hemsl. (1). Shrub, to 6 ft.: lvs. ovate-oblong, densely lepidote on both surfaces, $\frac{1}{2}$ – $\frac{3}{4}$ in. long: fls. 3–5, yellow, rotate-campanulate, $\frac{1}{4}$ in. across; stamens 10. W. China. B.M. 8326. G.C. III. 47:229. J.H.S. 36, p. 55, fig. 78.—*R. floribundum*, Franch. (2). Shrub, to 15 ft. or small tree: lvs. lanceolate, acute at both ends, slightly bullate, white or grayish tomentose beneath, 3–5 in. long: fls. 8–12, rose-colored, $\frac{1}{2}$ in. across. W. China.—*R. Fordii*, Hemsl. (2). Shrub: lvs. obovate-lanceolate, glabrous, 2–3 in. long: fls. few, white, flushed pinkish outside, $\frac{1}{2}$ in. across. S. China. B.M. 8111.—*R. formosum*, Wall. (R. Gibsonii, Paxt.). (1). Slender shrub, 8 ft. high: lvs. oblong-obovate, ciliate, pilose above, glaucous and lepidote beneath, 1–2½ in. long: fls. few, funnelform-campanulate, white, tinged pink, $\frac{1}{2}$ –2 in. across. Himalaya Mts. B.M. 4457. P.M. 8:217. G.C. III. 17:711. G.S. 157.—*R. Forsterianum*, Hort. Hybrid of *R. Edgeworthii* and *R. Veitchianum*. Fls. large, white. Gn. 76, p. 272. G.W. 3, p. 605. G. 27:251.—*R. Fortunei*, Lindl. Shrub, 12 ft. high, with stout branches, glabrous: lvs. oblong, acute, glaucous beneath, 5–7 in. long: fls. many, broadly campanulate, 7-lobed, rosy lilac; stamens 14. Cent. China. B.M. 5596. Almost hardy. Var. *Houlstonii*, Rehd. & Wilson. Lvs. narrower, smaller; pedicels more glandular.—*R. fragrans*, Maxim. (1). Low shrub: lvs. ovate-elliptic, ferrugineous-lepidote beneath, $\frac{1}{2}$ –1 in. long: fls. 10–15, yellowish white, funnelform, $\frac{1}{2}$ in. across; stamens 5. E. Siberia.—*R. fragrans*, Lodd., see No. 28, *R. azaleoides*.—*R. fragrantissimum*, Burb. Supposed hybrid between *R. ciliatum* and *R. Edgeworthii*. Fls. large, white, faintly tinged rose, fragrant. J.H. III. 57:619; 62:581.—*R. fulgens*, Hook. f. (2). Allied to *R. campanulatum*, but smaller: fls. deep blood-red, in a dense head. Himalayas. B.M. 5317. F.S. 8:789. Gn. 67:376.—*R. Gawnlettii*, Hort. Hybrid between *R. Griffithianum* and probably *R. ponticum*. Fls. pale flesh-color, changing to white, 4 in. across. G. 32:131; 34:701.—*R. gemmiferum*, Bean. Hybrid between a true rhododendron and an azalea. Dwarf shrub: lvs. deciduous or half-evergreen, oval to elliptic, obtuse or acutish, mucronulate, loosely villous on both sides, $\frac{1}{2}$ –2 in. long: fls. light carmine, funnelform-campanulate, tube somewhat longer than the lobes, $\frac{1}{2}$ in. across; stamens 5–10; style exserted, glabrous; ovary villous. Origin unknown. Hardy at the Arnold Arboretum.—*R. Gibsonii*, Paxt.=*R. formosum*.—*R. glaucum*, Hook. f. (1). Small shrub, 3 ft. high: lvs. elliptic-oblong, lepidote, glaucous beneath, 2–4 in. long: fls. 5–8; campanulate, rose-colored, $\frac{1}{2}$ in. across. Himalayas. B.M. 4721. F.S. 7:672. H.F. 1859:241.—*R. Govenianum*, Sweet. Allied to *R. azaleoides* and supposed to be a cross between a hybrid evergreen rhododendron and *R. nudiflorum* or *R. viscosum*: lvs. oblong-lanceolate, pubescent on both sides while young; fls. purplish pink; calyx-lobes linear.—*R. grande*, Wight (R. argenteum, Hook. f.). (2). Tree, to 40 ft.: lvs. oblong-obovate, acute, glabrous, white beneath, 8–12 in. long: fls. in a dense head, campanulate, 5–8-lobed, rosy at first, changing to white, 2–3 in. across. Himalayas. B.M. 5054. Gn. 48:102; 59, p. 342. F.S. 5:473–6. G.C. II. 17, suppl. J.S.R. 10; III. 4:158 (suppl.); 27:105; 45:290. R.H. 1885, p. 197. F.S.R. 3, p. 37. Gt. 30:1588. Var. *roseum*, Hook. Fls. rose-colored. B.M. 6948.—*R. Griffithianum*, Wight. Shrub, 8 ft. high, glabrous: lvs. oblong, pale beneath, 6–12 in. long: fls. 4–6, broadly campanulate, white, fragrant, 3 in. across or more. Himalayas. Gt. 15:517; 51, p. 282. G.C. III. 39:243. Var. *Aucklandii*, Hook. f. 7 in. across. B.M. 5065. Gn. 20:328. R.H. 1855:81. G.C. I. 22:657; III. 12:697. J.H. II. 57:157. Remarkable for its very large fls.—*R. hamatophyllum*, Craib=*R. creodora*.—*R. Halopendrum*, André. Hybrid of *R. arboreum* and *R. Griffithianum*. Fls. large, bluish. R.H. 1896:428.—*R. Hanceanum*, Hemsl. (1). Shrub, to 3 ft.: lvs. ovate to elliptic-lanceolate, acute, lustrous above, fulvous beneath, minutely scaly, 1–3 in. long: fls. many in dense heads, yellow, campanulate-funnelform, $\frac{3}{4}$ in. across; stamens 10. W. China.—*R. Harrisii*, Hort. Hybrid of *R. arboreum* and *R. Thomsonii*. Fls. deep crimson, spotted within.—*R. Harroianum*, Hemsl.=*R. polyplepis*.—*R. Hodgsonii*, Hook. f. Shrub or small tree, attaining 20 ft.: lvs. narrowly obovate-oblong, whitish or brownish tomentose beneath, 8–18 in. long: fls. in a dense head, broadly campanulate, pale purple, 2 in. across. Himalayas. B.M. 5552. R.H. 1855:421; 1866:191. Gn. 73, p. 588.—*R. Hookeri*, Nutt. (2). Shrub, 14 ft. high: lvs. oblong-oval, glabrous, glaucous below and sparingly chaffy on the veins: fls. campanulate, deep crimson, 1–1½ in. across; calyx cup-shaped. Himalayas. B.M. 4926.—*R. Houlstonii*, Hemsl. & Wilson.—*R. Fortunei* var. *Houlstonii*.—*R. Hunnevellianum*, Rehd. & Wilson. (2). Shrub, to 15 ft.: lvs. oblanceolate or oblong-lanceolate, acuminate, glabrous above, white-tomentose beneath, 3–4½ in. long: fls. many, white, spotted, broadly campanulate, 2 in. across. W. China.—*R. hypoglauca*, Hemsl. (2). Lvs. elliptic, acute, 2–3 in. long: corolla snow-white; segms. notched. Cent. China. B.M. 8649.—*R. imbricatum*, Hort. Apparently a hybrid of *R. ponticum* with a hardy species of the same group. Dwarf, very compact shrub: lvs. crowded, oblong, obtuse, glabrous, lustrous, convex and somewhat bullate above, 1¼–2½ in. long: pedicels puberulous: fls. pale lilac-purple, 2 in. across; style and the sometimes petaloid stamens short; ovary glabrous. Origin unknown. Hardy at the Arnold Arboretum.—*R. insigne*, Hemsl. & Wilson. (2). Shrub, to 18 ft.: lvs. lanceolate-oblong, acute at both ends, lustrous above, grayish tomentose beneath, 3¼–5 in. long: fls. many, pink to white, broadly campanulate, 1½–2 in. across; stamens 14 or more. W. China.—*R. intermedium*, Tausch. Hybrid between *R. ferrugineum* and *R. hirsutum* and intermediate between the two. Has been found occasionally with the parents.—*R. intricatum*, Franch. (1). Shrub, to 3 ft.: lvs. elliptic or ovate, obtuse, densely lepidote on both

sides, silvery beneath, $\frac{1}{4}$ – $\frac{3}{4}$ in. long: fls. 3–5, rosy purple, funnel-form, $\frac{1}{2}$ in. across. W. China. B.M. 8163. G.C. III. 41:262. Gn. 78:190, 294. R.B. 35, p. 108. J.H.S. 33, p. 49, fig. 21. J.H. III. 54:343. M.D.G. 1909:145.—*R. irroratum*, Franch. Shrub, several feet high, glabrous: lvs. oblong to oblong-lanceolate, pale beneath, 3–4 in. long: fls. many, funnelform-campanulate, $\frac{1}{2}$ in. long, white, tinged pink. Yunnan. B.M. 7361. G.C. III. 49:350.—*R. Jacksonii*, Hort. (G. 28:183) is said to be the same as *R. venustum*.—*R. javanicum*, Blume (1). Large shrub, glabrous: lvs. elliptic to oblong, acute, minutely lepidote beneath, 3–6 in. long: fls. many, funnel-form, orange-yellow to brick-red, 2 in. across. Winter. Malayan Archipelago and Penin. B.M. 4336. F.S. 3:293, 294; 6:576. P.M. 15:217. Var. *tubiflorum*, Hook. Lvs. smaller: fls. smaller and with longer tube, salmon-pink. B.M. 6850.—*R. Jenkinsii*, Nutt.=*R. Maddenii*.—*R. kantschaticum*, Pall. (Azalea kantschatica, Kuntze). Belongs to the section Therodion, characterized by the fls. being borne at the end of the young branchlets. Prostrate undershrub: lvs. deciduous, obovate or spatulate, obtuse, ciliate, $\frac{1}{4}$ – $\frac{2}{3}$ in. long: fls. 2–3, in terminal racemes, rotate-campanulate, $\frac{1}{2}$ in. long: fls. carmine-purple, spotted; stamens 10; ovary pilose. E. Siberia, N. Japan and Alaska. B.M. 8210. Gt. 36:1260. G.C. III. 44:128. G.W. 13, p. 554. Hardy, but difficult to cult.—*R. Kendrickii*, Nutt. (2). Large shrub: lvs. lanceolate, acuminate, glabrous, pale beneath, 4–7 in. long: fls. many, campanulate, bright scarlet, 2 in. across. Himalayas. Var. *latifolium*, Hook. Lvs. broader, oblong-lanceolate, glandular pubescent beneath when young. B.M. 5129.—*R. Kesselringii*, Wolf. Hybrid between *R. ponticum* and *R. Smirnovii*. Low shrub: lvs. soon glabrous beneath: fls. rosy purple with darker margin.—*R. kewense*, W. Wats. Hybrid of *R. Griffithianum* and *R. Hookeri*. Fls. large, in loose heads, crimson, pink or almost white. Gn. 42:474; 52:284; 76, p. 319. G.C. III. 23:291. G.M. 44:356; 50:211.—*R. Këysii*, Nutt. Belongs to the section Keyia characterized by the tubular corolla with short erect lobes. Shrub, 2–6 ft. high, with ferrugineous branches: lvs. elliptic-lanceolate, glabrous, pale and sparingly scaly beneath, 3–4 in. long: fls. many, tubular, with short erect lobes, brick-red, 1 in. long: fls. many. Himalayas. B.M. 4875. F.S. 11:1110. Gt. 12:415. Gn. 48, p. 106.—*R. Kötschyi*, Simonkai (R. myrtifolium, Schott & Kotschy, not Lodd.). (1). Low shrub: lvs. oblong-obovate, obtuse, mucronulate, shining above, ferrugineous-lepidote beneath, $\frac{1}{2}$ –1 in. long: fls. few, tubular-funnelform, with the tube outside pubescent, inside villous, carmine, $\frac{1}{2}$ in. long; style shorter than ovary. July. Carpathian Mts. Gn. 56, p. 159. R.F.G. 17:1157, figs. 2, 3.—*R. laetum*, Franch. (2). Tree, to 30 ft.: lvs. cordate, elliptic-ovate, brownish tomentulose beneath, 5–10 in. long: fls. in dense heads, broadly campanulate, 6-lobed, white, 1 in. across. Yunnan. B.M. 8372. R.H. 1912, pp. 375, 376.—*R. landium*, Hook. f. (2). Shrub or small tree: lvs. ovate to obovate-oblong, with tawny woolly tomentum beneath, and also above when young, 3–5 in. long: fls. 6–10, broadly campanulate, yellow, spotted red within, 2–2½ in. across. Himalayas. F.S. 7:684. R.H. 1855:161. Almost hardy.—*R. lancifolium*, Moench=*R. ponticum*.—*R. lancifolium*, Hook. f.=*R. barbatum*.—*R. lapponicum*, Wahl. (1). Depressed shrub: lvs. oval or oblong, obtuse, $\frac{1}{4}$ – $\frac{1}{2}$ in. long: fls. 3–6, broadly campanulate, purple, $\frac{1}{2}$ in. across; stamens 5–8. July. Mountains of N. Amer., N. Eu., N. Asia. B.M. 3106. M.D.G. 1910:136. Hardy.—*R. lepidotum*, Wall. (R. elaeagnoides, Hook. f.). (1). Slender shrub, 4 ft. high: lvs. ovate to lanceolate, glaucous-green, lepidote beneath, $\frac{1}{2}$ –1½ in. long: fls. 1–3, sometimes many, slender-pedicelled, broadly campanulate, yellow or dull purple, spotted within, $\frac{1}{2}$ in. across; stamens usually 8. Himalayas. B.M. 4657. Gn. 15:182. G.C. II. 22:297. J.F. 4:343. Var. *chloranthum*, Hook. (R. salignum, Hook. f.). Fls. greenish or pale yellow, spotted greenish: lvs. narrow. Var. *obovatum*, Hook. Fls. dark purple, larger: lvs. ovate.—*R. linearifolium*, Sieb. & Zucc. (Azalea linearifolia, Hook.) (6). Allied to *R. ledifolium*. Lvs. linear-lanceolate: corolla pink, deeply divided into 5 linear-lanceolate segms. Japan. B.M. 5769. G.M. 36:104.—*R. Lobtii*, Veitch (1). Slender shrub, allied to *R. malayanum*: lvs. elliptic-oblong: fls. almost salver-shaped, with slender, curved tube, bright crimson. Winter. Borneo. The *R. Lobbianum*, Moore (F.M. 1:10), belongs to *R. Brookianum*.—*R. Loderi*, Hort. Hybrid between *R. Fortunei* and *R. Griffithianum*. Fls. white to soft rose, 6-lobed, 5–6 in. across, fragrant. G.C. III. 50:30; 61:360. Not to be confused with *Loderi* hybrid which is a cross of unknown origin, apparently also of *R. Griffithianum*.—*R. longesquamatum*, Schneid. (R. Bretti, Hemsl.) (2). Shrub, to 15 ft.: scales of lf-buds persistent, elongated: lvs. obovate-oblong, acute, rounded at the base, glabrous beneath except the villous midrib and petiole, 2½–5 in. long: fls. 6–15, rosy pink, campanulate, 2 in. across. W. China.—*R. longistylum*, Rehd. & Wilson. (1). Allied to *R. micranthum*. Shrub, to 6 ft.: lvs. oblanceolate or oblong-lanceolate, sparingly lepidote beneath, 1–2½ in. long: fls. 10 or more, white, funnelform-campanulate, $\frac{1}{2}$ in. across; style exserted, 1 in. long. W. China. R.H. 1914, pp. 232, 233.—*R. lucidum*, Franch.=*R. decorum*.—*R. Luscombei*, W. Wats. Hybrid of *R. Fortunei* and *R. Thomsonii*. Fls. large, rose-red to crimson. Gn. 66, p. 392. G. 26:528.—*R. lutescens*, Franch. (1). Allied to *R. racemosum*. Lvs. lanceolate or ovate-lanceolate, long-acuminate, sparingly lepidote, light green beneath: fls. 1–3, from axillary heads, 1 in. across, yellow; stamens 10, exserted. W. China. R.H. 1914:324.—*R. macrocarpos*, Griff.=*R. Dalhousiae*.—*R. macrosepalum*, Maxim. (Azalea macrosepala, Kuntze.) (6). Shrub, to 2 ft.: branchlets villous: lvs. deciduous or subsistent, elliptic, 1–2 in. long: fls. umbellate, rose-lilac, spotted, 2 in. across; sepals lanceolate, long, glandular-pubescent. Japan. Gt. 19:662. Azalea dianthiflora, Carr. (R.H. 1891:60) is possibly a double-fld. form of this species.—*R. macrostemon*, Maxim. (6). Low half-evergreen shrub: lvs. oblong-elliptic, pubescent, about $\frac{1}{2}$ in. long: fls. pinkish, $\frac{1}{4}$ –1 in. across; stamens twice as long as corolla. Japan.—*R. Maddenii*, Hook. f. (1). Shrub, to 8 ft.: lvs. short-stalked, elliptic-lanceolate, ferrugineous-lepidote beneath, 4–7 in. long: fls.

3, funnel-shaped, white, faintly blushed, to 4 in. across; stamens 18-20. Himalayas. B.M. 4805. F.S. 9:912. R.H. 1855:301. I.H. 4:140. Gt. 9:277 (as R. Jenkinsi). H.F. 7:296. Var. *obtusifolium*, Hutchins. Lvs. rounded at both ends; calyx-lobes longer. Manipur. B.M. 8212.—*R. malayanum*, Jack. (1). Small shrub or small tree: lvs. elliptic-lanceolate, red-brown-lepidote beneath, 3-4 in. long; fls. few, salver-shaped, dull scarlet, $\frac{3}{4}$ in. long. Winter. Malacca, Java. B.M. 6045.—*R. Manglesii*, Hort. Hybrid of R. Griffithianum and R. hybridum album elegans. Fls. large, white, spotted. G.C. II. 24:49; III. 12:767. G. 66, p. 393; 69, p. 329. F.S.R. 3, p. 39. G. 13:101.—*R. Maresii*, Hemsl. & Wilson (6). Allied to R. rhombicum. Shrub, to 8 ft.: lvs. oval, acute, silky-pubescent on the midrib beneath, 2-3 in. long; fls. 1-3, rose-pink, broadly campanulate, $\frac{1}{2}$ in. across; stamens 10. Cent. China. B.M. 8206.—*R. modestum*, Hook. f. (1). Small shrub, glabrous: lvs. elliptic-oblong, greenish yellow and lepidote beneath, 2-3 in. long; fls. 6-10, broadly funnelform, pale pink, spotted red within, $\frac{1}{2}$ in. across. Himalayas. B.M. 7686.—*R. Moorei*, Wats. Hybrid between R. arboreum and R. campanulatum. Fls. large, white spotted purplish: lvs. with buff-colored tomentum beneath.—*R. Morelianum*, Lem. Hybrid between R. catawbiense and probably R. ponticum. Fls. lilac-violet, with a whitish blotch spotted with yellow. H.U. 4:1.—*R. moumainense*, Hook. (2). Shrub: lvs. elliptic-lanceolate, glabrous, 4-5 in. long; fls. many, white, funnelform-campanulate, $\frac{1}{2}$ -2 in. across. Himalayas. B.M. 4904.—*R. moupinense*, Franch. (1). Shrub, to 4 ft., sometimes epiphytic: lvs. ovate to ovate-oblong, obtuse, rusty lepidote beneath, 1-1 $\frac{1}{2}$ in. long; fls. solitary, white, spotted purple, $\frac{1}{2}$ in. across. W. China. B.M. 8598. G.C. III. 55:133. R.H. 1914, p. 155. G. 78, p. 96.—*R. multicolor*, Miq. Small, slender shrub: lvs. whorled, narrowly elliptic-lanceolate, 2-3 in. long; fls. few, funnelform-campanulate, 1 in. long, yellow or dark red. Winter. Sumatra. B.M. 6769. Tender. The red-fld. form is distinguished as var. *Curtisii*, Hort. G. 56, p. 62. F. 1884:113. G.Z. 30:73.—*R. myrtifolium*, Schott & Kotschy, not Lodd.—*R. Kotschyi*,—*R. nigro-punctatum*, Hort., not Franch.—*R. nitidulum* var. *nubigenum*.—*R. nipponicum*, Matsum. (5). Shrub: lvs. deciduous, elliptic-obovate, obtuse, strigose on the veins beneath and sparingly strigose above, $2\frac{1}{2}$ -7 in. long; fls. in dense heads, white, sub-campanulate, $\frac{2}{3}$ in. long; stamens 10, about as long as the corolla; style glabrous; ovary villous. Japan.—*R. nitidulum*, Rehd. & Wilson (1). Shrub, 2-4 ft.: lvs. oval or ovate, densely lepidote on both sides, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; fls. 1-2, violet-purple, funnelform-rotate, 1 in. across. W. China. Var. *nubigenum*, Rehd. & Wilson (R. nigro-punctatum, Hort., not Bur. & Franch.). One-half to 1 ft., densely branched: lvs. $\frac{1}{2}$ - $\frac{1}{2}$ in. long, brown beneath: fls. rosy lilac, $\frac{3}{4}$ in. across; calyx large, usually colored. W. China. B.M. 8529.—*R. niveum*, Hook. f. (2). Small shrub, allied to R. campanulatum: lvs. obovate-oblong, whitish tomentose all over at first, later glabrous above, 3-6 in. long; fls. broadly campanulate, light rose-lilac at the base, within with 5 purple spots, 2 in. across. Himalayas. B.M. 4730. J.F. 4:421. Var. *fulvum*, Hook. Lvs. light brownish tomentose: fls. deep purple-lilac. B.M. 6827.—*R. Nobleianum*, Lindl. Hybrid of R. arboreum and R. caucasicum. Fls. rosy crimson. B.R. 1820. G. 77, p. 30.—*R. Nuttallii*, Booth (1). Shrub, sometimes epiphytic or tree 30 ft. high: lvs. elliptic-oblong, reticulate, pale and lepidote beneath, 6-12 in. long; fls. 4-12, broad funnelform, white, tinged yellow within, fragrant, to 6 in. across; calyx large. Himalayas. B.M. 5146. F.S. 13:1326, 1327. G. 54, p. 106; 79, p. 290. G.C. II. 20:49; III. 12:436 (suppl.). R.B. 31:145. G.Z. 2:96. R.H. 1913:452.—*R. obovatulum*, Hook. f.—*R. lepidotum* var. *obovatulum*.—*R. orbiculare*, Deane. (R. rotundifolium, David) (2). Lvs. nearly orbicular, 2-4 in. long, usually not so broad as long; fls. 8-10; corolla 2 in. across, rosy red. W. China.—*R. oreodora*, Franch. (R. hamatochilum, Craib). (2). Shrub, to 10 ft.: branchlets soon glabrous: lvs. elliptic-lanceolate, glabrous, yellowish green beneath, $2\frac{1}{2}$ -3 $\frac{1}{2}$ in. long; fls. 10-12, rose-pink, campanulate, 7-8-lobed, $\frac{1}{2}$ in. across. W. China. B.M. 8518.—*R. ovoidum*, Planch. (Azalea ovata, Lindl. A. myrtifolia, Champ.) (3). Lvs. ovate or elliptic-ovate, glabrous, 1-2 in. long; fls. rotate, pink or nearly white, $\frac{1}{2}$ in. across; stamens 5. Cent. China. B.M. 5064. J.H.S. 1847:126.—*R. pachytrichum*, Franch. (2). Shrub, to 18 ft.: lvs. narrow, oblong-lanceolate, acuminate, rounded at base, rufously hairy on the midrib beneath and on the petiole, $2\frac{1}{2}$ -5 in. long; fls. 10-15, campanulate, $\frac{1}{2}$ in. across, pale pink to white; stamens 10. W. China.—*R. parvifolium*, Adams (1). Shrub allied to R. lapponicum, but larger: 3 ft. high: lvs. not revolute at the margin, larger: fls. larger, purple or white; style much longer than stamens. Siberia. Kamchatka, Japan. Gt. 26:904. G.C. III. 39:164, 165.—*R. pendulum*, Hook. f. (2). Slender shrub, 4 ft. high: lvs. elliptic to oblong, acute, ferrugineous-tomentose beneath, $\frac{1}{2}$ -2 in. long; fls. few, broadly campanulate, white, about 1 in. across. Himalayas. F.S. 7:662. G.C. II. 17:429.—*R. pentaphyllum*, Maxim.—*R. quinquefolium*, Franch. (R. Harrovianum, Hemsl.) (1). Shrub, to 10 ft.: lvs. lanceolate, acute at both ends, glabrous above, densely lepidote beneath, $\frac{1}{2}$ -3 in. long; fls. 3-5, purple or lilac-purple, $\frac{1}{2}$ in. across; stamens 10, exserted. W. China. B.M. 8309. R.H. 1914:324.—*R. primulinum*, Hemsl.—*R. flavidum*,—*R. Przewalskii*, Maxim. (2). Allied to R. brachycarpum, but lvs. glabrous and pale green beneath: fls. white, spotted purple within. China. Hardy.—*R. pulcherrimum*, Lindl. Hybrid of R. arboreum and R. caucasicum. Fls. pink, paler in center, spotted. B.R. 1820.—*R. quinquefolium*, Bisset & Moore (6). Deciduous shrub: lvs. 4-5, subterriculate at the end of the branchlets, short-petioled, rhombic, acutish or obtuse, ciliate and sparingly strigose-pubescent, 1-1 $\frac{1}{2}$ in. long; fls. 1-2, campanulate, 3 in. across; stamens 10. Japan. Var. *roseum*, Rehd. Fls. pink; possibly identical with R. pentaphyllum, Maxim.—*R. retisum*, Bennett (1). Shrub, 2 ft. high: lvs. obovate to obovate-oblong, glabrous, lepidote beneath, 2-2 $\frac{1}{2}$ in. long; fls. 6-9, tubular-funnel-shaped, bright scarlet, to

1 $\frac{1}{2}$ in. long. Java. B.M. 4859. F.S. 10:1044. I.H. 2:70. Tender.—*R. Rietii*, Hemsl. & Wilson (2). Shrub, to 18 ft.: lvs. lanceolate or oblong-lanceolate, acute at both ends, glabrous and grayish below, 4-6 in. long; fls. about 10, white, 2 in. across. W. China.—*R. robustissimum*, Lindl.—*R. fastuosum*.—*R. Rollissonii*, Paxt. (2). Small tree, 30 ft. high, allied to R. arboreum and probably variety: lvs. oblong, wrinkled above, tawny-tomentose beneath: fls. in a dense head, campanulate, deep blood-red. Ceylon. B.R. 29:25.—*R. rotundifolium*, David.—*R. orbiculare*.—*R. Roylei*, Leroy. Hybrid of R. arboreum and R. dahuricum. Fls. rich crimson. R.H. 1863:190.—*R. Roylei*, Hook.—*R. cinnabarinum* var. *Roylei*.—*R. rubiginosum*, Franch. (1). Rigid shrub, 3 ft. high: lvs. oval to oblong-lanceolate, densely ferrugineous-lepidote beneath, 2-3 in. long; fls. few, broadly funnelform, bright rose-red, $\frac{1}{2}$ in. across. Yunnan. B.M. 7621.—*R. rufescens*, Franch. (1). Shrub, to 4 ft.: lvs. oval, brown-tomentose beneath, $\frac{1}{2}$ -1 in. long; fls. white, about $\frac{1}{2}$ in. across. W. China.—*R. Russellianum*, Sweet. Hybrid of R. arboreum and R. catawbiense. Lvs. tomentose beneath: fls. rosy crimson.—*R. salignum*, Hook.—*R. lepidotum* var. *chloranthum*.—*R. Sargentianum*, Rehd. & Wilson. (1). Alpine shrub, 1-2 ft.: lvs. oval, obtuse, and mucronulate, rusty-tomentose beneath, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; fls. 6-12, funnelform, whitish or pale yellow, $\frac{1}{2}$ in. across; stamens 5; calyx large. W. China.—*R. scabrifolium*, Franch. (1). Small rigid shrub, hispid: lvs. oblong-lanceolate, ciliate, hispid above, pale and lepidote beneath, $2\frac{1}{2}$ -3 $\frac{1}{2}$ in. long; several few-fld. clusters at the end of branches: fls. broadly campanulate, bluish, $\frac{1}{2}$ in. across. Yunnan. B.M. 7159.—*R. Searsii*, Rehd. & Wilson. (1). Shrub, to 15 ft.: lvs. oblanceolate to oblong-lanceolate, acuminate, glaucouscent and lepidote beneath, $1\frac{1}{2}$ -3 in. long; fls. 4-8, funnelform-campanulate, $\frac{1}{2}$ in. across, white or pale purple. W. China. G.C. III. 55:334.—*R. semibarbatum*, Maxim. (Azalea semibarbatum, Kuntze) (3). Allied to R. albiflorum. Lvs. elliptic, crenately ciliate, setose beneath: fls. greenish yellow, spotted purple, $\frac{1}{2}$ - $\frac{3}{4}$ in. broad. Japan. Gt. 19:666.—*A. serpyllifolium*, Miq. (Azalea serpyllifolia, Gray) (6). Low, rigid shrub: lvs. deciduous, obovate, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; fls. single, rosy red, $\frac{1}{2}$ - $\frac{3}{4}$ in. broad. Japan. B.M. 7503.—*R. Sesterianum*, Hort. Hybrid of R. Edgeworthii and R. formosum. Fls. large, white. G. 17:383; 20:701. R.H. 1906, p. 488.—*R. setosum*, D. Don (1). Shrub, about 1 ft.; branchlets setose: lvs. elliptic-obovate or oblong, lepidote on both sides, setosely ciliate, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; fls. rosy purple, nearly rotate, deeply divided, about 1 in. across. E. Himalayas. B.M. 8523.—*R. Shilona*, Hemsl. & Wilson (2). Evergreen shrub, 4-6 ft. high: lvs. oval or ovate, $2\frac{1}{2}$ -4 in. long, quite glabrous; petiole $\frac{1}{2}$ -1 in. long; corolla broadly campanulate, 7-lobed, $\frac{1}{2}$ in. across, pink. W. China.—*R. Shpherdii*, Nutt. (2). Shrub: lvs. oblong-lanceolate, glabrous, pale beneath, 3-4 in. long; fls. in a dense head, campanulate, deep scarlet, 2 in. across. Himalayas. B.M. 5125.—*R. Shilonii*, Hort. Hybrid of R. barbatum and R. Thomsonii. Fls. dull red. G. 57, p. 261.—*R. siderophyllum*, Hort., not Franch.—*R. Davidsonianum*,—*R. Smithii*, Sweet. Hybrid of R. arboreum and R. ponticum. Fls. rose-purple. Var. *album*, Hort. Fls. white, early.—*R. Smithii*, Nutt.—*R. barbatum* var. *Smithii*.—*R. Smithii aureum*, Hort. See under No. 28. R. azaleoides.—*R. Souliei*, Franch. (2). Shrub, to 10 ft.: lvs. broadly ovate, cordate, mucronulate, glabrous, whitish beneath, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. long; fls. 5-7, rose-pink, broadly campanulate, with short rounded lobes. W. China. B.M. 8622. G.C. III. 45:380. G. 73, p. 278. G.M. 52:416. J.H.S. 35, p. 137, fig. 89.—*R. spinuliferum*, Franch. (1). Shrub, to 8 ft.; branchlets finely gray, pilose and hispid: lvs. lanceolate, acute at both ends, wrinkled above, lepidote and slightly pilose beneath, 1-1 $\frac{1}{2}$ in. long; fls. usually 4, red, tubular, with upright lobes, 1 in. long; stamens exserted. S. W. China. B.M. 8408. R.H. 1910:404.—*R. Spooneri*, Hemsl. & Wilson.—*R. decorum*.—*R. stamineum*, Franch. (R. pittosporifolium, Hemsl.) (3). Shrub, to 20 ft.: lvs. obovate-oblong to elliptic-oblong, acuminate, glabrous, $2\frac{1}{2}$ -4 in. long; fls. many, white to pink, spotted yellow, funnelform with long narrow tube, 1-1 $\frac{1}{2}$ in. long, fragrant. Cent. and W. China. B.M. 8601.—*R. strigulosum*, Franch. (2). Shrub, to 15 ft.: branchlets and petioles setose; lvs. oblong-lanceolate, subcordate at the base, with crustaceous white tomentum and setose hairs beneath, 4-6 in. long; fls. many, white to purple, funnelform-campanulate, $\frac{1}{2}$ in. across. W. China.—*R. subanceolatum*, Miq. (Azalea subanceolata, Kuntze) (6). Allied to R. poukhanense. Lvs. narrow-elliptic to oblanceolate, acute at both ends, with 5-9 pairs of veins, strigose on the veins on both sides, $1\frac{1}{2}$ -2 in. long; fls. 1-3; sepals oblong obtuse, strigose and glandular-ciliate; corolla funnelform, rosy red to crimson, 3 in. across; stamens 10. S. Japan. B.M. 8478. G.C. III. 49:342. J.H.S. 37, p. 131, fig. 115.—*R. taliense*, Franch. (2). Shrub, to 10 ft.: lvs. ovate-oblong, subcordate, short-acuminate, fulvous-tomentose beneath, $2\frac{1}{2}$ -5 in. long; fls. 3-12, white to pink, funnelform-campanulate, 1 in. across; ovary glabrous. W. China.—*R. Teymannii*, Miq. (1). Closely allied to R. javanicum: lvs. more shining, not lepidote beneath: fls. somewhat smaller, pale lemon-yellow. Sumatra, Java.—*R. Thomsonii*, Hook. f. (2). Shrub, 15 ft. high: lvs. obovate-oval, glabrous, glaucouscent beneath, 2-3 in. long; fls. 6-8, campanulate, deep blood-red, 2 in. across; calyx large. Himalayas. B.M. 4997. R.H. 1855:121. F.S. 7:688-90. G. 28:247; 36:535.—*R. trichostomum*, Franch. (1). Shrub, to 6 ft.: lvs. ovate-oblong to elliptic-lanceolate, rusty-tomentose beneath, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; fls. 10-15, rose-pink, tubular-funnelform, $\frac{1}{2}$ in. across, mouth hairy; stamens included. W. China.—*R. trifidum*, Hook. f. (1). Shrub, 6 ft. high: lvs. ovate-lanceolate, glabrous beneath and with ferrugineous scales, 2-3 in. long; fls. mostly 3, slender-pedicelled, broadly campanulate, greenish yellow, 2 in. across. Himalayas. F.S. 7:673. G.C. II. 18:45. J.H. III. 30:193. G. 26:282.—*R. Tschonoskii*, Maxim. (Azalea Tschonoskii, Kuntze) (6). Low shrub: lvs. elliptic, $\frac{1}{2}$ - $\frac{1}{2}$ in. long; fls. 2-4, white, $\frac{1}{2}$ in. broad. Japan.—*R. tubiflorum*, DC.—*R. malayanum*,—*R. Ungernii*, Trautv. (2). Closely allied to R. Smirnovii, but fls. white: calyx

with longer, narrower lobes. July. Caucasus. Gt. 35:1226. B.M. 8332.—*R. Veitchianum*, Hook. (1). Shrub, 6 ft. high: lvs. obovate, glaucous beneath and with scattered ferrugineous scales, 3-4 in. long: fls. 3-5, broadly funnelform, with crisped lobes, pure white, 5 in. across. Himalayas. B.M. 4992. F.S. 14:1416. A.F. 11:145. Gn. 51, p. 178. G.M. 45:476. G. 19:664, 26:71. Var. *levigatum*, Hort. Lobes of corolla only slightly crisped.—*R. penistum*, Sweet. Hybrid of *R. arboreum* and *R. caucasicum*. Fls. rich pink.—*R. Victorianum*, Hort. (*R. Dalhousiae* and *R. Nuttallii*). Fls. very large, to 5 in. long and to 3½ in. wide, white, with yellow center: lvs. glaucous beneath. F.S. 23:2466. R.B. 13:49. G.C. III. 51:406. G. 35:311.—*R. villosum*, Hemsl. & Wilson. (1). Evergreen shrub, to 18 ft., bristly: lvs. ovate or oblong, pointed, 2-3½ in. long: fls. in clusters of 3 or more; corolla with funnel-shaped tube and a 5-lobed limb, purple. W. China.—*R. molaceum*, Rehd. & Wilson (1). To 4 ft., but sometimes dwarf: lvs. similar to those of *R. intricatum*, but narrower, yellowish or brownish lepidote beneath with scattered dark scales, revolute at margin: fls. 1-3, terminal, subsessile; corolla violet-purple, over 1 in. across. W. China.—*R. virgatum*, Hook. f. (1). Slender shrub: lvs. oblong-lanceolate, glaucous and scaly beneath: fls. 1-2, from axillary buds at the end of branches, funnelform, rose-colored, 1¼ in. across. Himalayas. B.M. 5060. F.S. 14:1408. Var. *dibum*, Hort. Fls. white. R.H. 1866:251.—*R. Watsonii*, Hemsl. & Wilson (2). Shrub, to 6 ft.: lvs. ovate to ovate-lanceolate, acute, brown-tomentose beneath, 2-3 in. long: fls. about 6, rose-pink to white, campanulate, 1½-2 in. across. W. China.—*R. Watsonii*, Hemsl. & Wilson (2). Shrub or small tree, to 30 ft.: lvs. ovate to ovate-lanceolate, slightly wrinkled above, brownish tomentose beneath, 2-3 in. long: fls. 6, funnelform-campanulate, 2 in. across, pink or creamy white. W. China.—*R. Websterianum*, Rehd. & Wilson (1). Shrub, to 3 ft.: lvs. ovate or elliptic, obtuse, lepidote above, densely whitish lepidote beneath, 1¼-1½ in. long: fls. 1-3, funnelform, rosy purple, 1 in. across. W. China.—*R. Wightii*, Hook. f. (2). Shrub, attaining 14 ft.: lvs. ovate-oblong, cinnamonaceous-tomentose beneath, 6-8 in. long: fls. many, campanulate, yellow, spotted red within, 2½ in. across. Himalayas. F.S. 8:792, 793. B.M. 8492. G.C. III. 50:269.—*R. Williamsianum*, Rehd. & Wilson (2). Branchlets slender, almost twigg, diffusely branching: lvs. ovate or roundish-ovate, usually subcordate, glabrous, ¾-1½ in. long: fls. 3-5 in a terminal cluster; corolla pale rose. W. China.—*R. Willmothii*, Hort. = *R. Hanceanum*.—*R. Wilsonae*, Hemsl. & Wilson. (3). An evergreen shrub, to 6 or 7 ft.: lvs. narrowly oval or oval-lanceolate, 2½-4½ in. long: fls. solitary, axillary, slightly fragrant; corolla pale purple, about 2 in. across. Cent. China.—*R. Wilsonii*, Hemsl. & Wilson. (2). Evergreen shrub, to 8 ft. high: young shoots, underside of lvs. and ovary densely clothed with pale brown wool: lvs. deeply wrinkled, obovate, 2-3½ in. long: fls. in clusters of 6 or more; corolla pink. W. China.

ALFRED REHDER.

RHODOLEIA (Greek, *rose* and *smooth*; alluding to rose-like fls. and smooth st.). *Hamamelidaceæ*. Small tender trees: lvs. evergreen, glabrous, long-stalked: fls. about 5 together in a compact head, having the appearance of a single fl. surrounded by bracts, hermaphrodite; petals of each fl. turned toward the circum. of the head; stamens 7-10; ovary of 2 carpels united at base: caps. several-seeded.—Two species, one from China and the other from Java and Sumatra.

Championii, Hook. A tender tree: lvs. shining, coriaceous, usually ovate, 4-5 in. long; petioles 1½-2 in. long: fl.-heads resembling a semi-double camellia, 1½ in. across, bright pink, each head surrounded by several rows of imbricate bracts; petals 15-20 to each fl.-head. China. B.M. 4509. J.F. 1:4.—Formerly in cult. in S. Calif.

F. W. BARCLAY.

RHODOMYRTUS (Greek, *rose-myrtle*, from the rose-colored flowers). *Myrtaceæ*. Tender trees and shrubs, one of which, *R. tomentosa*, is of slight economic importance in southern Asia, where it is native, and which is grown to a limited extent in California and Florida.

Leaves opposite, 5- or 3-nerved: fls. rather large, axillary; calyx-tube turbinate, the lobes persistent; petals 5 or 4; stamens numerous, free, in many series; berry globose or ovoid, with few to many seeds.—Species about 5. The genus differs from *Myrtus* in having 1-3 locules in the ovary with 2 rows of ovules in each, the locules frequently with spurious partitions or divided into numerous 1-ovulate superposed cells; while the lvs., in place of being pinnately veined, have 3-5 nerves. *R. tomentosa* is indigenous to India, Ceylon, Malaya, and S. China. The other species are Australian and not cult.

tomentosa, Wight (*Myrtus tomentosa*, Ait.). **DOWNY MYRTLE**. **HILL-GOOSEBERRY**. Small shrub, up to 5 ft.,

the young branchlets tomentose: lvs. elliptic or obovate, obtuse, 1-2½ in. long, hoary below; petioles short: fls. 1-3 on slender peduncles about half the length of the lvs., rose-pink, ½-¾ in. broad; calyx tomentose, 5-cleft, the lobes unequal; petals downy outside, shortly clawed: berry globose, ½ in. broad, dull purple, 3-celled, with numerous small compressed seeds in each cell. B.M. 250.—This plant seems to be best known in S. India, where it occurs commonly in the mountains. It is said by Macmillan to succeed in Ceylon only at high elevations. In S. China the fr. is sometimes offered in the markets. While intro. to Fla. some years ago, it is not generally grown in that state, although it is an excellent garden plant of ornamental as well as economic value. According to Reasoner it grows as far north as Putnam County; it succeeds remarkably at Bradentown, where it has almost become naturalized in one or two spots, and it is successfully grown at Miami. In Calif. it has fruited in a few gardens. It does not stand very much frost, although it is hardier than some of the strictly tropical frs. The guava-like fr. is about the size of a gooseberry, of a dull purple color, with numerous small seeds embedded in soft pulp of sweet pleasant flavor, somewhat suggesting the raspberry but rather lacking in character. According to Simpson, it makes excellent pies, if picked before fully ripe. The season in Fla. is early summer, at which time the plants are laden with fr. The fls., which appear in spring, resemble small single roses, and are of unusually attractive appearance, making the plant highly ornamental while in bloom. Frequently the frs. ripen over a period of several weeks. In India, according to Hooker, they are made into a jam called thaonti, and are also eaten while fresh. The plant does not seem to be particular regarding soil, thriving upon heavy loam or light sand. It is readily prop. by seeds, which should be sown in flats of light soil soon after they are removed from the fr., covering them to the depth of ½ in. and pricking off the young plants when 2 in. high. When set out in the open ground the plants do not grow very rapidly, but are of simple cult. In dry climates they require plenty of water.

F. W. POPENOE.

RHODORA: *Rhododendron canadense*.

RHODORHIZA (Greek, *rose root*; the root and wood furnish the fragrant powder known as *bois de rose*). *Convulvulaceæ*. Rhodorhiza is a group of about 7 species, all from the Canary Isls., which Bentham & Hooker and some other authors regard as a section of the genus *Convolvulus*. The Rhodorhizas differ from typical *Convolvulus* in having the caps. by abortion usually 1-seeded, and rupturing irregularly at the base instead of dehiscing by 4 valves. They are prostrate or climbing herbs or erect subshrubs, sometimes spinescent: lvs. entire, dentate, undulate or lobed: corolla broadly or narrowly bell-shaped; limb 5-angled or 5-lobed; ovary 2-loculed, 4-ovuled.

florida, Webb. (more properly *Convolvulus floridus*, Linn. f.). Erect subshrub: lvs. persistent, alternate, lanceolate, stalked, entire: fls. long-peduncled, funnel-shaped, white, sometimes pinkish white. Isl. of Tenerife. R.H. 1892:156.—*R. florida* is a tender subshrub, 6-9 ft. high, which bears white fls. something like a morning-glory. The blossoms are about an inch across and last only a day, but a succession is maintained (in S. France) from early June till Aug. A striking feature of the plant is its terminal, panicked infl. These panicles are often a foot high, 10 in. wide at the base and contain at one time as many as 20 full-blown fls. and 100 buds. Intro into S. Calif.

scoparia, Webb. (more properly *Convolvulus scoparius*, Linn. f.). Shrubby: sts. terete and glabrous: lvs. linear and rather pilose: fls. white, generally 3 to a peduncle, hairy outside; calyx silky, the sepals ovate, acute. Aug. and Sept. Isl. of Tenerife. B.R. 27:43.

—The wood of this species is hard and white, with radiating stripes. Intro. into S. Calif.

WILHELM MILLER.

F. TRACY HUBBARD.†

RHODÓSPATHA (Greek, *rose* and *spathe*, referring to the color of the spathe in some species). *Araceæ*. Climbing shrubs suitable for the warmhouse: branches often rooting: lvs. distichous, elliptic-oblong, acuminate: spathe cymbiform, beaked and deciduous; spadix shorter than the spathe, cylindrical, densely fld., the fls. all perfect or the lower pistillate; perianth none, stamens 4: berries small, oblong, truncate, 2-celled, many-seeded.—About a score species, Trop. Amer. See Engler, Pflanzenreich, IV. 23B.

Forgéti, N. E. Br. St. climbing: lvs. spreading; blade oblong-lanceolate, 16–20 in. long; the petiole about 12 in. long; peduncle 6 in. long; the spathe broadly elliptic, 6 in. long, a dirty pale rose-white outside and dirty rose inside. Costa Rica.

pictum, Nichols. (*Spathiphyllum pictum*, Hort. Lind.). Lvs. somewhat fleshy, broadly ovate-elliptic, 1½ ft. or more long, glossy dark green, mottled along the transverse veins with blotches of golden green. S. Amer.

RHODOSPHERA (Greek, *red* and *globe*; referring to the reddish globose fr.). *Anacardiaceæ*. A tree from Austral., closely related to *Rhus* but differing chiefly in the 10 stamens and in the very short free radicle of the embryo: lvs. odd-pinnate, subcoriaceous: fls. polygamo-dioecious, in terminal and axillary panicles, red; stamens 10; styles 3, free: fr. a globose drupe. In its native country the wood is esteemed for cabinet-work and used as a yellow dye and therefore called "yellow-wood." It is also a handsome foliage tree and is cult. in Calif. The only species is *R. rhodanthema*, Engl. (*Rhus rhodanthema*, F. Muell.). Evergreen tree to 60 or 70 ft., glabrous: lfts. 7–9, short-stalked, oblong-ovate, obtusely short-acuminate, dark green and lustrous above, lighter beneath, with tufts of hairs in the axils of the veins, 2–2½ in. long; panicles to 4 in. long; fls. small, ½ in. across, crimson or pink: fr. globose, reddish brown, ½ in. across. Queensland and New S. Wales. Maiden, Forest Fl. New S. Wales. 1:32.

ALFRED REHDER.

RHODÓSTACHYS (Greek, *rose* and *flower-spike*, alluding to the rose-colored fls. of some species). *Bromeliaceæ*. Herbs suitable for the warmhouse: lvs. rosulate, long, linear, rather stiff and spinulose-serrate: heads terminal, sessile within an involucre of numerous floral lvs.; fls. subsessile on a hemispherical or short-conical receptacle; sepals erect and strongly imbricated; petals free, imbricated; stamens free; ovary inferior. About 6 or 7 species, S. Amer. *R. andina*, Phil., is a low subcaulescent plant: lvs. linear, about 1 ft. long and 1 in. broad, aculeate-margined, glabrous: spike almost globose with scarious bracts about equaling the fls.; fls. rose; calyx-lobe lanceolate, strongly acuminate; petals nearly 1 in. long, linear-lanceolate, strongly acuminate. Chile. B.M. 7148. G.W. 3, p. 286. *R. pitcairniifolia*, Benth. & Hook. f. (*Fascicularia pitcairniifolia*, Mez). Sts. short, with some short branches at the top: lvs. many, crowded, ensiform from an ovate triangular base, about 1 ft. long and 1 in. wide, margins with short antrorse spines; the innermost lvs. bright red at their base: fls. in a dense central, sessile head, about 2 in. diam.; sepals narrowly lanceolate-acuminate; petals blue, oblong, obtuse, erect; ovary oblong, plano-convex. Chile. B.M. 8087.

F. TRACY HUBBARD.

RHODÓSTOMA (Greek, *rose* and *mouth*). *Rubiaceæ*. Closely allied to *Psychotria*. *R. gardenioides*, Scheidw., a plant 2 ft. high, with opposite obovate-lanceolate dark green lvs. and white fls. in terminal cymes, from S. Amer., has previously been sparingly in cult. H.U. 6, p. 225.—A warmhouse plant. The genus *Rhodo-*

stoma is now referred to *Palicourea* and this species becomes *P. gardenioides*, Benth. & Hook.

RHODOTHÁMNUS (Greek, *rhodon*, rose, and *thamnos*, shrub; alluding to the rose-colored fls.). *Ericaceæ*. Dwarf evergreen shrub, with alternate small entire lvs. and rather large pink fls., usually solitary at the ends of the branchlets. Related to *Kalmia*, but anthers not in pouches: lvs. alternate: sepals 5, half as long as corolla; corolla rotate, deeply 5-lobed; stamens 10, slightly longer than corolla: fr. a 5-celled, many-seeded dehiscent caps. Charming little alpine shrub, hardy N., but somewhat difficult to cult. It thrives best in peaty porous soil of constant, moderate moisture in a partly shaded situation, and is best suited for rockeries. Prop. by seeds or layers, also by cuttings of ripened wood under glass. The only species is *R. Chamæcistus*, Reichb. (*Rhododendron Chamæcistus*, Linn. *Adodendron Chamæcistus*, Kuntze). Diffusely branched shrub, to 1 ft.: lvs. cuneate-oblong, acute, setosely ciliate, ¼–½ in. long: fls. on slender, glandular-hirsute pedicels, solitary, rarely 2 or 3 at the end of the branchlets, light purplish pink, to 1 in. across. May. Alps of E. Eu. B.M. 488. L.B.C. 15:1491. P.M. 3:169. F.S. 19:1962. F.W. 1873:321. G.C. III. 33:293. ALFRED REHDER.

RHODOTÏPOS (Greek, *rhodon*, rose, and *typos*, type; alluding to the resemblance of the flowers to those of a single rose). *Rosaceæ*. Ornamental shrub, grown

chiefly for its large white flowers and for the handsome bright green foliage.

Leaves deciduous, opposite, stipulate, short-petioled, serrate: fls. solitary, short - pedicelled; sepals large, half as long as petals, outside with 4 small alternate bracts; petals 4, orbicular; stamens numerous; carpels usually 4, developing into black dry 1-seeded drupes, surrounded by the large persistent calyx.—One species in Japan. A handsome and distinct shrub, hardy as far north as Mass., with bright green foliage, conspicuous by its white fls. in spring and by its shining black fr. in autumn

3394. *Rhodotypos kerrioides*. (×½)

and winter. It thrives well in any good soil. Prop. by seeds and by greenwood cuttings under glass early in summer; also by hardwood cuttings.

kerrioides, Sieb. & Zucc. (*R. tetrapetala*, Makino). Fig. 3394. Much-branched, spreading shrub, usually 3–6 ft. high (in Japan 15 ft.): lvs. ovate to ovate-oblong, acuminate, sharply and doubly serrate, silky-pubescent beneath when young, 1½–3 in. long: fls. pure white, ½ in. across. May, June. S.Z. 1:99. B.M. 5805. L.I. 14. Gt. 15:505. R.H. 1866, p. 430. Gn. 6, p. 229; 34, p. 159; 43, p. 138. G. 7:18; 10:615.

ALFRED REHDER.

RHËO (name unexplained). *Commelinaceæ*. One species, from Mex. and the W. Indies, *R. discolor*, Hance, known also as *Tradescantia discolor*, L'Her.,

T. spathacea, Swartz, and *Ephemerum bicolor*, Moench. B.M. 1192. G.W. 15, p. 230. From *Tradescantia* the genus is distinguished by having 1 ovule (rather than 2) in each locule of the ovary. *R. discolor* is a short-stemmed erect-growing long-lyd. plant, not unlike a broad-lyd. small pandanus in habit. Fls. white, small, and many in a boat-shaped spathe-like structure arising from the axil of the lf. and which is sessile or nearly so; sepals 3, free, more or less petal-like; petals 3, soon withering; stamens 6. Var. *vittata*, Hook. (*Tradescantia discolor* var. *vittata*, Miq. *T. discolor* var. *variegata*, Hook. *T. variegata*, Hort.), is the common form in cult. The lvs. are 8–12 in. long, dark purple beneath and longitudinally striped above with pale yellow. A striking plant for the warmhouse, or for the open in the S. B.M. 5079. F.S. 11:1169, 1170. Cult. as for warmhouse tradescantias.

L. H. B.

RHOPALA: *Roupala*.

RHOPALOBASTE (Greek, *club* or *pestle*, and *em-bryo*). *Palmaceæ*, tribe *Arécæ*. A small group of Old World tropical palms of little horticultural significance: sts. simple, unarmed, crowned at the top by a large cluster of equally pinnatisect lvs.: lf.-segms. acuminate, 1-nerved: spadix appearing from among the lvs., much branched; stamens 6: fr. ellipsoid, red. Cult. as in chrysalidocarpus.

hexáandra, Scheff. St. about 4 ft., crowned by numerous lvs. which are much divided into lanceolate lflets.: spadix about 1½ ft. long, or in wild specimens longer, crowded with very small fls. Molucca and neighboring islands.—A little-known palm offered in Eu. but doubtfully cult. in Amer. outside of botanic gardens.

N. TAYLOR.

RHOPALÓSTYLIS (name refers to the club-shaped spadix). *Palmaceæ*, tribe *Arécæ*. Two species of pinnate palms, both of which are useful conservatory plants and nearly always sold as species of *Areca* or *Kentia*.

Spineless palms with medium ringed caudices: lvs. terminal, equally pinnatisect; segms. equidistant, numerous, narrowly sword-shaped, acuminate, the margins not thickened, recurved at the base, the midveins prominent, with 1–3 nerves on each side; rachis concave above, scurfy; petiole very short; sheath elongated: spadices short, spreading, with a very short thick peduncle, and fringed, rather thick, densely-fld. branches: spathes 2, symmetrical, oblong, flattened, the lower 2-winged: bracts adnate to the flower-bearing areas, subulate at the apex; bractlets scaly: fls. medium: fr. small or medium, ellipsoidal, smooth. *Rhopalostylis* belongs to the large group in which the ovule is borne on the side and is more or less pendulous, while in *Areca* and *Kentia* the ovule is at the base and erect. From the 5 cult. genera listed under *Hedyscepe* (which see) *Rhopalostylis* differs as follows: sepals of staminate fls. awl-shaped to lanceolate, not imbricated; stamens 6–12; pistillate fls. with short petals, valvate at the apex. Cult. as in *kentia*. Prop. by imported seeds under glass, over bottom heat. Hardy in S. Calif. if planted in shaded positions. Shade is necessary for thrifty growth as the fronds burn badly in the sun; and it will also furnish sufficient protection from frost.

sápida, H. Wendl. & Drude (*Areca sávida*, Soland. *Kéntia sávida*, Mast.). **NIKAU PALM**. St. 6–30 ft. high, 6–9 in. diam., cylindrical, green or often a pale glaucous green: lvs. 4–6 ft. long, pinnate; segms. very narrow, linear; margin replicate; nerves, midrib, and petiole covered with minute scales: spadix 18–24 in. long, half inclosed in the spathe, much branched; fls. pale pinkish: fr. an ovoid drupe, brown. New Zeal. B.M. 5139.

Baüeri, H. Wendl. & Drude (*Arèca Baüeri*, Hook. *Kéntia Baüeri*, Seem. *Seafórtia robústa*, Hort.). Stoutier and taller than *R. sávida*: lvs. larger and

broader, rarely, if ever, glaucous; segms. linear-lanceolate, acuminate; nerves, midrib, and petiole sparsely scaly: spadix 1–2 ft. long scarcely inclosed by the spathe; fls. white: fr. more globose, scarlet! Norfolk Isl. and Kermadecs. I.H. 15:575. B.M. 5735.

JARED G. SMITH.
N. TAYLOR.†

RHUBARB. A garden vegetable, perennial, grown for the thick acid leaf-stalks which are used in spring for sauces and pies: *Rheum Rhaponticum*, which see, page 2927.

Rhubarb, known also as pie-plant, is a hardy plant and will withstand considerable neglect, yet, like most cultivated vegetables, it responds readily to proper care and good treatment. The large fleshy leaf-stems desired in culinary use are produced in part by the great store of plant-food held in reserve by the many big roots. Everything should be done to increase this supply of reserve food. Tillage and fertilizing, therefore, are fundamentals. In the choosing of a site a southern exposure is preferred, with sufficient slope to give good drainage. Plow the ground 6 to 8 inches deep, draw furrows 5 feet apart, set the plants 3 feet apart, with the buds 1 inch below the level of the ground. In home grounds, spade or trench the land deep, and set about 4 feet apart each way; or if in only one row or line with plenty of room on either side, the plants may go 3 feet or even as close as 2½ feet if they are well manured and often renewed. If the soil lacks in fertility, mix compost with the earth that is placed about the roots; never put fresh manure next to the roots. As soon after planting as possible, start the cultivator, and give a thorough stirring at intervals of six to eight days up to the middle or last of August. After the ground is frozen, cover the rows 3 to 4 inches deep with manure that is as free as possible from weed and grass seed. As early in the spring as the ground can be worked to advantage, start the cultivator and work the manure into the soil. Each alternate season the surface of the soil should have a good dressing of manure. For garden culture, a similar practice should be undertaken with the hoe or other hand tools.

In field culture, the third or fourth year after planting the hills should be divided. Remove the earth from one side of the hill and with a sharp spade cut through

3395. Stalks of forced rhubarb. The leaf-blades do not develop.

the crown, leaving three or four buds in the hill undisturbed. This work should be done in the fall or early in the spring. In garden culture, the beds should be similarly renewed, at least as often as every four or five years, but more pains may be taken in dividing the plants. The clumps of roots grow so large, and have so many eyes, that the stalks soon become more numerous than desirable, and run down in size. Take up the entire roots and cut them in pieces, leaving only one strong eye to the piece, and plant the pieces in a newly prepared bed (or even in the old one if properly enriched and prepared) 4 feet apart each way as before.

Seed-stems are produced freely the entire season. These should be promptly pulled up, unless seed is wanted. The growth of these stems and the production of seed tend to lessen the vitality of the plant and to reduce the yield.

Propagation of rhubarb is commonly by division of

the roots, and this is the only method by which a particular type can be increased. Propagation from seed, however, sometimes proves satisfactory, and always interesting as the seedlings vary greatly. The seed germinates easily, and if started early the plants become fairly large and strong the same season. The seedlings may be started in any good clean garden soil. Sow seed in early spring, in rows a foot apart and not over an inch deep. Thin the plants promptly to stand a few inches apart in the rows, and give the same thorough tillage allowed to other garden crops. In the following fall or spring take the seedlings up, and set them in the well-prepared permanent patch, not less than 4 feet apart each way, and till frequently the entire season. In spring of the next year the stalks may be pulled freely.

From ten to twenty good plants should supply the needs of the usual family, and probably with something to spare for the neighbors. Sometimes an early supply is secured by placing a bottomless barrel or box over the plant and piling warm horse-manure about it. If the barrel, keg, or box is not too broad, the petioles will make a straight upright growth and will be partially blanched and very tender. *Victoria* and *Linnaeus* are the leading varieties.

L. H. B.†

Forcing of rhubarb.

In the winter and early spring months, the forcing of rhubarb in the vicinity of many city markets is a profitable industry. The plant may be forced either in the field where the roots were grown or lifted and placed in hotbeds, under greenhouse benches or in cellars. The bulk of the rhubarb forced for market and sold during the winter months is grown in cheap structures placed over the plants in the field. These houses may be of the lean-to type, although they are more commonly even-span post and rafter construction, the roof being covered with hotbed sash which is not needed for other purposes at the time. The side walls are 4 to 5 feet high, made of rough boards and covered with cheap building-paper. The even-span houses are mostly 24 to 36 feet wide and the lean-to house half that width. Heat is usually applied in an overhead system, steam being the most popular, although late in the season the sun is depended upon to supply the required amount of heat. When forced in the field in limited quantities, coldframes are often used, the outside walls being well banked with hot manure and the surface of the ground within the frames covered with 3 to 6 inches of the same material.

Beds intended for early spring forcing should be thoroughly cultivated in the fall and an application made of high-grade commercial fertilizer of 800 to 1,000 pounds to the acre. When growth starts, a dressing of nitrate of soda at the rate of one-half pound to a crown should be given. In field forcing, the moisture of the soil is usually sufficient so that no water is applied. When it is the intention to use a field for forcing for several years, the plants are usually set 2 by 3 feet and the land fertilized heavily each spring with a compost, one made from cow- and hog-manure being preferred. The sash are placed upon the first houses as soon as the roots have been frozen, five to seven weeks being necessary to bring the plants to maturity.

In field forcing, the cost of production is often greatly reduced by growing spinach or dandelion between the

rows, the price obtained for these fillers usually being sufficient to pay labor and maintenance costs. The stalks are usually pulled twice, returning to the grower from \$1 to \$2 a sash, depending upon the season when placed upon the market.

Roots for forcing in the dark should be healthy and vigorous; the larger the roots the more satisfactory the results as a general rule. Crowns three to five years of age are mostly used, although satisfactory results are often obtained from one-year-old plants which have been

3396. House for the forcing of rhubarb, covered with movable sash.

grown on very rich land and have made an unchecked growth during the season. The roots should be dug early in the fall before the ground freezes and allowed to remain exposed to the weather until they are frozen solid when they should either be removed to a shed or covered with litter in the field to prevent alternate freezing and thawing. Thorough freezing is necessary, whatever the method of forcing, if the best results are to be obtained. With one-year roots very satisfactory results are sometimes secured if the roots are thoroughly dried before forcing. Anesthetics have been tried as a substitute for freezing but with unsatisfactory results. When used upon frozen roots they stimulate growth, resulting in the production of earlier and larger stalks with greater total weight of product. If the greatest benefit is to be derived from the anesthetic, it must be used in the early part of the resting-period. The most satisfactory results have been obtained by the use of 10 cubic centimeters of sulfuric ether to a cubic foot of space, exposing the roots to the fumes for forty-eight hours. Well-grown two-year-old roots seem to respond to this treatment in the most satisfactory way.

As soon as the roots are placed in position, whether it be under the greenhouse benches or in the cellar, all spaces should be filled with soil or ashes to prevent evaporation. If placed on a concrete floor, 2 or 3 inches of soil should be placed under the roots and sufficient material should be added completely to cover the roots. The bed as soon as completed should be thoroughly watered, the plants kept supplied with an abundance of moisture, which will necessitate water being applied about once a week. Care should be taken to guard against over-watering as this will result in the production of light-colored stalks, lacking in flavor and texture. In order to obtain the most attractive product, rhubarb should not be forced in full light or total darkness. If grown in diffused light, the development of the leaf-blade is very slight and the color of the stalk, instead of being green, is a beautiful dark cherry-red, giving to the product a very attractive appearance. In quality the product is superior to that forced in light, being more tender, less acid, with a skin so thin and tender as to make it unnecessary to peel the stalks. The temperature may range from 45° to 75°, the lower the temperature the greater the yield and higher the quality of the product. The time required for bringing a crop to maturity in darkness is practically the same as that required for forcing in the field.

Local market demands to a certain extent govern the method which is used in growing this crop for the winter market. When grown by any method which

requires the lifting of the roots, it must be remembered that they are worthless after having produced a crop. Therefore, this method cannot be practised with as great profit upon expensive land as can the method of field forcing or when roots were used for forcing which otherwise would be destroyed. Rhubarb-forcing in house cellars should receive more attention, as it adds at slight expense a pleasing vegetable to the winter dietary.

Whatever the method practised, success will be attained only when healthy well-developed roots, which have been allowed to freeze, are used. G. E. ADAMS.

RHŪS (ancient Greek name). *Anacardiaceæ*. **SUMAC**. Ornamental woody plants, grown chiefly for their handsome foliage, often assuming brilliant autumnal colors, and some species also for their showy fruiting panicles. See also *Cotinus*.

Deciduous or evergreen shrubs, sometimes climbing by aerial rootlets, or trees, with milky or resinous juice: lvs. alternate, without stipules, simple, 3-foliate or odd-pinnate: fls. dioecious or polygamous, small, in axillary or terminal panicles; calyx 5-parted; petals 5, imbricate; stamens 5, inserted below a broad disk; ovary superior, with 3 styles: fr. a small 1-seeded dry drupe, smooth or hairy.—About 150 species in the temperate and subtropical regions of both hemispheres. Foliage and bark of most species are rich in tannin and are used for tanning leather, particularly the lvs. of *R. coriaria* in S. Eu. From *R. verniciflua* lacquer is obtained in China and Japan, used in the manufacture of lacquer-ware; *R. succedanea* yields a vegetable wax, used for candles in Japan, and also exported for various purposes. *R. lævigata* and some other S. African species are valued for their timber.

The sumacs are shrubs or trees with handsome simple or usually compound foliage assuming in most deciduous species brilliant autumnal colors, and with small comparatively inconspicuous flowers in usually large panicles, followed by small fruits which are deep red and showy in many species. The only species with rather showy flowers of creamy white color appearing in late summer is *R. javanica*, while *R. typhina*, *R. glabra*, and *R. copallina* are chiefly valued for their large pinnate leaves coloring scarlet in autumn and also for the conspicuous panicles of deep red fruits remaining almost unchanged on the plants during the winter; they are well adapted for mass-planting on barren ground and dry hillsides. Also *R. verniciflua*, *R. succedanea*, and *R. vernix* have handsome large foliage, but are poisonous like *R. Toxicodendron*, and for this reason are not recommended for extensive planting. The deciduous native species are hardy North, and *R. verniciflua*, *R. Potaninii*, *R. punjabensis* var. *sinica*, *R. javanica*, *R. trichocarpa*, and *R. sylvestris* are hardy as far north as Massachusetts, while *R. coriaria* is tender, and the evergreen species can be grown only in warmer temperate regions. Most species grow well in dry and barren soil, only *R. vernix* is a swamp-loving plant. Many species, particularly *R. Toxicodendron*, *R. glabra*, *R. typhina*, and *R. copallina*, spread by suckers and may become a nuisance in lawns and mixed plantations. Propagation is by seeds sown in autumn or stratified; all species grow readily from root-cuttings; some species, as *R. canadensis*, may be increased by layers or cuttings of mature wood.

KEY TO THE SPECIES.

- A. *Foliage simple, evergreen.*
 - B. *Lvs. glabrous.*
 - C. *Fr. pubescent, red.*
 - D. *Length of lvs. 1-2 in., apex usually obtuse.*..... 1. *integrifolia*
 - DD. *Length of lvs. 2-3 in., apex acute*..... 2. *ovata*
 - CC. *Fr. glabrous, whitish*..... 3. *laurina*
 - BB. *Lvs. pubescent.*..... 4. *mollis*
- AA. *Foliage compound.*
 - B. *Lfts. 3.*
 - C. *Plant evergreen.*
 - D. *Petiole slender, terete.*..... 5. *lævigata*
 - DD. *Petiole short, winged.*..... 6. *lucida*
 - CC. *Plant deciduous.*
 - D. *Fls. in dense catkin-like racemes: fr. hairy, red.*
 - E. *Lfts. glabrate, ½-1 in. long, with few rounded teeth.*..... 7. *trilobata*
 - EE. *Lfts. pubescent, 1-3 in. long, crenate-serrate.*..... 8. *canadensis*
 - DD. *Fls. in loose panicles: fr. glabrous, whitish.*
 - E. *Apex of lfts. obtuse, margin crenate.*..... 9. *diversiloba*
 - EE. *Apex of lfts. acute, margin entire or serrate.*..... 10. *Toxicodendron*
 - BB. *Lfts. 5 or more.*
 - C. *Infl. axillary: fr. glabrous, whitish: lfts. entire; lvs. crowded at the end of the branches.*
 - D. *Under side of lfts. more or less pubescent, at least while young, pale green; texture thin; pairs of veins usually 10-12.*
 - E. *Length of lfts. usually 2-4 in., base cuneate.*..... 11. *vernix*
 - EE. *Length of lfts. usually 4-6 in., base usually rounded.*..... 12. *verniceflua*
 - DD. *Under side of lfts. glabrous, grayish green, rarely green; texture firm; with usually 15-20 pairs of veins.*..... 13. *succedanea*
 - CC. *Infl. terminal: fr. hairy, red.*
 - D. *Fruiting panicles pendulous: lfts. entire, or sometimes serrate in young plants; rachis not or slightly winged.*
 - E. *Number of lfts. 5-7, rarely to 9; rachis terete.*..... 14. *Potaninii*
 - EE. *Number of lfts. 7-13; rachis narrowly winged in the upper part.*..... 15. *punjabensis*
 - DD. *Fruiting panicle upright: lfts. serrate except in No. 18.*
 - E. *Rachis winged.*
 - F. *Lfts. obtusish, rarely over 2 in. long.*..... 16. *coriaria*
 - FF. *Lfts. acute, over 2 in. long.*
 - G. *Margin of lfts. coarsely serrate, base usually rounded.*..... 17. *javanica*
 - GG. *Margin of lfts. entire or remotely serrate, base cuneate.*..... 18. *copallina*
 - EE. *Rachis terete, or in No. 19 often winged below the terminal lfts. only.*
 - F. *Lvs. densely brownish pubescent beneath: low shrub to 3 ft.*..... 19. *Michauxii*
 - FF. *Lvs. glabrous beneath or pubescent on the veins, glaucous.*
 - G. *Branchlets and infl. densely hairy.*..... 20. *typhina*
 - GG. *Branchlets glabrous, glaucous: infl. finely pubescent.*..... 21. *glabra*

1. *integrifolia*, Brew. & Wats. Shrub or small tree, occasionally to 30 ft.: lvs. short-stalked, oval, obtuse or sometimes acute, entire or spinosely toothed, glabrous, 1-2 in. long, very rarely 3-foliate: panicles hoary-pubescent, 1-3 in. long; fls. white or pinkish: fr. ovate,

flattened, $\frac{1}{2}$ in. long, dark red. Spring. Calif. S.S. 3:109.

2. *ovata*, Wats. Shrub, to 10 ft.: lvs. short-stalked, ovate, acute or acuminate, entire or rarely spinosely toothed, 2-3 in. long: fls. in dense spikes $\frac{1}{2}$ in. long, sometimes crowded into terminal panicles, light yellow: fr. ovate, flattened, dark red, $\frac{1}{4}$ in. long. Spring. S. Calif., Ariz.

3. *laurina*, Nutt. (*Lithræa laurina*, Walp.). Aromatic, glabrous shrub: branchlets purplish: lvs. oblong-ovate to lanceolate, acute and mucronulate, rounded at the base, entire, 2-3 in. long; petioles $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. in dense panicles, to 4 in. long, greenish white: fr. ovoid, beaked, $\frac{1}{2}$ in. long, whitish, with a waxy covering. Summer. S. and Low. Calif. —Will thrive in the hottest and driest places; very handsome with its dark green glossy foliage.

4. *mollis*, HBK. Tall shrub: branchlets tomentose: lvs. oval or ovate, rounded and mucronate at the apex, rounded or subcordate at the base, pubescent above, more densely so beneath, $1\frac{1}{2}$ - $2\frac{1}{2}$ in. long; petiole very short: fls. in dense pubescent panicles, about 1 in. long: fr. subglobose, pilose. Mex.

5. *lævigata*, Linn. Glabrous shrub or tree: petiole 2-3 in. long; lfts. sessile or short-stalked, ovate, acuminate, cuneate at the base, entire or sometimes with 2-6 teeth, lustrous above, 2-3 in. long: panicles loose, axillary and terminal; fls. minute, whitish, slender-pedicelled: fr. globose, glabrous, lustrous, about $\frac{1}{4}$ in. across. S. Afr. Sim, For. Fl. Cape Colony 45.

6. *lucida*, Linn. Glabrous shrub, to 6 ft.: branchlets sometimes puberulous: petiole $\frac{1}{4}$ - $\frac{1}{2}$ in. long, narrowly winged; lfts. sessile, obovate, obtuse or emarginate, entire, rarely slightly toothed, lustrous, distinctly veined, 1- $2\frac{1}{2}$ in. long: panicles terminal and axillary, about as long as lvs.: fr. globose, glabrous, about $\frac{1}{4}$ in. across. S. Afr.

7. *trilobata*, Nutt. (*Schmaltzia trilobata*, Small). SKUNK-BUSH. ILL-SCENTED SUMAC. Offensive-scented shrub, to 3, rarely to 6 ft. high: lvs. petioled, 1-2 in. long; lfts. sessile or nearly so, oval or obovate, obtuse, crenately toothed, puberulous while young, soon glabrous, the terminal one usually 3-lobed: fls. greenish, in clustered spikes before the lvs.: fr. subglobose, red, hairy, $\frac{1}{4}$ in. across. Mo. to Wash., Calif., and Texas. B.B. (ed. 2) 2:483.

8. *canadensis*, Marsh. (*Schmaltzia aromatica*, Desv. *R. aromatica*, Ait. *Schmaltzia crenata*, Greene). Aromatic shrub, to 3 ft., with ascending or diffuse branches: lvs. petioled, 2-4 in. long; lfts. pubescent, the terminal one ovate or obovate, acute or acuminate, cuneate at the base; the lateral lfts. ovate, unequal at the base: fls. and frs. like those of the preceding species, but fls. yellow and frs. slightly larger. Ont. and Vt. to Minn. and south to Fla. and La.—A good cover plant for dry rocky banks; conspicuous in early spring by its yellow fls. B.B. (ed. 2) 2:482.

9. *diversiloba*, Torr. & Gray. POISON OAK. Upright shrub or sometimes climbing by rootlets: branchlets pubescent: lfts. ovate, elliptic or obovate, usually obtuse, coarsely crenate-serrate or 3-lobed, sparingly

pubescent while young, 1-3 in. long: fls. yellowish green, in peduncled panicles: fr. white, $\frac{1}{2}$ - $\frac{1}{4}$ in. across, falling soon after maturity. Brit. Col. to Calif.—Poisonous like the following and not to be recommended for planting.

10. *Toxicodendron*, Linn. (*Toxicodendrum vulgare*, Mill. *R. radicans*, Linn. *R. Toxicodendron* var. *radicans*, Torr.). POISON IVY. POISON OAK. Fig. 3088, p. 2728. Suberect and scrambling over walls and fences or high-climbing by aerial rootlets: lfts. ovate or rhombic, acute or short-acuminate, entire or sparingly dentate or sinuate, more or less pubescent beneath, 1-6 in. long: fls. greenish, in loose axillary panicles 1-3 in. long: fr. whitish, subglobose, $\frac{1}{2}$ in. across, remaining on the plant during the winter. Spring. Nova Scotia to Fla. west to Minn., Neb., and Ark. Em. 577.—It colors beautifully scarlet and orange in autumn, but is very poisonous to many and therefore should not be planted

near places where persons are likely to come in contact with it; in such places it should rather be extirpated. It is, however, very difficult to eradicate, for it spreads by suckers and each piece of root left in the ground sprouts again.—The plant described above is

by some called *R. radicans*, Linn., and the name *Toxicodendron* is restricted to an upright shrubby form with pubescent crenate or crenately lobed lvs., native to the S. Atlantic states, also called *R. quercifolia*, Steud.; also several

3397. *Rhus javanica*. ($\times \frac{1}{4}$)

other closely related species have been distinguished.

11. *vernix*, Linn. (*R. venenata*, DC.). POISON SUMAC. POISON ELDER. Fig. 3089, p. 2728. Shrub or tree, to 20 ft.: lfts. 7-13, oval to oblong, acuminate, cuneate at base, undulate, glabrous or slightly pubescent beneath usually 2-4 in. long: fls. greenish, in loose axillary panicles 3-8 in. long: fr. subglobose, gray, flattened, $\frac{1}{2}$ in. across. Swamps, R. I., Ont., and Minn., south to Fla. and La. S.S. 3:107, 108. Em. 575.—Very poisonous: foliage turns to a brilliant scarlet in autumn.

12. *verniciiflua*, Stokes (*R. verniciifera*, DC. *R. vernix*, Thunb.). VARNISH-TREE. LACQUER TREE. Tree, to 60 ft.: lfts. usually 11-15, short-stalked, ovate-oblong to oblong-lanceolate, acuminate, rounded or broadly cuneate at the base, entire, more or less pubescent beneath while young, 3-6 in. long: fls. whitish, in slender axillary panicles about half as long as the lvs.: fr. broader than long, compressed, straw-yellow, smooth, $\frac{1}{4}$ in. broad. May. Japan, China, Himalayas. S.I.F. 1:57. I.T. 6:201. Gn. 34, p. 158.—From this tree the lacquer used for the highly polished woodenware is obtained in Japan and China; the fr. yields a fatty oil. The tree is poisonous like the preceding species.

13. *succedanea*, Linn. WAX-TREE. Shrub or small tree, to 30 ft.: lfts. 9-15, short-stalked, elliptic-oblong to oblong-lanceolate, long-acuminate, broadly cuneate at the base, entire, lustrous above, usually grayish green or glaucous beneath, quite glabrous, usually with 15-20 pairs of veins prominent beneath, 2-4 in. long: fls. yellow-green, in axillary slender panicles: fr. broader than high, compressed, whitish, $\frac{1}{3}$ - $\frac{1}{4}$ in. broad. May.

Japan, China, Himalayas. S.I.F. 1:57. R.H. 1863, p. 130.—From the fr. of this tree a wax-like substance chiefly used for making candles is expressed in Japan. The tree is poisonous.

14. *Potanfnii*, Maxim. (*R. sinica*, Koehne, not Diels). Shrub or tree, to 25 ft.: branchlets minutely puberulous: rachis terete or sometimes slightly winged between the

3398. *Rhus typhina*.—Staghorn sumac.

upper lfts.; lfts. 5-7, short-stalked, ovate or elliptic-ovate, acuminate, rounded or broadly cuneate at the base, entire, on young plants usually coarsely toothed, pubescent beneath on the veins, 2-4 in. long: fls. whitish, in terminal panicles: fr. dark red, densely hairy, in pendulous panicles to 5 in. long. May, June. Cent. and W. China. M.D. 1910, p. 103, and G.M. 51:419; 52:721 (as *R. sinica*).

15. *punjabensis*, Stew. Tree, to 40 ft.: branchlets short-pubescent: lfts. short-stalked, oblong or ovate-oblong, acuminate, rounded or subcordate at the base, slightly pubescent beneath, at least on the veins, entire, 3-5 in. long: fls. whitish, in broadly pyramidal panicle with spreading branches: fr. suborbicular, red, tomentose, $\frac{1}{6}$ - $\frac{1}{5}$ in. broad. Himalayas. Var. *sinica*, Rehd. & Wilson (*R. sinica*, Diels). Upper part of the rachis narrowly winged; lfts. 7-11, on young plants sometimes 17 and wings more pronounced and often continuing down the whole length of the rachis: fruiting panicle 5-8 in. long and 4-6 in. broad. June, July; fr. in Sept. Cent. and W. China.—This and the preceding species are strong-growing plants with handsome foliage; very attractive in autumn with their large pendulous panicles of dark red fr.

16. *coriaria*, Linn. Shrub, to 20 ft.: petiole short; rachis winged, at least in the upper part, villous; lfts. 9-15, oval to oblong, obtuse or acutish, coarsely toothed, pubescent beneath, $1\frac{1}{2}$ -2 in. long: fls. greenish, in a rather loose terminal panicle: fr. crimson, densely pubescent. July. Medit. region, W. Asia. H.W. 3, p. 33.—The lvs. are used for tanning leather.

17. *javanica*, Linn. (*R. semialata*, Murr. *R. Osbeckii*, Deene. *R. semialata* var. *Osbeckii*, DC.). Fig. 3397. Shrub or flat-headed tree, to 25 ft.: rachis and often the petiole winged, pubescent; lfts. 7-13, short-stalked or nearly sessile, ovate to ovate-oblong, acute or short-acuminate, rounded or broadly cuneate at the base, coarsely crenate-serrate, brownish pubescent beneath, 2-6 in. long: fls. creamy white, in large and broad panicles, to 12 in. long: fr. subglobose, compressed, red, densely pubescent. Aug., Sept.; fr. in Oct. Japan, China, S. Asia. S.I.F. 1:58. G.W. 1:99. M.D.G. 1899:166.—Valuable for its late blooming season and the most showy of the sumacs in bloom. Var. *Roxburghii*, Rehd. & Wilson (*R. semialata* var. *Roxburghii*, DC.). Rachis not or very slightly winged. Himalayas.—Tender, rarely cult.

18. *copallina*, Linn. (*Schmaltzia copallina*, Small). BLACK SUMAC. MOUNTAIN or SHINING SUMAC. Shrub

or tree, occasionally to 30 ft.: rachis winged, pubescent; lfts. 9-21, oblong-ovate to oblong-lanceolate, entire or few-toothed toward the apex, glabrous and lustrous above, usually pubescent beneath, $1\frac{1}{2}$ -4 in. long: fls. greenish, in dense terminal panicles: fr. compressed, hairy, crimson. July, Aug.: fr. Sept., Oct. Maine and Ont. to Minn., south to Fla and Texas. S.S. 3:104, 105. Var. *lanceolata*, Gray. Lvs. narrowly lanceolate, often falcate. Texas. S.S. 3:106.—Succeeds well in dry soil; handsome with its dark green glossy foliage.

19. *Michauxii*, Sarg. (*R. pumila*, Michx. *Schmaltzia Michauxii*, Small). Low shrub with decumbent sts. about 1 ft. high, densely pubescent: lfts. 9-15, oval to oblong-ovate, acuminate, coarsely serrate, 2-4 in. long: fls. greenish, in panicles 4-8 in. long: fr. compressed, deep red, pubescent. Spring. N. C. to Ga. G.F. 8:405.—Poisonous.

20. *typhina*, Linn. (*R. hirta*, Sudw. *Schmaltzia hirta*, Small). STAGHORN SUMAC. Fig. 3398. Shrub or tree, to 30 ft.: branchlets densely velvety-hairy: lfts. 11-31, oblong-lanceolate, pointed, serrate, glaucescent beneath, 2-5 in. long: fls. greenish, in dense terminal panicles: fr. crimson, hairy. June, July; fr. Aug., Sept. Em. 571. S.S. 3:102, 103. Gn. 54, p. 505. G.F. 2:343 (adapted in Fig. 3398). Que. to Ont., south to Ga., Ind., and Iowa. Var. *laciniata*, Wood. Lfts. and bracts deeply and laciniately toothed and the infl. sometimes partly transformed into contorted bracts. Var. *dissecta*, Rehd. (var. *laciniata* Hort.). Fig. 3399. Lfts. pinnately dissected. M.D.G. 1900:211. G.M. 53:827. R.H. 1907, pp. 10, 11. A very handsome form with finely cut foliage. *R. typhina filicina*, Sprenger, is probably not different.—The staghorn sumac grows in the driest soils and is a very desirable plant on account of its brilliant fall coloring, which in dry localities begins to show in Aug., and with its crimson fr.-clusters persisting through the winter. Trained in tree form it is very picturesque, but is short-lived.

21. *glabra*, Linn. (*Schmaltzia glabra*, Small). SMOOTH SUMAC. Fig. 3400. Shrub, to 15 ft. with glabrous and glaucous branches: lfts. 11-31, lanceolate-oblong, pointed, serrate, glaucous beneath, 2-5 in. long: fls. green, in dense panicles, to 10 in. long: fr. scarlet, viscid-pubescent. July; fr. in Aug., Sept. Em. 572. G.W. 3, p. 145. F.E. 30:681. Var. *laciniata*, Carr. Lfts. pinnately dissected. F.E. 31:875. G. 1:533. R.H. 1863, p. 7. V. 10:101. This variety with its deeply and finely cut lvs. is very handsome; it is tender than the cut-lyd. form of the preceding species and does not grow so high.

R. cotinoides, Nutt. = *Cotinus americana*.—*R. Cotinus*, Linn. = *Cotinus Coggrygia*.—*R. Delavayi*, Franch. Allied to *R. succedanea*. Glabrous shrub: lfts. 5-7, elliptic, 1-2 in. long, light green beneath:

3399. Young plants of *Rhus typhina* var. *dissecta*.

infl. 2-3½ in. long. W. China. Var. *quinquejuga*, Rehd. & Wilson. Lfts. 5-11, slightly pubescent while young. W. China.—*R. hybrida*, Rehd. Hybrid between *R. glabra* and *R. typhina*, found occasionally among the parents: young branchlets sparingly or densely pubescent; lfts. on the veins beneath slightly pubescent; hairs of the fr. exactly intermediate in length between those of the parents.—*R. orientalis*, Schneid. (*R. Toxicodendron* var. *hispida*, Engl.). Allied to *R. Toxicodendron*. Climbing; young branchlets hairy; lfts. dull green above, entire; fr. pilose. Japan, China.—*R. rhodanthema*, F. Muell. = *Rhodosphera rhodanthema*.—*R. sylvestris*, Sieb. & Zucc. Allied to *R. succedanea*. Shrub or tree, to 30 ft.: young branchlets, rachis, and lfts. beneath pubescent. Japan, China. S.I.F. 1:58.—*R. tomentosa*, Linn. Allied to *R. laevigata*. Shrub or small tree: lfts. 3, oblong, entire or crenate-dentate,

3400. *Rhus glabra*. (×½)

tomentose beneath, 1½-3 in. long. S. Afr. I.T. 3:111.—*R. trichocarpa*, Miq. Allied to *R. verniciflua*. Shrub or small tree: petiole and lfts. beneath pubescent; lfts. usually smaller; panicle shorter and denser: fr. pilose. Japan, China. ALFRED REHDER.

RHYNCHÁNTHUS (Greek, *beak and flower*, referring to the peculiar shape of the fls.). *Zingiberaceæ*. Slender glabrous perennial herbs with tuberous roots, suitable for the warmhouse: sts. erect, leafy, the lvs. sessile; fls. sessile, borne in a terminal, few-fl. spike; bracts solitary, elongate, and colored; calyx tubular, cylindrical; corolla funnel-shaped, the lobes ovate-lanceolate, acuminate, and erect; ovary 3-celled.—About 3 or 4 species, Burma. *R. Bluthianus*, Wittm. Sts. up to 1 ft. high, not thickened at the roots: lvs. 4, oblong-lanceolate, sessile, acuminate, not marginate: fls. 2, up to 2 in. long; calyx beautiful red, truncate, 3-toothed; corolla red; ovary smooth. Burma. Gt. 48:1464. *R. Johnianus*, Schlecht. Tuberous: up to 4½ ft. high: lvs. distichous, lanceolate, acuminate, both sides glabrous: infl. many-fl., oblong, with bright red, lanceolate, acuminate bracts; fls. sulfur-yellow; calyx cylindrical, split, the apex 2-cleft; corolla 3-cleft to below the middle, the segms. lanceolate, acuminate; ovary cylindrical. Burma. Gt. 56:1560. *R. longifolius*, Hook. f. Sts. 1½ ft. high, thickened at the roots: lvs. 8-12, regularly distichous, 5-7 in. long, oblong-lanceolate, acuminate, red-margined: fls. 4-5, up to 3½ in. long; calyx slightly shorter than the bracts; corolla-tube pale yellow-green, lobes green; ovary puberulous. Burma. B.M. 6861. F. TRACY HUBBARD.

RHYNCHÒSIA (Greek, *beak*, alluding to the shape of the keel). *Leguminosæ*. Twining, prostrate, or rarely erect herbs, shrubs, or subshrubs, suitable for the warmhouse or outdoors in the southernmost parts of the United States.

Plants often glanduliferous, with minute yellow glands: lvs. pinnately, or rarely subdigitately, 3-divided; fls. yellow, mostly in axillary racemes; calyx unequally 3-cleft or 4-5-parted; standard rounded, often darkly lined, rarely purple; legume compressed continuous.—About 100 species in the warmer regions of both hemispheres. The name *Dolicholus* is sometimes used for this genus, but *Rhynchosia* is one of the names maintained by the "nomina conservanda" accepted by the Vienna Congress.

mínima, DC. Tomentose or glabrescent herb: st. about 1 ft. high, low, twining, obtuse-angled: lfts. ovate-rhomboid, rather acute: fls. racemose, distant; calyx-lobes lanceolate-linear, the inferior about half as long as corolla; legume not constricted, oblong, tapering at the base, pubescent; seeds black. Texas, Mex. to Brazil, W. Indies, Trop. Afr., and Asia.

phaseoloides, DC. Tomentose or glabrate, a high climber, subshrubby: st. twining and subcylindrical: lfts. ovate or ovate-rhomboid, pointed: racemes many-fl.; calyx-lobes ovate-lanceolate or ovate, pointed, the inferior half as long as the standard; legume constricted between both seeds, tomentose or glabrescent; seeds black, with a scarlet-yellow ring around the hilum. Panama to Brazil, W. Indies and Galapagos Isls.

F. TRACY HUBBARD.

RHYNCHOSPÉRMUM (Greek, *beak and seed*, referring to the form of the seed). *Apocynaceæ*. Now referred to *Trachelospermum*. *R. jasminoides*, Lindl. = *Trachelospermum jasminoides*, Lem., which see. There is, however, a good botanical genus named *Rhynchospermum*, but it belongs to the composite family. It has only one species, *R. verticillatum*, a plant not in cultivation.

RHYNCHÓSPORA: *Rhynchospora*.

RHYNCHÓSTYLIS (Greek, *beaked column or style*). *Orchidaceæ*. Epiphytic herbs closely related to *Saccolabium* and usually sold under that name.

Stems monopodial and 2-ranked: lvs. crowded, leathery or fleshy: fls. in dense racemes from the axils of the lvs., medium-sized; dorsal sepal and petals sub-similar, lateral sepals broader, decurrent on the foot of the column; labellum firmly joined to the base of the column, obovate, inflexed at the apex, not 3-lobed, spurred, the spur straight or curved backward. For cult., see *Saccolabium*.

retûsa, Blume (*Saccolabium guttatum*, Lindl. *S. præmorsum*, Lindl. *S. Rheedii*, Wight. *S. retisum*, Voigt. *S. Blumei*, Lindl.). St. stout, with channeled lvs. 6-20 in. long; fls. in dense, cylindrical racemes about as long as the lvs., ¾ in. across, white, blotched with pink or violet. June, July. Trop. India and Malay Isls. B.M. 4108. F.S. 7, p. 92; 14:1463, 1464. B.R. 1443 (as *Sarcanthus guttatus*). G.C. 1845:364; II. 1:219; 23:573; III. 15:812. Gn. 31, p. 537. A.G. 20:317. S.H. 2, p. 375.—Several varieties are in the trade. Var. *majus*, Hort. Larger in all its parts. I.H. 15:545. Gn. 31, p. 69; 36, p. 230 (all as *Saccolabium Blumei* var. *majus*). Var. *Holdfordiana*, Hort., an old form with large racemes of waxy white fls., spotted with crimson, the lip being also crimson. Var. *gigantæa*, Hort., very much like the type. Var. *alba*, Hort. Fls. entirely white. Var. *Dayi* and var. *superba* are offered.

violæcea, Reichb. f. (*Saccolabium violaceum*, Reichb. f.). Lvs. 10-12 in. long; racemes 1 ft. or more long; fls. 1 in. across, white, spotted with pale mauve; labellum dark violet. Jan. Philippines. B.R. 33:30 (as *Vanda*).—The blossoms are said to have a disagreeable odor. Var.

Harrisonianum, Hort. (*Saccolabium Harrisonianum*, Hook.). Lvs. distichous, oblong, obliquely bifid at the apex; raceme dense, cylindrical, pendulous; fls. white, fragrant; sepals ovate-oblong, somewhat incurved; petals narrower, oblong-spatulate; labellum oblong-obovate, with a thick blunt apiculus, saccate toward the apex; spur blunt; disk with a single thickened line. Malay Isls. B.M. 5433, F.S. 23:2412.—The racemes grow to a length of 2 ft.

cœlestis, Reichb. f. (*Saccolabium cœleste*, Reichb. f.). St. rather stout: lvs. 4-6 in. long, fleshy; peduncles erect, bearing a dense raceme: fls. crowded, $\frac{3}{4}$ in. across; sepals and petals similar, oval-oblong, obtuse, white with a blotch of indigo, at apex; lip obovate-oblong, white at base, bright indigo at apex. Siam.

HEINRICH HASSELBRING.
GEORGE V. NASH.†

RHYTIGLOSSA (Greek, *wrinkle and tongue*, the palate of the lower lip is wrinkled). *Acanthaceae*. A genus in which about 75 species have been described, now referred to *Dianthera*, which see.

RIBES (probably derived from *ribas*, the Arabic name for *Rheum Ribes*, or by some supposed to be the Latinized form of *riebs*, an old German word for currant). *Saxifragaceae*. CURRANT. GOOSEBERRY. Woody plants partly grown for their edible fruits and partly for their handsome flowers, fruits, or foliage.

Unarmed or prickly shrubs with deciduous or rarely evergreen foliage: lvs. alternate, often fascicled, simple, usually palmately lobed and mostly plaited in the bud: fls. perfect or in some species dioecious, 5-merous, rarely 4-merous, in many-fld. to few-fld. racemes, or solitary; calyx-tube cylindric to rotate, like the sepals usually colored; petals usually smaller than the sepals, often minute, rarely entirely wanting; stamens alternating with the petals, shorter or longer than the sepals; ovary inferior, 1-celled; styles 1 or 2 (Fig. 3401): fr. a many-seeded pulpy berry, crowned by the remains of the calyx. —About 150 species in the colder and temperate regions of N. and S. Amer., N. and Cent. Asia, Eu., and N. Afr. The genus is sometimes divided into two: the true *Ribes* with usually unarmed sts., racemose fls., and jointed pedicels, and *Grossularia* (p. 1414) with prickly sts.; fls. solitary or in short 2-4-fld. racemes and with the pedicels not jointed. The most recent monograph of the genus is by Janczewski, *Monographie des Groseilliers*, 1907 (originally published in *Mém. Soc. Phys. Nat. Hist. Genève*, 35:199-517, with 202 figs.), with important supplements in *Bull. Acad. Sci. Cracovic*, ser. B, 1910-13. The N. American species are treated by Coville & Britton in *North American Flora*, 22:193-225 (1908) under the two genera *Ribes* and *Grossularia*. There are also descriptions and figures of the more important species in Card's *Bush Fruits*, 444-84, figs. 80-109 (1911).

The currants and gooseberries are usually low, upright or less often procumbent deciduous, rarely evergreen shrubs with prickly or unarmed branches, small or medium-sized usually lobed leaves, with rather small solitary or racemose flowers often greenish or reddish and insignificant, but in some species white or brightly colored in shades of red, scarlet, orange or yellow; the fruits also are often attractive and either black, purple, scarlet, yellowish or greenish. The flowers appear in spring with the leaves, and the fruits ripen in June or July, but in *R. fasciculatum* they do not mature until September and remain on the branches all winter. Most species are hardy North except the evergreen ones; also *R. sanguineum*, *R. Roezlii*, *R.*

Lobbii, *R. viscosissimum* are not quite hardy North. The tender *R. speciosum* with fuchsia-like bright red flowers is perhaps the most showy species of the genus, though also *R. sanguineum*, *R. odoratum*, *R. Gordonianum*, *R. Roezlii*, *R. Lobbii*, *R. pinelorum*, *R. cereum*, *R. inebrians*, *R. niveum*, and others are handsome in bloom, while some, as *R. alpinum* and *R. fasciculatum*, have ornamental scarlet fruits. They are well adapted for borders of shrubberies and, particularly the procumbent kinds, for planting on slopes. *R. alpinum* is excellent for shady places and as undergrowth. *R. alpestre*, a strong-growing and very spiny gooseberry from western China, may prove valuable as a hedge-plant. Many species bear edible fruits; the most important are the domestic currant, *R. vulgare*, and the European gooseberry, *R. Grossularia*; of less importance are the black currant, *R. nigrum*, the Buffalo or Missouri currant, *R. odoratum*, the European *R. rubrum* and some of the American gooseberries, as *R. hirtellum*, *R. Cynosbati*, *R. oxyacanthoides*, *R. setosum*, *R. inerme*. These plants are mostly of easy cultivation; they grow in any moderately good loamy soil; the gooseberries preferring as a rule drier and sunnier positions, while the currants like more humidity and grow well in partly shaded situations. Propagation is by seeds which germinate readily; also by hardwood cuttings in autumn and by greenwood cuttings in summer under glass; mound-layering in summer is sometimes practised; budding or grafting is usually resorted to only, if quick propagation of rare varieties is desired. In Europe, currants and gooseberries are sometimes grafted high on *R. odoratum* trained to one stem, to form little standard trees. See also *Currant* and *Gooseberry* for cultivation.

KEY TO THE SPECIES.

- A. Branches unarmed (or 2 small prickles below the lf. in No. 19): fls. usually in racemes; pedicels not jointed.
- B. Fls. tubular, red, yellow or white.
- C. Color of fls. yellow; fls. glabrous: lvs. convolute in bud.

3401. Flower of garden currant, to show structure. (X 4)

- B. Calyx-tube about twice as long as sepals; sepals revolute or spreading. 1. *odoratum*
- DD. Calyx-tube 1-1½ times as long as sepals. 2. *aureum*
- CC. Color of fls. red or white; lvs. plaited in bud.
- D. The fls. red or red and yellow, rarely white.
- E. Lvs. glabrous or nearly so beneath; fls. pale yellow and red. 3. *Gordonianum*
- EE. Lvs. white-tomentose beneath; fls. red, rarely white. 4. *sanguineum*
- DD. The fls. white, pink, or greenish; lvs. glabrous or pubescent and green beneath.
- E. Plants glandular-viscid: raceme short.
- F. Fr. black; calyx-tube cylindric-campanulate; lvs. 2-3 in. broad. 5. *viscosissimum* [mum]
- FF. Fr. red; calyx-tube tubular; lvs. ½-1½ in. broad.
- G. Bracts of raceme cuneate-obovate, toothed; fls. white or whitish. 6. *cereum*
- GG. Bracts rhombic, usually acute; fls. pink. 7. *inebrians*
- EE. Plant not glandular-viscid; lvs. resinous-dotted beneath; racemes pendulous; fls. whitish; fr. black. 8. *americanum*
- BB. Fls. saucer-shaped or open-campanulate, greenish or whitish.
- C. Lvs. resinous-dotted beneath.
- D. Racemes nodding, short; fls. broadly campanulate; lvs. 3-5-lobed. 9. *nigrum*
- DD. Racemes upright, to 8 in. long; fls. rotate; lvs. 5-7-lobed. 10. *bracteosum*
- CC. Lvs. not resinous-dotted.
- D. Habit decumbent.
- E. Ovary and fr. glandular; racemes erect. 11. *glandulosum*
- EE. Ovary and fr. glabrous; racemes nodding. 12. *triste*
- DD. Habit upright.
- E. Racemes drooping, many-fl.; fls. perfect; petiole 1½-3 in. long.
- F. Calyx-tube broadly campanulate; fls. purple, pink, or reddish. 13. *petræum*
- FF. Calyx-tube saucer-shaped.
- G. Stamens as long as sepals; sepals reflexed. 14. *multiflorum*
- GG. Stamens shorter than sepals; sepals spreading.
- H. Disk of fl. with a big narrow ring; anther-cells separated by a broad connective; lvs. cordate or subcordate. 15. *vulgare*
- HH. Disk of fl. flat; anther-cells contiguous; lvs. usually truncate. 16. *rubrum*
- EE. Racemes upright; fls. dioecious, small, greenish; petiole about 1 in. long or less.
- F. Branches always unarmed; lvs. truncate to subcordate.
- G. Pistillate fls. in 2-4-fl. fascicles; lvs. subchartaceous. 17. *fasciculatum*
- GG. Pistillate fls. in dense racemes; lvs. thin. 18. *alpinum*
- FF. Branches with slender paired prickles, sometimes unarmed; lvs. usually cuneate at the base. 19. *diacantha*
- AA. Branches with prickles, rarely nearly unarmed; fls. 1-4 and pedicels jointed (except in No. 20).
- B. Fls. in racemes; sepals broader than long; sts. very bristly. 20. *lacustre*
- BB. Fls. 1-4; sepals longer than broad.
- C. Color of fls. white or greenish suffused with purple.
- D. Sepals white (or greenish white in No. 23).
- E. Stamens as long as sepals or longer.
- F. Filaments villous; branchlets brown.
- G. Ovary glabrous; calyx-tube about as broad as long. 21. *niveum*
- GG. Ovary glandular or pubescent; calyx-tube twice as broad as long. 22. *curvatum*
- FF. Filaments glabrous; stamens nearly twice as long as the greenish white sepals; branches yellowish. 23. *missouriense*
- EE. Stamens shorter than sepals; young branchlets usually very bristly.
- F. Peduncles scarcely exceeding the bud-scales; calyx-tube campanulate. 24. *oxyacanthoides* [thoides]
- FF. Peduncles elongated; calyx-tube cylindric-campanulate. 25. *setosum*
- DD. Sepals greenish, often tinged purplish.
- E. Lvs. cuneate or rounded at the base.
- F. Sepals about as long as tube; stamens as long, rarely longer than sepals. 26. *hirtellum*
- FF. Sepals about twice as long as tube; stamens slightly exceeding the sepals. 27. *rotundifolium*
- EE. Lvs. subcordate or occasionally rounded at the base.
- F. Petals spatulate or flabellate, less than half as long as sepals; style and calyx-tube inside pubescent.
- G. Fr. smooth or glandular-bristly.
- H. Ovary glabrous.
- I. Sepals longer than tube; stamens slightly longer than sepals. 28. *divaricatum*
- II. Sepals shorter than tube; stamens slightly shorter than sepals. 29. *inermis*
- HH. Ovary pubescent or glandular; stamens about half as long as sepals. 30. *Grossularia*
- GG. Fr. prickly, not glandular, rarely smooth; stamens less than half as long as sepals. 31. *Cynobati*
- FF. Petals elliptic, more than half as long as sepals; style and calyx-tube inside glabrous. 32. *alpestre*
- CC. Color of fls. orange, purple, or bright red.
- D. Fls. 5-merous.
- E. Stamens shorter than sepals; fr. prickly.
- F. Sepals glabrous outside, orange; anthers oval, yellow. 33. *pinetorum*
- FF. Sepals pubescent outside, purple; anthers sagittate, purple. 34. *Roetzlii*
- EE. Stamens longer than the purplish red sepals. 35. *Lobbii*
- DD. Fls. 4-merous, bright red; stamens 2-4 times as long as sepals. 36. *speciosum*

Section 1. RIBES. Currants.

1. *odoratum*, Wendl. (*R. longiflorum*, Nutt. *R. fragrans*, Lodd. *R. palmatum*, Thory. *R. aureum*, Auth., not Pursh. *R. missouriense*, Hort. *Chrysobötrya revoluta*, Spach). MISSOURI CURRANT. BUFFALO CURRANT. GOLDEN CURRANT. Fig. 3402. Shrub, to 6 ft.: young

3402. Yellow-flowering currant.—*Ribes odoratum*. ($\times \frac{1}{2}$)

branchlets pubescent: lvs. ovate to orbicular-reniform, cuneate or truncate at the base, deeply 3-5-lobed and coarsely dentate, glabrate, 1-3 in. broad; petioles pubescent, shorter than blade; racemes 5-8-fld.; rachis pubescent; bracts ovate to oval, foliaceous; fls. yellow, fragrant; tube about $\frac{1}{2}$ in. long, stout; sepals oblong, scarcely half as long as tube, spreading or revolute; petals nearly half as long as sepals, more or less red; fr. globose or ovoid, about $\frac{1}{2}$ in. across, black. East of Rocky Mts., S. D. to Texas, east to Minn. and Ark. L.B.C. 16:1533. B.R. 125. L.D. 5:301. H.F. 1872:225 (as *R. Oregoni*).—A handsome shrub with yellow fragrant fls. appearing early in spring with the lvs. A form with large berries nearly $\frac{3}{4}$ in. diam. is sometimes cult. for its frs. as the Crandall.

2. *aureum*, Pursh (*R. tenuiflorum*, Lindl. *R. jasminiflorum*, Agardh. *Chrysobötrya intermedia* and *C. Lindleiana*, Spach). Similar to the preceding species, but smaller and slenderer in every part: young shoots glabrous or pubescent: lvs. orbicular-reniform to obovate, 3-lobed and slightly crenate-dentate, cuneate to subcordate at the base, 1-2 in. broad, pubescent or glabrous; petioles about as long as the blades; racemes 5-15-fld.; bracts oblong to obovate; fls. yellow, fragrant or slightly fragrant; calyx-tube slender, $\frac{1}{4}$ - $\frac{1}{2}$ in. long or slightly longer; sepals $\frac{1}{2}$ to nearly $\frac{1}{2}$ in. long, spreading, upright in the faded fl.; petals shorter than half as long as sepals; fr. globose, red or black, $\frac{1}{4}$ - $\frac{1}{2}$ in. thick. Wash. to Calif., west to Assiniboia, Mont., Colo., and N. Mex. B.R. 1274. Var. *chrysococcum*, Rydb. Fr. yellow. Var. *leiobötryx*, Zabel (*R. leiobötryx*, Koehne). Quite glabrous, glandular while young: sepals recurved, calyx-tube longer.—The shrub cult. as *R. aureum* is usually the preceding species which has more showy and fragrant fls.

3. *Gordonianum*, Lem. (*R. Beatonii*, Hort. *R. Loüdonii*, Hort. *R. odoratum* $\times$ *R. sanguineum*). Intermediate between the parents. Habit of *R. odoratum*: lvs. usually 3-lobed, glabrous, truncate at the base; racemes about 20-fld.; fls. yellow, tinged red outside, somewhat glandular, sterile. Originated in England about 1840.—Hardier than the following species, though not quite so handsome in flower.

4. *sanguineum*, Pursh (*Calobötrya sanguinea*, Spach). Shrub, to 10 ft., more or less glandular and aromatic: branchlets pubes-

cent and glandular while young: lvs. cordate or nearly truncate, reniform-orbicular, 3-5-lobed with obtuse irregularly dentate lobes, dark green and puberulous above, whitish-tomentose beneath, 2-4 in. broad; petioles pubescent and glandular: racemes many-fld., pubescent and glandular; bracts oblanceolate; fls. red, pubescent; ovary glandular; calyx-tube about $\frac{1}{2}$ in.

long, sepals slightly longer; petals white or reddish: fr. blue-black, bloomy, slightly glandular. Brit. Col. to N. W. Calif. B.M. 3335. B.R. 1349. Gn. 51:208, fig. 1. H.U. 6:260.—Of this handsome shrub several varieties are in cult. Var. *atrorubens*, Loud. (var. *atrosanguineum*, Kirchn.). Var. *splendens*, Barbier. Fls. dark blood-red, larger than those of the preceding variety. R.H. 1913:428. G. 35:363. Var. *carneum*, Dipp. (*R. carneum grandiflorum*, Carr.). Fls. pink. Var. *albescens*, Rehd. (*R. sanguineum* var. *albidum*, Hort., not Kirchn.). Fls. whitish. Gn. 51:208, fig. 2 (as *R. album*). G.M. 53:125. This variety is usually confused with *R. glutinosum* var. *albidum*, Jancz. (*R. albidum*, Paxt.), which differs chiefly in the glabrescent under side

of the more deeply lobed and more sharply serrate lvs., in the more pendulous racemes with the pedicels $\frac{1}{4}$ - $\frac{1}{2}$ in. long, longer than the recurved narrower bracts. Var. *flöre-pléno*, Hort. With double red fls. P.M. 12:121. F.S. 1, p. 247. G.C. II. 14:144. Var. *Brocklebankii*, Bean. With yellow foliage. Gn. 78, p. 311.

5. *viscosissimum*, Pursh. Shrub, to 3 ft.: young growth and infl. glandular-pubescent and viscid: lvs. grayish green, reniform-orbicular, 5-lobed, with rounded crenately dentate lobes, glandular-pubescent on both sides, 2-3 in. broad; petioles shorter than blade, glandular-pubescent: fls. fragrant, greenish white or pinkish, in 3-8-fld. racemes; ovary glandular; tube cylindric-campanulate, about $\frac{1}{2}$ in. long; sepals about as long as tube; fr. black, not bloomy, glandular-hairy. Brit. Col. to Mont., Colo. and Calif.

6. *cereum*, Douglas. Much-branched, upright shrub, to 4 ft.: young growth puberulous and glandular: lvs. reniform-orbicular, 3-5-lobed with obtuse crenulate lobes, puberulous-glandular beneath, often glabrous or nearly so above, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. broad; racemes few-fld., pendulous; bracts cuneate-obovate, toothed at the rounded or truncate apex; fls. white or greenish; calyx-tube pubescent, $\frac{1}{4}$ - $\frac{1}{2}$ in. long, sepals ovate, about as long; petals minute, orbicular; ovary glandular or smooth; style usually hairy above: fr. bright red, about $\frac{1}{2}$ in. across. Brit. Col. to Calif., east to Mont., Idaho, Utah, and Ariz. B.M. 3008. B.R. 1263.—Early leafing and conspicuous with its pale grayish green foliage studded with numerous white or pinkish fls.; also the bright red frs. are ornamental. Var. *farinösum* (var. *farinösum carneum*, Jancz.). Branchlets violet: lvs. whitish-pulverulent: fls. bright pink.

7. *inebrians*, Lindl. (*R. Spaethianum*, Koehne). Fig. 3403. Similar to the preceding species in habit and

3403. *Ribes inebrians*. ($\times \frac{3}{4}$)

foliage: racemes few-fl'd.; bracts rhombic, usually acute, entire or occasionally with a lateral lobe; fls. usually pink; style glabrous; ovary with stalked glands: fr. bright red, usually glandular. S. D. and Mont. to Nev., Cent. Calif., Ariz. and New Mex. B.R. 1471. B.B. (ed. 2) 2:238.—A hybrid between this and the preceding species is *R. Berlandieri*, Jancz.

8. *americānum*, Mill. (*R. floridum*, L'Her. *R. pennsylvanicum*, Lam. *R. missouriense*, Hort.). AMERICAN BLACK CURRANT. Upright shrub, to 5 ft., with rather slender arching branches: young shoots slightly pubescent and glandular: lvs. suborbicular, cordate or nearly truncate, 3-5-lobed with acute, or sometimes obtuse, dentate lobes, more or less pubescent at least on the veins, resinous-dotted beneath, 1-3 in. broad: racemes pendulous, many-fl'd.; bracts linear to linear-lanceolate; fls. greenish white or yellowish; bracts longer than pedicels; ovary glabrous; tube cylindric-campanulate, $\frac{1}{2}$ in. long, sepals obtuse, slightly longer, pubescent; petals and stamens about two-thirds as long as sepals: fr. black, smooth. Nova Scotia to Va., west to Man. and Colo. G.O.H. 1. B.B. (ed. 2) 2:238.—Foliage with the peculiar heavy odor of the following species, turning crimson and yellow in autumn.

9. *nigrum*, Linn. EUROPEAN BLACK CURRANT. Upright shrub, to 6 ft., with rather stout branches, of strong disagreeable odor: lvs. suborbicular, cordate, 3-5-lobed, with broad, acutish irregularly serrate lobes, sparingly pubescent, resinous-dotted beneath, to 4 in. broad: racemes 5-10-fl'd.; bracts small, much shorter than the pedicels; ovary and calyx pubescent and glandular; calyx-tube broadly campanulate; sepals oblong, recurved; petals reddish or whitish, about half as long as sepals: fr. black, subglobose, $\frac{1}{2}$ - $\frac{2}{3}$ in. thick. Eu., N. and Cent. Asia, Himalayas. S.E.B. 4:523. R.F.G. 23:137.—Sometimes cult. for its fr. and escaped in the eastern and middle states. Var. *heterophyllum*, Pépin (var. *aconitifolium*, Kirchn., var. *crispum*, Hort., var. *laciniatum*, Lav.). With divided lvs., sometimes nearly to the base, the lobes irregularly and deeply incised. Var. *apiifolium*, Kirchn. (var. *dissectum*, Nichols.). Lvs. 3-parted, usually to the base, the lobes pinnatifid with narrow segms. Var. *xanthocarpum*, Spaeth (var. *fructu-viride*, Hort.). Fr. yellow. Var. *chlorocarpum*, Spaeth (var. *fructu-viridi*, Hort.). Fr. greenish. Gt. 16:562, fig. 16. There are also forms with variegated lvs. as var. *variegatum*, Nichols., var. *marmoratum*, Mouillef., and var. *reticulatum*, Nichols.

10. *bracteosum*, Douglas. CALIFORNIAN BLACK CURRANT. Shrub, to 8 ft., with upright or ascending sts.: young growth sparingly pubescent and resinous-dotted: lvs. thin, cordate, deeply 5-7-lobed, with ovate to ovate-lanceolate, acute, sharply serrate lobes, 2-8 in. broad: racemes narrow, slender, upright, often 8 in. long; bracts spatulate, half as long as the pedicels, the lower foliaceous; fls. greenish or purplish; calyx-tube cup-shaped; sepals spreading, ovate-oblong, $\frac{1}{2}$ in. long; petals minute, obtuse: fr. globose, black with whitish bloom, resinous-dotted, edible. Alaska to N. Calif. B.M. 7419.—Hardy at the Arnold Arboretum; remarkable for its large maple-like lvs. and the long bracted racemes. A hybrid of this species with *R. nigrum* is *R. fuscescens*, Jancz. (*R. bracteosum* var. *fuscescens*, Jancz.). It differs chiefly in its reddish brown fls., in the small linear bracts of the spreading or arching infl., and in the larger fr. Gt. 55, p. 162. Originated in Scotland.

11. *glandulosum*, Grauer (*R. prostratum*, L'Her. *R. rigens*, Michx.). FETID CURRANT. SKUNK CURRANT. Decumbent shrub with prostrate or spreading and reclining sts. and ascending branches: young growth sparingly pubescent and sparingly glandular: lvs. thin, fetid, orbicular, cordate, deeply 5-7-lobed, with ovate-acute or acutish, doubly serrate lobes, glabrous above, pubescent on the veins beneath, $1\frac{1}{2}$ -3 in. broad:

racemes ascending, 8-12-fl'd.; pedicels filiform, glandular, much longer than the narrow bracts; fls. whitish or pinkish; ovary glandular-hispid; calyx-tube cup-shaped; sepals short, spreading, glabrous outside: fr. red, glandular-bristly. Newfoundland to Brit. Col.; south to Mich. and Minn. and in the mountains to N. C. B.B. (ed. 2) 2:238.

12. *triste*, Pall. SWAMP RED CURRANT. Low shrub with creeping or ascending, often rooting sts.: young growth sparingly pubescent and sparingly glandular: lvs. thin, suborbicular, 3-5-lobed, with acute or obtuse, coarsely serrate lobes, dark green and glabrous above, pubescent or whitish-tomentose beneath, 2-4 in. broad: racemes drooping, $1\frac{1}{2}$ - $3\frac{1}{2}$ in. long; pedicels longer than the ovate bracts; fls. purplish; calyx-tube saucer-shaped; sepals spreading, obtuse; petals reddish: fr. red, smooth. N. Asia and boreal N. Amer., south to Maine and Vt. B.B. (ed. 2) 2:237. Var. *albinervium*, Fern. (*R. albinervium*, Michx.). Lvs. glabrous or nearly so beneath. N. Amer., south to N. H., Mich. and Wis.

13. *petraeum*, Wulf. (*R. bullatum*, Otto and Dietr.). Upright shrub, to 8 ft.: branches usually glabrous: lvs.

3404. *Ribes vulgare*.—The common currant. (Natural size.) No. 15.

roundish, subcordate or truncate, usually 3-lobed, with acutish lobes, rugose, pubescent beneath, 3-4 in. broad: racemes dense, to 4 in. long; fls. red or pink; pedicels short; bracts very small; calyx-tube broadly campanulate with short spreading rounded ciliate sepals; petals nearly half as long as sepals, with a callosity below the base: fr. dark red, acid. Mts. of Cent. and S. Eu., Caucasus, N. Asia. R.F.G. 23:138. Var. *carpathicum*, Jancz. (*R. carpathicum*, Kit.). Lvs. usually 3-lobed, rugose, glabrescent: racemes looser and smaller. Carpathian Mts. Var. *Biebersteinii*, Jancz. (*R. Biebersteinii*, Berl. *R. caucasicum*, Bieb. *R. macrobotrys*, Hort.). Lvs. usually 5-lobed, with short obtuse lobes, cordate, not rugose, glabrescent or pubescent: racemes long; fls. reddish: fr. red or blackish purple. Caucasus. Var. *atropurpureum*, Jancz. (*R. atropurpureum*, C. A. Mey.). Lvs. subcordate or truncate, usually 3-lobed, with acutish lobes, not rugose, glabrescent or pubescent beneath, to 6 in. broad: racemes short; fls. purple; the disk inside without callosities: fr. red or blackish purple. Siberia.

14. *multiflorum*, Kit. Upright shrub with stout branches: winter buds large: lvs. roundish, subcordate or truncate, 3-5-lobed with acutish or obtusish, crenately dentate lobes, pubescent beneath, to 4 in. broad: racemes pendulous, dense, to 6 in. long, sometimes about 50-fl'd.; pedicels short; fls. greenish yellow; calyx-tube saucer-shaped; sepals reflexed; petals minute;

stamens and style equaling the sepals: fr. dark red, smooth. S. Eu. B.M. 2368. L.B.C. 14:1331. R.F.G. 23:138a. L.I. 31.

15. *vulgäre*, Lam. (*R. hortense*, Hedl. *R. sativum*, Syme. *R. rubrum* of many authors, not Linn.). RED or GARDEN CURRANTS. Fig. 3404. Upright shrub, to 5 ft.: young growth pubescent and slightly glandular: lvs. thin, cordate or subcordate, 3-5-lobed, with short-ovate, acutish, serrate lobes, pubescent at least on the veins beneath, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. broad: racemes drooping, many-fld., glabrous or nearly so; pedicels filiform, much longer than the ovate bracts; calyx-tube saucer-shaped, green or slightly purple inside between the stamens and the style with an elevated slightly 5-angled ring; anthers with a broad connective separating the cells: fr. red, whitish, or striped, juicy, the dried remnants of the fl. 5-angled at the base. W. Eu. S.E.B. 4:520. B.B. (ed. 2) 2:237. Var. *macrocarpum*, Jancz. (*R. acerifolium*, Hort.). Of irregular habit on account of the lateral branchlets being partly without buds: lvs. large, deeply cordate, 3-lobed, with a very large middle lobe: racemes without lvs. at the base: fr. large, always red. To this variety belong most of the large-fruited "cherry currants," tenderer than the typical form. *R. vulgäre* is the parent of most of the cult. currants. Some of the hardier and smaller-fruited varieties are probably crosses with the hardier *R. rubrum*; they have been named *R. Houghtonianum*, Jancz. Other hybrids of this species are *R. Goudotii*, Jancz. (*R. vulgäre* $\times$ *R. petraeum*). *R. Koehneanum*, Jancz. (*R. vulgäre* $\times$ *R. multiflorum*) and *R. futurum*, Jancz. (*R. vulgäre* $\times$ *R. Warscewiczii*).

16. *rubrum*, Linn. (*R. Schlechtendalii*, Lange. *R. sylvestre*, Syme. *R. scandinavicum*, Hedl.). NORTHERN RED CURRANT. Shrub, to 6 ft.: young growth usually glabrous: lvs. truncate, rarely subcordate, 3-5-lobed, usually nearly glabrous, to 5 in. across: racemes usually spreading; pedicels short; bracts very small; fls. greenish or brownish; calyx-tube saucer-shaped, without prominent ring inside; anthers with contiguous cells: fr. usually red, juicy, the dried remnants of the fl. circular at the base. Cent. and N. Eu. N. Asia. S.E.B. 4:522. Var. *pubescens*, Swartz. Young shoots slightly pubescent: lvs. pubescent beneath: racemes shorter; fls. brown or pinkish: fr. small. N. Eu. Var. *glabellum*, Trautv. & Mey. Young branchlets and lvs. glabrous: fls. larger, pink or brownish red: fr. larger. N. Asia.—*R. rubrum* is rare in cult. outside of the gardens of N. Eu. where forms with red, pink or whitish frs. are grown. Besides *R. Houghtonianum*, mentioned under the preceding species, two other crosses of *R. rubrum* are known: *R. pallidum*, Otto. & Dietr. (*R. rubrum* $\times$ *R. petraeum*), and *R. holosericeum*, Otto & Dietr. (*R. rubrum* $\times$ *R. petraeum* var. *caucasicum*).

17. *fasciculatum*, Sieb. & Zucc. (*R. japonicum*, Carr., not Maxim. *R. alpinum japonicum*, Nichols.). Shrub, to 4 ft., with upright or ascending branches: lvs. subchartaceous, truncate to cordate, 3-5-lobed, with obtusish lobes, glabrous or slightly pubescent, to 5 in. across: fls. dioecious, small, greenish; male fls. in 4-9 fld. clusters, pistillate fls. 2-4; calyx-tube cup-shaped; anthers subsessile: fr. subglobose, scarlet, glabrous, $\frac{1}{2}$ in. across, insipid. April, May; fr. in Sept., Oct. Japan. Var. *chinense*, Maxim. (*R. Billiardii*, Carr.). Lvs. larger, persisting until the beginning of the winter, lobes more acutish, pubescent beneath like the petioles and young branchlets. N. China. S.T.S. 1:38. M.D.G. 1899:571.—Handsome shrub chiefly valued for its late persisting foliage and the bright scarlet berries remaining on the branches during the whole winter.

18. *alpinum*, Linn. (*R. opulifolium*, Hort.). ALPINE CURRANT. Dense shrub, attaining 8 ft. and as much or more through, with upright sts. and spreading branches, nearly glabrous: lvs. truncate or subcordate, 3-lobed, rarely 5-lobed, with obtuse or acutish dentate lobes,

1-2 in. across: fls. dioecious, small, greenish, in upright racemes, the male 1-2 $\frac{1}{2}$, the female $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long; the calyx-tube nearly flat; sepals ovate, petals minute; filaments very short: fr. subglobose, scarlet, glabrous, insipid. Eu. L.B.C. 15:1486. S.E.B. 4:519. R.F.G. 23:135.—Several named varieties of little importance are known; the best known are: Var. *pumilum*, Lindl. (var. *humile*, A. Braun). Dwarf form with smaller lvs. Var. *laciniatum*, Kirchn. Lvs. more deeply lobed and incisely toothed. Var. *adereum*, Bean (var. *pumilum adereum*, Pynaert, var. *foliis-aureis*, Hort.). Dwarf form with yellowish foliage. R.B. 4:233. The pistillate fruiting form is sometimes distinguished as var. *bacciferum*, Loud., and the staminate sterile form as var. *sterile*, Loud.—The Alpine currant is a desirable shrub of dense habit, unfolding very early its bright green foliage, adorned in summer and autumn with bright scarlet berries; it is one of the best shrubs to plant as undergrowth and in shady places.

19. *diacantha*, Pall. (*R. saxatile*, Pall.). Upright shrub, to 6 ft.: branches glabrous, slender, upright, with paired small slender prickles at the nodes or unarmed: lvs. oval or cuneate-obovate, 3-lobed with sparingly dentate, obtusish lobes, glabrous, lustrous, with obsolete veins, $\frac{3}{4}$ -1 $\frac{3}{4}$ in. long; petioles about $\frac{1}{2}$ in. long: fls. dioecious, small, greenish, in upright racemes, the staminate about 1 $\frac{1}{2}$ in. long, the pistillate $\frac{1}{2}$ - $\frac{3}{4}$ in. long; calyx-tube flat; sepals oval, petals minute: fr. subglobose or somewhat ovoid, scarlet. N. Asia.—Like the preceding species desirable for its bright green more lustrous foliage and for its scarlet fr., but habit upright, not spreading.

20. *lacustre*, Poir. SWAMP BLACK CURRANT, or SWAMP GOOSEBERRY. Shrub with slender weak sts., usually densely bristly; prickles slender, often clustered: lvs. nearly orbicular, cordate, deeply 3-7-lobed, with acutish, incisely dentate lobes, glabrous or nearly so, 1 $\frac{1}{2}$ -2 in. across: racemes spreading or drooping, 10-15-fld.; fls. greenish or purplish; calyx-tube saucer-shaped; sepals spreading, broad and short; stamens very short: fr. subglobose, purple-black, with gland-tipped bristles. Newfoundland to Alaska, south to Mass., Mich., Minn., Colo., and Calif. L.B.C. 9:884. B.M. 6492.

Section 2. GROSSULARIA. Gooseberries.

21. *niveum*, Lindl. (*Grossularia nivea*, Spach). Shrub, to 8 ft., upright or ascending: branches reddish brown, with stout brown prickles $\frac{1}{2}$ - $\frac{3}{4}$ in. long, without bristles: lvs. suborbicular, thin, 3-5-lobed, with

3405. *Ribes hirtellum*.—Parent of some of the American garden gooseberries. ($\times\frac{1}{2}$)

few-toothed obtusish lobes, sparingly pubescent or glabrous, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. 1-4, white, on slender peduncles; bracts ovate, small, much shorter than the filiform pedicels; ovary glabrous; tube campanulate, sepals narrowly lanceolate, $\frac{1}{4}$ - $\frac{1}{2}$ in. long; stamens slightly longer than the sepals, with pubescent fila-

ments: fr. globose, bluish black, glabrous, subacid. Idaho and Wash. to Nev. B.R. 1962.—Attractive in bloom with its numerous white fls.

22. *curvatum*, Small (*Grossularia curvata*, Cov. & Brit.). Diffusely branched shrub, to 3 ft., with slender reddish brown or purplish branches, spines slender, about $\frac{1}{8}$ in. long: lvs. suborbicular, cuneate to subcordate, with obtusish, toothed lobes, sparingly pubescent, $\frac{1}{2}$ –1 in. across: fls. 1–5, white, on slender peduncles; bracts ovate, often 3-lobed, ciliate, much shorter than the slender pedicels; ovary glandular or pubescent; tube broadly campanulate; sepals linear-spatulate, about $\frac{1}{4}$ in. long, revolute; petals small, lanceolate, toothed; stamens conspicuous, as long as the sepals, with villous filaments: fr. globose, greenish, $\frac{1}{4}$ – $\frac{1}{2}$ in. across, glabrous. Ga. to La. and Texas.—Graceful little shrub, similar to the preceding species, but slenderer and more spreading; perfectly hardy at the Arnold Arboretum.

23. *missouriense*, Nutt. (*R. gracile* Pursh, not Michx. *R. rotundifolium*, Jancz., not Michx. *Grossularia missouriensis*, Cov. & Brit.). Shrub, to 6 ft., with smooth or sometimes bristly, grayish or whitish branches: spines about $\frac{3}{4}$ in. long or shorter: lvs. suborbicular, broadly cuneate to subcordate at the base, 3–5-lobed, with coarsely dentate obtusish lobes, pubescent beneath, $\frac{3}{4}$ –2 $\frac{1}{2}$ in. broad: fls. greenish white, 2–3, on slender peduncles $\frac{1}{3}$ – $\frac{3}{4}$ in. long; pedicels slender, much longer than the bracts; ovary glabrous; calyx-tube cylindric-campanulate; sepals linear, about $\frac{1}{2}$ in. long; filaments glabrous, nearly twice as long as sepals; style pubescent below: fr. globose, $\frac{1}{2}$ – $\frac{1}{2}$ in. across, purplish, glabrous, subacid. Ill. to Minn., S. D., Kans., Mo. and Tenn. B.B. (ed. 2) 2:240.

24. *oxyacanthoides*, Linn. (*Grossularia oxyacanthoides*, Mill.). Low shrub with slender, often reclining branches, usually more or less bristly and with spines about $\frac{1}{2}$ in. long, sometimes nearly wanting: lvs. suborbicular, cordate to broadly cuneate at the base, deeply 5-lobed with dentate lobes, slightly pubescent or nearly glabrous, 1–2 in. broad: peduncles very short, scarcely exceeding the bud-scales, 1–2-flid.; pedicels short: fls. greenish white; sepals narrow-oblong, little longer than the tube; stamens somewhat shorter than the sepals: fr. globose, smooth, red, slightly bloomy, edible. Newfoundland to Brit. Col., south to Mont., N. D., and Mich. B.B. (ed. 2) 2:240.—The plant cult. as *R. oxyacanthoides* is usually *R. hirtellum* or *R. inerme*.

25. *setosum*, Lindl. (*R. saximontanum*, E. Nelson. *Grossularia setosa*, Cov. & Brit.). Shrub, to 3 ft., with reddish brown usually bristly branches: spines subulate, $\frac{3}{4}$ in. or less long: lvs. suborbicular, cordate to truncate, rarely broadly cuneate, 3–5-lobed, with dentate lobes, finely pubescent and usually somewhat glandular, $\frac{1}{2}$ –1 $\frac{1}{2}$ in. wide: fls. 1–4, white; calyx-tube cylindric-campanulate, glabrous, about twice as long as the sepals; petals half or two-thirds as long as the sepals, as long as the stamens; style pubescent below: fr. red to black, glabrous or somewhat bristly. Idaho to Assiniboia, S. D., and Wyo. B.R. 1237. B.B. (ed. 2) 2:240.

26. *hirtellum*, Michx. (*R. saxosum*, Hook. *R. gracile*, Jancz., not Michx. *R. oxyacanthoides* of many authors, not Linn. *Grossularia hirtella*, Spach). Fig. 3405. Shrub, to 4 ft., with slender branches, usually unarmed, sometimes with subulate small spines, only at the base of vigorous shoots bristly: lvs. suborbicular, usually cuneate, incisedly 3–5-lobed, with dentate, acute lobes, glabrous or sparingly pubescent, 1–2 in. broad; petioles often with long hairs: fls. 1–3, greenish; bracts much shorter than pedicels; ovary glabrous, rarely with stalked glands; calyx-tube narrow-campanulate; sepals oblong, often purplish, glabrous; stamens as long as sepals, petals half as long; style pubescent: fr. globose, smooth or rarely with stalked glands, purple or black,

edible. Newfoundland to Pa. and W. Va., west to Man. and S. D. B.M. 6892 (as *R. oxyacanthoides*). B.B. (ed. 2) 2:241.—This is the most important of the edible American gooseberries and there are in cult. several hybrids with *R. Grossularia*, designated as *R. rusticum*, Jancz., to which such varieties as Downing,

3406. Ribes Cynosbati. ($\times \frac{1}{2}$)

Houghton, and Smith are thought to belong, while Pale Red appears to be of pure *R. hirtellum* parentage.

27. *rotundifolium*, Michx. (*R. triflorum*, Willd. *Grossularia rotundifolia*, Cov. & Brit.). Shrub, to 3 ft., with slender brown branches, or the younger ones gray; spines small, sparse, rarely over $\frac{1}{2}$ in. long: lvs. suborbicular, broadly cuneate to subcordate at the base, usually 3-lobed, with coarsely dentate obtusish lobes, minutely pubescent or nearly glabrous, 1–2 in. broad: fls. 1–3, purplish; peduncles slender; pedicels much longer than the small bracts; fls. greenish purple; calyx-tube campanulate; sepals linear, about twice as long as tube; petals obovate; stamens somewhat longer than the sepals; fr. globose, smooth, purplish. L.B.C. 11:1094. G.O.H. 3. B.B. (ed. 2) 2:241.—This species is rare in gardens; usually the following species is cult. under this name.

28. *divaricatum*, Douglas (*R. divaricatum* var. *Douglasii*, Jancz. *R. irriguum*, Koehne, not Douglas. *Grossularia divaricata*, Cov. & Brit.). Shrub, to 10 ft.; branches gray to brown, with stout spines $\frac{1}{2}$ – $\frac{3}{4}$ in. long, sometimes unarmed and sometimes bristly: lvs. suborbicular, cordate to subtruncate, usually 5-lobed, with coarsely crenate-dentate obtusish lobes, pubescent beneath along the veins or glabrous, 1–2 $\frac{1}{2}$ in. broad: fls. 2–4, greenish purple; peduncles slender; bracts ovate, small; ovary glabrous; calyx-tube campanulate; sepals oblong, longer than tube; stamens slightly longer than the sepals; fr. globose, smooth, black or dark purple. Brit. Col. to Calif. B.R. 1359. Var. *pubiflorum*, Koehne (*R. divaricatum* var. *villosum*, Zabel). Lvs. pubescent: fls. smaller; vigorous sts. bristly. Var. *montanum*, Jancz. Low shrub with almost prostrate branches, smaller in every part. Calif.

29. *inerme*, Rydb. (*R. hirtellum Purpusii*, Koehne. *R. oxyacanthoides* var. *nevadense* and var. *irriguum*, Jancz. *Grossularia inermis*, Cov. & Brit.). Shrub, to 6 ft.: branches with few small spines less than $\frac{1}{2}$ in. long, sometimes unarmed, rarely with a few bristles: lvs. suborbicular, cordate to truncate at the base, 3–5-lobed with crenate-dentate obtusish lobes, glabrous or sometimes pubescent, $\frac{1}{2}$ –2 $\frac{1}{2}$ in. broad: fls. 1–4, green or purplish; bracts small; ovary glabrous; calyx-tube narrowly campanulate; sepals oblong, slightly shorter than tube; stamens shorter than sepals: fr. purplish red, smooth, edible. Mont. to Brit. Col. to Calif. and New Mex.

30. *Grossularia*, Linn. (*Grossularia reclinata*, Mill.). Shrub, to 3 ft.: branches ascending or reclining, with stout spines, about $\frac{1}{2}$ in. long, mostly in 3's, st. sometimes bristly: lvs. suborbicular, cordate to broadly

cuneate, 3-5-lobed with crenulate-dentate, obtusish lobes, pubescent or glabrous, $\frac{3}{4}$ -2 $\frac{1}{2}$ in. broad: fls. 1-2, greenish; bracts small; ovary pubescent and often glandular; calyx-tube short-campanulate, about as long as the usually pubescent reflexed sepals; stamens shorter than sepals; style pubescent: fr. globose to ovoid, usually pubescent and glandular-bristly. Eu., N. Afr., Caucasus. S.E.B. 4:518. R.F.G. 23:134. Var. *Ūva-crispa*, Smith (var. *pubescens*, W. D. Koch. *R. Ūva-crispa*, Linn.). Low shrub: lvs. smaller, pubescent; ovary pubescent, not glandular: fr. very small, yellowish, pubescent. Var. *reclinatum*, Berl. (var. *glabrum*, W. D. Koch. *R. reclinatum*, Linn.). Lvs., calyx and fr. glabrous.—This species is the parent of the European gooseberries.

31. *Cynósbati*, Linn. (*R. grácile*, Michx. *Grossulària Cynósbati*, Mill.). Fig. 3406. Shrub, to 5 ft., but usually lower, with spreading branches: spines slender, 1-3, $\frac{1}{4}$ - $\frac{2}{5}$ in. long: bristles few and weak or none: lvs. orbicular, truncate or cordate, deeply 3-5-lobed, with crenately or incisely dentate lobes, usually pubescent beneath, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. broad: fls. 1-3, on slender stalks, green, ovary setose; calyx-tube broadly campanulate; sepals shorter than tube; petals about half as long; stamens little longer than petals: fr. globose or ovoid, vinous-red, prickly, edible. New Bruns. to N. C., west to Man., Mo. and Ala. B.B. (ed. 2) 2:239. Var. *inérme*, Rehd. Fr. without prickles, smooth. Var. *glabrátum*, Fern. Lvs. glabrous or only sparingly pilose on the veins.

32. *alpêtre*, Decne. Upright shrub, to 10 ft.: branches with stout spines to $\frac{3}{4}$ in. long and usually in 3's, often bristly: lvs. cordate to truncate, 3-5-lobed, with incisely dentate, obtusish lobes, 1-2 in. broad: fls. 1-2, short-peduncled, greenish or sometimes reddish;

far north as Mass.; in W. China, E. H. Wilson found hedges 6-8 ft. high so thick and spiny that a yak, an animal as strong as an ox, could not break through them.

33. *pinetòrum*, Greene (*Grossulària pinetòrum*, Cov. & Brit.). Shrub, to 6 ft., with spreading and reclining branches, without bristles: spines 1-3, $\frac{1}{2}$ in. long or less: lvs. suborbicular, thin, cordate, usually 5-cleft, with obtuse irregularly incised-dentate lobes, dull green and glabrous above, puberulous beneath at least on the veins, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. broad: fls. solitary, orange-red; bracts small, ciliate; ovary bristly; calyx-tube campanulate, pilose; sepals spatulate, reflexed, nearly twice as long as tube; petals orange, only one-third shorter than the sepals; stamens as long as petals: fr. globose, prickly, purple. Ariz., New Mex.—Hardy at the Arnold Arboretum; very striking on account of the unusual orange-red color of the fls.

34. *Roëzlii*, Regel (*R. amictum*, Greene. *R. aridum*, Greene. *R. Wilsonianum*, Greene. *Grossulària Roëzlii*, Cov. & Brit.). Shrub, to 5 ft., with pubescent branchlets; bristles wanting; spines slender, about $\frac{1}{2}$ in. long: lvs. thin, reniform-orbicular, truncate or subcordate, 3-5-lobed with incisely crenate-dentate lobes, finely pubescent on both sides or glabrous above, $\frac{1}{2}$ -1 in. broad: fls. 1-3, purple; bracts longer or sometimes shorter than pedicels; ovary bristly and usually white-hairy; calyx-tube cylindric-campanulate, pubescent; sepals lanceolate, longer than tube; petals white or pinkish, nearly half as long as sepals; stamens slightly longer than sepals; anthers sagittate: fr. globose, prickly, purple. Cent. and S. Calif. Gt. 28:982, figs. 1-3. R.H. 1899, p. 177. Var. *cruentum*, Rehd. (*R. cruentum*, Greene. *R. amictum* var. *cruentum*, Jancz.). Lvs. and fls. glabrous. Ore. to Cent. Calif. B.M. 8105.

3407. *Ribes Lobbii*. (Natural size.)

calyx-tube campanulate, glandular; sepals oblong, reflexed, about as long as tube; petals white, elliptic, at least half as long as sepals; ovary with gland-tipped bristly hairs: fr. globose or ovoid, to $\frac{3}{4}$ in. long, with gland-tipped bristles. Himalayas, W. China. Var. *gigantèum*, Jancz. Shrub, to 15 ft. with stout spines over 1 in. long: fls. glabrous, with smooth ovary: fr. larger, smooth, green. W. China.—*R. alpestre* may prove to be a desirable hedge-plant, hardy at least as

R.H. 1908, p. 32.—Very handsome in fl., particularly on account of the contrast between the purple calyx and the white petals.

35. *Lóbbii*, Gray (*Grossulària Lóbbii*, Cov. & Brit.). Fig. 3407. Shrub, to 6 ft.; branchlets pubescent, rarely with a few bristles; spines 3, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: lvs. thin, suborbicular, cordate or subcordate, 3-5-lobed, with crenate-dentate obtuse lobes, sparingly pubescent when young and glandular, or glabrous above, $\frac{3}{4}$ -1 $\frac{1}{2}$ in.

broad; fls. 1-2, purple-red, rather large; peduncles glandular-pubescent; bracts ovate, as long as pedicels or shorter; ovary stipitate, glandular; calyx-tube narrow-campanulate, finely pubescent; sepals reflexed, 2-3 times as long as the tube; petals whitish, half as long as sepals; stamens twice as long as petals; anthers oblong, glandular on back; fr. ovoid, purple, densely glandular. Brit. Col. to N. Calif. B.M. 4931 (as *R. subvestitum*). R.H. 1908, p. 30. G.C. II. 19:11.

36. *speciosum*, Pursh (*R. fuchsiaeoides*, Moc. & Sessé. *Grossularia speciosa*, Cov. & Brit.). Fig. 3408. Evergreen shrub, to 12 ft., with stout sts.; branches usually bristly; spines 3, stout, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; lvs. coriaceous, orbicular to obovate, rounded to broadly cuneate, 3-5-lobed or crenate-dentate, glabrous or sparingly glandular-hairy, lustrous above, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long; fls. 2-4, bright red, on slender pendulous peduncles, 4-merous; tube broadly campanulate; sepals upright, parallel, about $\frac{1}{3}$ in. long, about as long as the scarlet convolute petals; stamens 2-4 times as long as petals; fr. ovoid, glandular-bristly, red. Calif. B.R. 1557. B.M. 3530. Gn. 9, p. 586; 31, p. 333; 34, p. 230. G.C. III. 34:71. R.H. 1900:98; 1908, p. 29. J.H. III. 54:207.—One of the most showy gooseberries, but not hardy North.

R. aciculare, Smith. Allied to *R. Grossularia*. Spiny shrub; branches slender, bristly; lvs. 3-5-lobed, usually glabrous, about 1 in. broad; fls. pinkish; sepals reflexed; style glabrous; fr. smooth, rarely hispid, red or greenish yellow. Cent. Siberia, Altai Mts. The earliest gooseberry to burst into leaf.—*R. affine*, Douglas=*R. laxiflorum*.—*R. albidum*, Paxt.=*R. glutinosum albidum*.—*R. ambiguum*, Maxim. Low unarmed shrub; lvs. roundish, 3-5-lobed, with short, obtuse lobes, viscid-glandular beneath, to 2 in. broad; fls. 1-2, greenish; tube saucer-shaped; stamens shorter than sepals; fr. green, glandular-bristly. Japan.—*R. ambiguum*, Wats.=*R. Watsonianum*.—*R. burejense*, F. Schmidt. Allied to *R. alpestre*. Spiny and bristly shrub, to 3 ft.; lvs. deeply 3-5-lobed, pubescent and glandular, to 2 in. broad; fls. 1-2, reddish brown or pale; fr. greenish, prickly. N. E. Asia.—*R. californicum*, Hook. & Arn.=*R. occidentale*.—*R. Carrièrei*, Schneid. (*R. intermedium*, Carr., not Tausch. *R. glutinosum albidum* $\times$ *R. nigrum*). Intermediate between the parents: lvs. without the odor of *R. nigrum*; fls. pink, glandular, in horizontal racemes to 3 in. long; fr. black, not bloomy. Originated with Billiard at Fontenay-aux-Roses, France.—*R. cognatum*, Greene (*R. palousense*, Elmer). Allied to *R. oxycanthoides*. Spiny shrub to 10 ft., sometimes without bristles; fls. 2-5, white or whitish; calyx-tube cylindric, longer than sepals; stamens about half as long as sepals; fr. smooth. Wash., Ore.—*R. coloradense*, Cov. (*R. laxiflorum* var. *coloradense*, Jancz.). Allied to *R. glandulosum*. Unarmed procumbent shrub; lvs. usually 5-lobed; sepals longer, glandular-pubescent outside; fr. black, not bloomy. Colo.—*R. Cuberwellii*, Macfarlane (*R. Schneideri*, Maurer. *R. nigrum* $\times$ *R. Grossularia*). Unarmed shrub; fls. similar to those of *R. nigrum*; the glandless lvs. and the infl. resembling those of the gooseberry; fr. dark red, hairy. G.C. III. 12:271; 44:120. J.H.S. 28, pp. 169-73. Originated in England and afterward also in Germany. Var. *wollense* (*R. wollense*, Bean). Lvs. with a few glands beneath; fr. glabrous, shining black.—*R. diküscha*, Fisch. Allied to *R. bracteosum*. Unarmed shrub; lvs. 3-5-lobed, glabrous, glandular beneath, to 5 in. broad; fls. white, tomentose, in upright racemes to 3 in. long; bracts linear, small; fr. bluish black, slightly bloomy. E. Siberia.—*R. erythrospermum*, Cov. & Leiber. Allied to *R. glandulosum*. Unarmed prostrate shrub; lvs. deeply 3-5-lobed, finely pubescent and glandular; racemes erect, 6-10-fld.; bracts about as long as pedicels; fls. yellow or salmon-colored; fr. glandular-hairy, scarlet. Ore. G.F. 10:184.—*R. fontenayense*, Jancz. (*R. sanguineum fontenayense*, Hort. *R. Grossularia* $\times$ *R. sanguineum*). Intermediate between the parents: unarmed shrub; lvs. subcoriaceous, pubescent beneath; racemes horizontal or pendulous, stalked, 3-6-fld.; fls. vinous-red, pubescent; fr. purplish black. Originated in France with Billiard at Fontenay-aux-Roses.—*R. fulvum*, Jancz. (*R. vulgare* $\times$ *R. Warsceviczii*). Intermediate between the parents: fls. brownish red or pinkish; fr. dark red. Raised by Janczewski at Lemberg, Galicia.—*R. Gayanum*, Steud. (*R. villosum*, Gay, not Nutt. *R. trilobum*, Mey.). Evergreen unarmed shrub, to 4 ft., with pubescent branches; lvs. slightly 3-lobed, pubescent, 1-2 in. across; fls. dioecious, yellow, honey-

scented, in erect dense pubescent racemes 1-2 in. long; fr. purple-black, hairy. Chile. B.M. 7611. Not hardy North.—*R. Giraldii*, Jancz. Allied to *R. diacantha*. Spiny shrub, to 2 ft., with spreading bristly branches; lvs. 3-5-lobed, the middle lobe longer, pubescent and glandular, about $\frac{1}{2}$ in. broad; fls. dioecious, brownish, in upright racemes; fr. scarlet, glandular-bristly. N. W. China.—*R. glaciale*, Wall. Allied to *R. alpinum*. Unarmed shrub, to 15 ft.; lvs. cordate to truncate, 3-5-lobed, the middle lobe elongated,

3408. *Ribes speciosum*, the fuchsia-flowered gooseberry. ($\times \frac{1}{2}$)

acute or acuminate, glandular, to $2\frac{1}{2}$ in. long; fls. dioecious, greenish white or purplish, in upright racemes; fr. glabrous, scarlet, finally black. Himalayas, W. China.—*R. glutinosum*, Benth. (*R. sanguineum* var. *glutinosum*, Loud.). Allied to *R. sanguineum*. Unarmed shrub, to 12 ft., with glandular-viscid pubescence; lvs. cordate, 3-5-lobed, glandular beneath, otherwise nearly glabrous, to 4 in. broad; racemes pendulous, to 4 in. long; bracts recurved; fls. pink-carmine; fr. black, glandular-hairy. Calif. Var. *albidum*, Jancz. (*R. sanguineum albidum*, Kirchn. *R. albidum*, Paxt.). Fls. white, tinged pinkish, often confused with *R. sanguineum* var. *albescens*, which see.—*R. Henryi*, Franch. Evergreen unarmed shrub, glandular; lvs. elliptic, crenulate, to 4 in. long; fls. dioecious, small, greenish; pistillate racemes 7-9-fld., with large green bracts; fr. oblong, green, glandular. Cent. China.—*R. himalayense*, Deane. Allied to *R. petraeum*. Unarmed shrub, to 12 ft.; lvs. cordate, 3-5-lobed, with acute or obtusish lobes, glandular above, pubescent or glabrous beneath, to 5 in. broad; fls. greenish, tinged purple, in racemes to 5 in. long, broadly campanulate; fr. red or black. Himalayas, W. China.—*R. hudsonianum*, Rich. Allied to *R. bracteosum*. Unarmed shrub; lvs. 3-5-lobed, resinous-dotted beneath, $1\frac{1}{2}$ -4 in. broad; fls. white, in loose racemes about 2 in. long; bracts setaceous, as long as the pedicel; fr. black, smooth. Hudson Bay to Alaska, south to N. Minn. B.B. (ed. 2) 2:237.—*R. integrifolium*, Philippi. Evergreen unarmed shrub, to 3 ft.; lvs. coriaceous, lanceolate, dentate above the middle, glabrous, $1\frac{1}{2}$ -1 $\frac{1}{4}$ in. long; fls. dioecious, yellow, in pendent racemes $\frac{3}{4}$ -1 $\frac{1}{4}$ in. long; fr. small, purplish black. Chile; not hardy North. Gt. 30:1047.—*R. irriguum*, Douglas. Allied to *R. oxycanthoides*. Spiny shrub, to 10 ft., usually without bristles; lvs. 3-5-lobed, $1\frac{1}{2}$ -2 $\frac{1}{2}$ in. broad; fls. whitish, the peduncle exceeding the bud-scales; sepals nearly twice as long as tube; stamens about as long as petals; fr. smooth. Brit. Col. to Ore., Mont., Idaho. Has been confused with *R. cognatum*, *R. divaricatum*, and *R. inerme*, which see.—*R. japonicum*, Maxim. Allied to *R. bracteosum*. Shrub, to 6 ft.; branchlets hairy; lvs. cordate, 5-lobed, pubescent and glandular beneath, to 6 in. broad; fls. greenish or brownish, tomentose and glandular, in upright racemes to 8 in. long; bracts linear; fr. black, smooth. Japan.—*R. latifolium*, Jancz. Allied to *R. petraeum*. Unarmed shrub, to 6 ft.; lvs. 3-5-lobed, with acute lobes, glabrous or glandular-hairy, to 7 in. broad; fls. in racemes to $3\frac{1}{2}$ in. long, blood-red, campanulate; fr. red, rather large. Japan, Manchuria.—*R. laurifolium*, Jancz. Evergreen shrub, to 6 ft.; lvs. coriaceous, ovate to ovate-oblong, crenate-serrate, glabrous, 2-4 in. long; fls. dioecious, greenish, flat; stamens and petals much shorter than sepals; staminate racemes pendulous, $1\frac{1}{4}$ -1 $\frac{1}{2}$ in. long; pistillate upright, $\frac{3}{4}$ in. long; fr. ellipsoid, $\frac{3}{4}$ in. long, pubescent, reddish. W. China. B.M. 8543. G.C. III. 55:239. Gn. 76, p. 143; 79, pp. 170, 171. J.H.S. 38, p. 54, fig. 36. Not hardy North.—*R. laxiflorum*, Pursh. Allied to *R. glandulosum*. Unarmed procumbent shrub; lvs. deeply 5-lobed, slightly pubescent beneath, 2-4 in. broad; racemes upright-spreading; sepals longer, pubescent, but not glandular; fr. dark purple, bloomy, glandular. Alaska to N. Calif. Var. *coloradense*, Jancz.=*R. coloradense*.—*R. lentum*, Cov. & Rose.—*R. montigenum*.—*R. leptanthum*, Gray. Spiny slender shrub, to 4 ft.; branchlets slightly pubescent; lvs. usually truncate, deeply 3-5-lobed, glabrous or pubescent, $\frac{1}{4}$ - $\frac{3}{4}$ in. broad; fls. 1-3, white, tinged with pink; calyx-tube cylindric; sepals reflexed; fr. black, lustrous. Colo., Utah, New Mex. and Ariz. Gt. 53, p. 409. Graceful small shrub. Var. *quercetorum*, Jancz.=*R. quercetorum*.—*R. longe-racemosum*, Franch. Allied to *R. petraeum*. Unarmed shrub, to 10 ft.; lvs. cordate, 3-5-lobed, with acute or acuminate lobes, glabrous, to 6 in. broad; racemes pendulous, to 12 in. long, thinly set with greenish or pinkish fls.; calyx-tube broadly campanulate; sepals upright; bracts oval, half as long as the slender pedicels, persistent; fr. black, edible. W. China. Var. *Wilsonii*, Jancz. Young branchlets red; racemes shorter; fls. salmon-red. Cent. China.—*R.*

Viridum, Hook. f. & Thoms. Allied to *R. alpinum*. Unarmed shrub; branchlets glabrous, red; lvs. 3-5-lobed, with obtusish lobes, glabrous or nearly so, glandular, to 2 in. broad; fls. dioecious, dark purple, in upright racemes, the staminate 1-2 in. long, the pistillate shorter; fr. black, glabrous. Himalayas, W. China.—*R. malvaceum*, Smith (*R. sanguineum malvaceum*, Loud.). Allied to *R. sanguineum*. Unarmed shrub; lvs. rough above, grayish tomentose and glandular beneath; fls. pink or purple, smaller, white-pubescent and glandular; tube longer than the sepals; fr. viscid-pubescent. Calif.—*R. Marshallii*, Greene. Allied to *R. Lobbii*. Spiny shrub with puberulent branchlets; lvs. deeply cordate, 3-5-lobed, glabrous, 1-1½ in. wide; fls. solitary, large, purplish; sepals ½-¾ in. long; stamens slightly longer; petals salmon-pink; fr. purplish black, prickly. Calif.—*R. Maximowiczii*, Batal. Allied to *R. alpinum*. Shrub, to 10 ft.; branchlets pubescent; lvs. slightly 3-5-lobed, middle lobe much longer, or undivided and ovate, pubescent on both sides, 1½-4 in. long; fls. dioecious, in upright racemes 1-2 in. long; fr. glandular-hairy, red. N. W. China.—*R. Menziesii*, Pursh (*R. subvestitum*, Hook. & Arn.). Allied to *R. Lobbii*. Spiny shrub, to 6 ft.; branchlets pubescent and bristly; lvs. deeply 3-5-lobed, pubescent and glandular beneath, 1-2 in. broad; fls. purple, with white petals; stamens as long as the sepals, with ovate-lanceolate anthers; fr. glandular-bristly. Ore. to Calif. G.C. III. 45:242. R.H. 1908, p. 31.—*R. Mejeri*, Maxim. Allied to *R. petraeum*. Unarmed shrub, to 10 ft.; lvs. usually 5-lobed, with acutish lobes, glabrous or glandular-hairy above, to 3½ in. broad; racemes horizontal, lax, to 2 in. long; fls. purplish, nearly sessile, small, with upright sepals; fr. black, lustrous. Cent. Asia, W. China. Var. *turkestanicum*, Jancz. Lvs. obtusely lobed; racemes longer; fls. blood-red. Turkestan.—*R. mogollonicum*, Greene=*R. Wolfii*.—*R. mollis*, Howell, not Poepp.=*R. montigenum*.—*R. montigenum*, McClatchie (*R. lacustre* var. *molle*, Gray. *R. lentum*, Cov. & Rose). Allied to *R. lacustre*. Sts. bristly; lvs. pubescent and glandular; racemes few-fl'd.; fr. red, glandular-bristly, edible. Wash. to Mont., Idaho to New Mex.—*R. moupinense*, Franch. Allied to *R. petraeum*. Shrub, to 15 ft.; lvs. 3-5-lobed, with acute or acuminate lobes, sparingly glandular, otherwise glabrous, to 6 in. broad; racemes pendulous, loose, 1½-5 in. long; fls. greenish tinged with red, or red; sepals upright; fr. black, lustrous. W. China.—*R. nevadense*, Kellogg (*R. sanguineum* var. *variegatum*, Wats. *R. variegatum*, A. Nelson). Allied to *R. sanguineum*. Unarmed shrub; lvs. thin, 3-5-lobed, sparingly pubescent or glabrous; fls. smaller, rose-colored; sepals about twice as long as the tube; petals white; fr. blue, glaucous. Ore., Calif., Nev.—*R. occidentale*, Hook. & Arn. (*R. californicum*, Hook. & Arn.). Allied to *R. Roezlii*. Spiny shrub, to 6 ft.; lvs. usually 5-lobed, glabrous or nearly so, about 1 in. broad; fls. green or purplish; calyx-tube about as long as broad; sepals glabrous, except a tuft of hairs at the apex; stamens as long as sepals; fr. prickly. Cent. Calif.—*R. orientale*, Desf. Allied to *R. alpinum*. Unarmed shrub, to 6 ft.; young growth glandular-viscid; lvs. lustrous above, pubescent beneath; fls. dioecious, greenish, tinged with red, glandular, in upright racemes 1-2 in. long; fr. red, pubescent. S. E. Eu., W. Asia. B.M. 1583 (as *R. resinosum*).—*R. palouense*, Elmer=*R. cognatum*.—*R. pulchellum*, Turcz. Allied to *R. diacantha*. Spiny shrub, to 6 ft., glabrous; lvs. truncate to subcordate, deeply 3-lobed, to 2 in. broad; fls. purplish, in upright racemes, the staminate to 2½ in. long, the pistillate shorter; fr. large, red, glabrous. N. China, Transbaikal.—*R. quercetorum*, Greene. Spiny slender shrub, sometimes bristly; lvs. 3-5-cleft, finely pubescent or usually glabrous, ¼-¾ in. long; fls. 2-3, pale yellowish with short-cylindric tube; petals shorter than the sepals, a little longer than the stamens; fr. smooth, purple. Cent. Calif. to Low. Calif.—*R. resinosum*, Pursh=*R. orientale*.—*R. robustum*, Jancz. (*R. niveum* × *R. hirtellum*). Intermediate between the parents. Spiny vigorous shrub, only the stronger shoots bristly; fls. white or pinkish, but sepals broader and shorter and filaments shorter and less pubescent than in *R. niveum*; fr. black. Origin unknown.—*R. Saundersii*, Jancz. (*R. hudsonianum* × *R. nigrum*). Intermediate between the parents; fls. pink, fading to whitish; fr. black. Originated in Ottawa.—*R. stenocarpum*, Maxim. Allied to *R. alpestre*. Spiny shrub, often bristly; lvs. cordate, 3-5-lobed, glabrous or pubescent, about 1½ in. across; fls. 1-3, short-peduncled, reddish or pale; calyx-tube campanulate, shorter than the reflexed sepals; stamens scarcely longer than petals; fr. oblong, ¾-1 in. long, glabrous or hispid. N. W. China.—*R. subvestitum*, Hook. & Arn.=*R. Menziesii*.—*R. succirubrum*, Zabel (*R. niveum* × *R. divaricatum*). Intermediate between the parents. Lvs. similar to those of *R. niveum*; fls. pink or pinkish; stamens 1½ times as long as sepals; fr. black, slightly pruinose. Originated at Gotha, Germany.—*R. tenuis*, Jancz. Allied to *R. alpinum*. Unarmed slender shrub; lvs. 3-5-lobed, lobes acute, incisely dentate, the middle one longer, glandular, to 1½ in. long; fls. reddish brown or greenish, dioecious, in upright racemes; fr. red. Cent. and W. China, Himalayas.—*R. trilobum*, Mey.=*R. Gayanum*.—*R. urceolatum*, Tausch (*R. multiflorum* × *R. petraeum*). Intermediate between the parents. Fls. reddish; fr. red. Origin unknown.—*R. utile*, Jancz. (*R. Cynosbati* × *R. Grossularia*). Intermediate between the parents. Lvs. similar to *R. Grossularia*; fls. slightly pubescent; ovary glabrous; fr. purplish, sometimes with a few spines. A more detailed description will be found under the name of "Mountain" in G.F. 9:456. It originated with the Shakers of Lebanon, N. Y.—*R. variegatum*, A. Nelson=*R. nevadense*.—*R. viburnifolium*, Gray. Evergreen, unarmed, aromatically scented shrub, to 8 ft.; branchlets glandular; lvs. ovate or oval, obtuse, coarsely toothed, glossy above, resinous-dotted beneath, ¾-1½ in. long; fls. dark pink, in upright racemes; fr. ovoid, red. Low. Calif., Santa Catalina Isl. B.M. 8094.—*R. villosum*, Gay, not Nutt.=*R. Gayanum*.—*R. Vilmorinii*, Jancz. Allied to *R. alpinum*. Unarmed shrub, to 6 t.; lvs. 3-5-lobed with obtuse or acutish lobes, glandular above, about 1 in. broad; fls. dioecious in short upright racemes, greenish or tinged reddish brown; fr. small, black, glabrous or glandular. W. China.—*R. Warsce-*

wiczii, Jancz. Allied to *R. rubrum*. Unarmed shrub, to 6 ft.; lvs. slightly 3-5-lobed, slightly pubescent below, to 4 in. broad; fls. larger, pinkish, in pendent racemes 2 in. long; fr. larger, purplish black, very acid. E. Siberia.—*R. Watsonianum*, Koehne (*R. ambiguum*, Wats., not Maxim.). Allied to *R. pinetorum*. Spiny shrub, upright or ascending; branches glandular, not bristly; lvs. deeply 3-5-lobed, sparingly pubescent on the veins, 1-2 in. broad; fls. pinkish, pubescent; petals white, one-fourth shorter than sepals; stamens as long as petals; fr. greenish, prickly. Wash.—*R. Wolfii*, Rothr. (*R. mogollonicum*, Greene). Allied to *R. sanguineum*. Unarmed shrub, to 10 ft.; lvs. 3-5-lobed, pubescent on the veins and glandular beneath, 2-3½ in. broad; fls. greenish white, in upright long-stalked racemes, 1-1½ in. long; fr. black, bloomy, glandular-bristly. Colo., Utah, New Mex., Ariz. B.M. 8120.—*R. wollense*, Bean=*R. Culverwellii* var. *wollense*. ALFRED REHDER.

RÍCCIA (P. F. Ricci, Italian nobleman, patron of the botanist Micheli). *Ricciaceae*. *Riccia fluitans*, Linn., is one of the few flowerless or cryptogamous plants in cultivation aside from the ferns, mushrooms and selaginellas. It has been listed by one specialist in aquatics presumably for the benefit of students of botany. It is not generally advertised among aquarium plants. The form used in aquaria is the floating sterile state; the fruiting state (*R. canaliculata*, Hoffm.) grows on the ground in muddy places. In this family of plants the plant-body is a thallus (i. e., a green, flattish body not differentiated into root, stem and leaves). The thallus of *Riccia* spreads out in green patches which are at first radiately divided, and the center of the plant often decays quickly. *R. fluitans* is distinguished from other species by the linear dichotomous thallus, with the capsule protuberant from the lower surface.

RICCIOCARPUS (*Riccia-fruited*). *Ricciaceae*. The single formerly recognized species of this genus, *R. natans*, Corda, is offered abroad as an aquarium plant. It is a small floating plant, consisting of a single spatulate frond about ½ in. or less long, more or less cleft or cordate at the larger end or dichotomously branched, from the under side of which many root-like bodies are emitted. It is widely distributed over the earth. From *Riccia*, the plant is distinguished by technical characters of archegonia and antheridia, and it has been united with that genus by some authors. A second species has recently been added to the genus, *R. velutinus*, Steph., from W. Amer.; it appears not to have been listed for cultivators.

RICE: *Oryza*. **R. Flower:** *Pimelia*. **R., Mountain:** *Oryzopsis*. **R. Paper:** The Chinese rice paper is made from *Fatsia japonica*, which see.

RICHÁRDIA: *Zantedeschia*.

RICINOCÁRPOS (from *Ricinus* and Greek for fruit). *Euphorbiaceae*. Tropical shrubs sometimes cult. for ornament; glabrous to stellate-tomentose, often heath-like: lvs. alternate, simple, entire, linear to lanceolate; stipules none; fls. small, solitary or clustered, rarely apetalous; calyx imbricate; stamens numerous; ovules 1 in each cell. Fifteen species of Austral. *R. pinifolius*, Desf., NATIVE JASMINE, glabrous, lvs. linear; and *R. speciosus*, Muell. Arg., tomentose, lvs. oblong, have occasionally been cult. J. B. S. NORTON.

RICINODÉNDRON (from *Ricinus* and Greek for tree). *Euphorbiaceae*. Tropical trees with economic uses, but rarely cult.: juice milky; lvs. alternate, long-petioled, palmately 3-9-foliolate, stipulate; fls. small, in loose panicles; calyx imbricate; petals connate or free; stamens numerous, filaments free; ovules 1 in each cell. Three or four species in Afr. *R. Heudelotii*, Pierre, is a prominent plant in W. Afr. J. B. S. NORTON.

RÍCINUS (the name in classical languages applied to the castor bean seed and to a similar tick). *Euphorbiaceae*. Plants cultivated for the oil of the seed and as tall annuals for the bold and ornamental foliage; useful for screens.

Herbaceous, or becoming small trees in the tropics, glabrous, or rarely subspinose, branching repeatedly from below the fl.-clusters: lvs. large, alternate, petiole, palmately 5-12-lobed, the lobes dentate or serrate; petiole with conspicuous glands: fls. monœcious, in terminal or apparently lateral racemes or subpaniculate, without petals or disk;

3409. Fruit of castor bean, showing the capsules inside. (×1)

calyx 3-5-parted, valvate; staminate fls. short-pediceled, in the upper part of the raceme; stamens many, filaments much branched, no rudimentary pistil; pistillate fls. below, longer-pediceled; styles 3, plumose: caps. generally covered with soft spinose processes, 3-celled, 1 ovule in each cell, explosively separating into 2-valved cocciæ when ripe; seeds ovoid, with a large caruncle; seed-coat crustaceous, variously marked and colored; endosperm fleshy and oily; cotyledons broad, cordate or ovate.—Hundreds of forms are known, many so well marked as to deserve specific rank, were they not so thoroughly connected by intermediate forms and hybridizing so freely when brought together. Most botanists follow Mueller (De Candolle's *Prodromus*, vol. 15, pt. 2:1061, 1866) in referring them all to the one species. Probably a native of Afr., but now cult. and wild in most tropical and temperate lands.

Castor beans have been cultivated from the earliest times for the oil of the seeds. The Hebrew name indicates that perhaps this is the plant referred to in the Book of Jonah as a gourd. The oil (castor-oil, *Oleum Ricini*) is used in medicine and in the arts and in some places in the preparation of food. The seed contains a poisonous principle, ricinin. For the cultivation of castor beans as a field crop, see "Cyclopedia of American Agriculture," 2:229. The chief castor-oil-producing region is in India, but some is grown in the United States, especially in Oklahoma.

3410. *Ricinus communis*.

3411. Clump of *Ricinus communis*.

Ricinus is one of the best plants for giving a tropical effect in beds and borders or planted singly. It thrives in rich well-drained sandy or clay loam, but is not suited for stiff clay or very sandy soil. For garden decoration the seeds may be planted in May where they are to grow, or sown indoors in small pots, two or

three seeds each, in early spring, and after germination thinned to one plant to a pot. As they grow they may be transferred to larger pots and finally planted out. The castor beans have practically no insect or fungous enemies of importance. They have been erroneously supposed to keep away moles and malaria.

communis, Linn. **CASTOR BEAN. CASTOR-OIL PLANT. PALMA CHRISTI.** Figs. 3409-3411. Three to 15 ft. high when grown as an annual, 30-40 ft. in the tropics. The various varieties are distinguished by the size, color, and outline of the plant and lvs., the glands of the petiole, the number and size of the processes on the caps., the shape of the cotyledons, and especially the size, form, color, and markings of the seed, which show variations sufficient to distinguish individual plants, and even separate branches of the same plant. So far as the forms commonly in cult. are concerned, the species may be subdivided as follows:

A. *Markings of seed-coat marbled, distinct from the ground-color; seed less than twice as broad as thick; cotyledons elliptical or oblong, nearly truncate at base, petiole-glands various.*

B. *Seeds small to medium, brown-marked; petiole-glands flat, not projecting.* This includes most of the oil-producing varieties and the typical *R. communis* (illustrations, variety not designated: B.M. 2209. A.G. 17:363. F.W. 1868:98. Gn. 1, p. 541; 9, p. 460. Gt. 24, p. 281; 31, p. 20. Mn. 7, p. 223. R.H. 1861, pp. 9, 10. V. 2:224); also the following varieties: *giganteus* (lividus, Willd., *pruinösus*, ?), glaucous foliage (V. 16:148); *arboreus*; *major*; *minor*; *viridis*, sts. and lvs. green; *inermis*, fr. smooth; *purpurascens*; *africanus*; *elegantissimus*; *speciosus*.

BB. *Seeds medium to large, reddish to reddish-brown; glands of petiole large, projecting; plant usually red; st. often more hollow, short-lived and early-fruited.* The typical form is var. *sanguineus* (Obermänni, *lividus*, Jacq.?) (Gn. 5, p. 349. R.H. 1858, pp. 602, 603); *macrocarpus* (V. 16:148); *purpureus* (*tricolor*); *atropurpureus*; *sanguinolentus*; *macrophyllus*?; *macrophyllus purpureus*; *pulcherrimus*.

BBB. *Seeds as in BB, but dark brown to black; otherwise as in B.* *Bourboniensis*, and its vars. *nanus* and *arboreus* (V. 16:148).

AA. *Markings of seed-coat rather straight, slightly raised above the ground-color and distinct from it; seeds*

medium size, more than twice as broad as thick; cotyledons ovate, rounded at the base, glands small, flat; foliage red to almost black. Contains var. *Gibsonii*, dwarf, dark red with metallic luster; *Gibsonii coccinea*; *Gibsonii mirabilis*, bright carmine fr.; *cambogensis*, very dark foliage; *hybridus panormitanus*, large, dark and glaucous, a cross with *zanzibarensis* and *philippinensis*.

AAA. Markings of seed-coat of fine bright red mottling, diffusing into the ground-color (gray or brown in some of the hybrids); seeds large, flat; cotyledons cordate; glands many, large, projecting at the apex and decurrent; plants large, generally without much red color, if any. Contains var. *zanzibarensis* (A.G. 16, p. 383. G.C. III. 14:783. Gn. 44, p. 563. Gt. 43, p. 69. I.H. 41:100) and its varieties, which seem to be crosses with some of the previous groups. (Gt. 44, p. 77.)

Other names in the trade, but not classified above, are: *cæruleus*, *Bismarckiana*, and *instignis*.

J. B. S. NORTON.

RIGIDÉLLA (Latin, somewhat rigid; referring to the pedicels, which after the petals fall become erect and stiff). *Iridaceæ*. Half-hardy bulbous plants allied to *Tigridia* and useful for planting in the garden.

Leaves broad, plicate, with channeled petiole: fls. fugitive, bright red, pedicelled; perianth-tube none; segms. very unequal, outer oblong, connivent in a cup in the lower third, then spreading or reflexed; inner very small, erect, ovate, with a narrow claw.—About 3 species, Mex. Distinguished from *Tigridia* by the very small inconspicuous ovate and erect inner perianth-segms., those of *Tigridia* being larger, fiddle-shaped and spreading.

flammea, Lindl. St. 3–5 ft. high: lvs. broadly equitant, plicate and sheathing the st. below: fls. in terminal fascicles, between the 2-valved spathe; peduncles recurved but becoming erect in fr.; perianth 3-foliate, the limb concave and revolute, bright scarlet striped black at the throat, spirally twisted after anthesis: caps. papery, 3-valved at the apex. Mex. B.R. 26:16. H.U. 2, p. 44.

immaculata, Herb. St. 2–3 ft. high, forked: lower lvs. narrowly lanceolate, acute, about as tall as the scape: fls. bright crimson, not marked with black; perianth-segms. acute, undulate, recurved. Mex. B.R. 27:68. F.S. 5:502; 21:2215 (fls. brick-red).

F. TRACY HUBBARD.†

RINDÈRA (named after Dr. A. Rinder, the discoverer of the first plants of this genus). *Boraginaceæ*. Perennial herbs, erect, canescent-pubescent, scabrous or glabrous, base often cespitose: sts. simple or sparingly branched: lvs. alternate, narrow: cymes terminal, corymbose or paniculate-racemose, without bracts; fls. pedicelled; calyx 5-parted, lobes narrow; corolla tubular-funnel-shaped; lobes 5, imbricate, broad or oblong, erect or somewhat spreading; stamens 5; ovary 4 distinct lobes: nutlets 4. About 10–15 species, S. Eu., W. and Cent. Asia. *R. umbellata*, Bunge. St. erect, 1–2 ft. high: basal lvs. tufted, evergreen, oblong to ovate-lanceolate, long-petioled; cauline lvs. lanceolate with a winged petiole or sessile, entire, gray-pubescent: fls. reddish yellow or dark brown; calyx densely woolly; corolla-lobes erect, oblong: nutlets ovate-orbicular, broadly winged. Hungary and Servia. G.C. III. 42:226.

RITÁIA (named after Mr. Rita of the Khasia Commission). *Orchidaceæ*. Epiphytic orchid, rare in cult.: st. much and subdichotomously branched, densely clothed with scarious sheaths: branches short and bearing a terminal sheathed, 1–2-flid. peduncle: lf. fleshy, lanceolate, jointed to the axis at the end of a branch: fls. small, puberulous; lateral sepals broad-based, adnate to the foot of the column; lip adnate by its margins to the column. One species, Himalaya. Now referred to

Ceratostylis. *C. himaláica*, Hook. f. (*Ritáia himaláica*, King & Pantl). Sts. pendulous with a solitary lf. and a single terminal peduncle: lf. fleshy, linear-oblong, apex obliquely notched: fls. 1, occasionally 2, pale yellow, pubescent outside; dorsal sepal ovate-lanceolate, lateral sepals broader, abruptly acuminate; petals linear, about as long as the sepals; lip fleshy, not lobed.

F. TRACY HUBBARD.

RIVINA (named after A. Q. Rivinus, professor of botany, at Leipzig, 1691–1725). *Phytolaccaceæ*. Erect

3412. *Rivina humilis*. (× 1/3)

herbs, shrubby at base, suitable for the warm-house and also useful outdoors as a summer annual.

Leaves alternate, slender-petioled, ovate, ovate-lanceolate or cordate-ovate; stipules minute and caducous: infl. racemose, axillary or rarely terminal; fls. small, perfect; perianth 4-

parted; stamens 4: berry red, pea-like.—Species 3 (Walter, Engler's Pflanzenreich, hft. 39), native of Trop. and Subtrop. Amer., but intro. into Asia and Afr.

humilis, Linn. (*R. lævis*, Linn.). **ROUGE PLANT**. Fig. 3412. St. with spreading branches, 1/2–2 ft. high: lvs. 1–3 in. long: racemes slender, pendulous, many-fld., as long as the lvs.; fls. white, 1–1 1/2 lines long; calyx pale rose: fr. 1–1 1/2 lines long. S. Fla. B.M. 1781. V. 5:75. S.H. 2:111. Gn. 22, p. 68.—Variable.

F. TRACY HUBBARD.

ROBÍNIA (after Jean and Vespasien Robin, herbals to the king of France in the sixteenth and seventeenth centuries). *Leguminosæ*. **LOCUST**. Ornamental woody plants grown chiefly for their handsome white, pink, or purple flowers and the graceful foliage.

Deciduous trees or shrubs: branches without terminal bud, often with stipular spines: lvs. alternate, stipulate, odd-pinnate, with stalked entire stipellate lflets: fls. slender-pedicelled, in axillary racemes; calyx campanulate, 5-toothed, slightly 2-lipped; corolla papilionaceous, with short-unguiculate petals, standard large, rounded, turned back, scarcely longer than wings and keel; 9 stamens connate, 1 free or partly free: pod oblong to linear, flat, several-seeded, dehiscent.—About 15 species in N. and Cent. Amer.

The locusts are all handsome shrubs and trees with bright green and graceful pinnate foliage and showy white, pink, or purple papilionaceous flowers in usually pendulous or nodding racemes followed by pods attractive in some species by the dense covering of purple hairs. *R. Pseudacacia* and *R. viscosa* are hardy as far north as Ontario, and most other cultivated species as far north as Massachusetts. They are not particular as to the soil and they do well even in poor sandy soil and dry locations. They stand transplanting well and grow rapidly while young. Some species, particularly *R. hispida*, spread by suckers and may for this reason become a nuisance in lawns and mixed groups. *R. Pseudacacia*, on account of its heat- and drought-resisting qualities, together with its ornamental merits, has become a favorite street tree for cities, particularly in Europe; in this country it is now not so much planted, as it is liable to the attacks of the borer and therefore short-lived; it stands severe pruning well. Propagation is by seeds sown in spring and germinating readily; they

may also be increased by suckers and some, particularly *R. hispida*, grow readily from root-cuttings. Varieties are usually grafted, either on young seedling stock in the house or outdoors in spring or on pieces of root in the greenhouse; some dwarf forms, as *R. Pseudacacia* var. *Réhderi* are propagated by division, and other varieties, particularly var. *Bessoniana*, by cuttings of mature wood in fall; some varieties, as var. *Decaisneana* and var. *monophylla*, may be raised from seed, as a large percentage comes true.

A. Fls. white (light pink in one variety): branchlets glabrous or slightly pubescent: pod smooth.

1. *Pseudacacia*, Linn. FALSE ACACIA. BLACK LOCUST. YELLOW LOCUST. Fig. 3413. Tree, to 80 ft., with deeply furrowed dark brown bark and prickly branches: lfts. 7-19, oval or elliptic, rounded or truncate and mucronate at the apex, glabrous or slightly pubescent while young, 1-2 in. long: fls. white, very fragrant, about $\frac{3}{4}$ in. long, in pendulous puberulous racemes 4-5 in. long: pod linear-oblong, reddish brown, 3-4 in. long. May, June; fr. in Aug. and Sept., remaining on the branches during the winter. Pa. to Ga., west to Iowa, Mo., and Okla., often naturalized elsewhere; probably the only American tree which has become extensively naturalized in Eu. S.S. 3:112, 113. F.E. 32:393. Gn. 61, p. 61. G.M. 45:513. H.W. 3:58, p. 104.—Many varieties are in cult., of which perhaps the following are the best known. Var. *umbraculifera*, DC. (var. *inermis*, Kirchn., not DC.). Forming a dense subglobose head, with unarmed branches: rarely flowering. Much used in Eu., when grafted high, in formal plantations and as a small street tree. M.D.G. 1903:630. Var. *Bessoniana*, Nichols., with slenderer branches forming a less dense head, and var. *Réhderi*, Kirchn., a low subglobose form, usually grown on its own roots (G.W. 2, p. 217), are forms of var. *umbraculifera*. Var. *stricta*, Loud., is a broadly pyramidal form. Var. *pyramidalis*, Pépin (var. *fastigiata*, Nichols.), is a narrow pyramidal or columnar form with unarmed branches. Gt. 6:190. I.H. 6, p. 20. B.H. 14, p. 27. F. 1874, p. 242. G.C. III. 41:151. Var. *pendula*, Loud., with somewhat pendulous branches. Var. *tortuosa*, DC. A slow-growing form with short twisted branches sometimes pendulous at the tips. G.W. 2, p. 218. Var. *Ulriciana*, Reuter. With spreading slightly pendulous branches and large drooping lvs. Var. *inermis*, DC. Branches unarmed: lvs. dark green: habit like the type. Var. *monophylla*, Carr. Lvs. simple or partly with 3-7 large lfts. R.H. 1860, pp. 630, 631. Var. *bullata*, Koch. Lfts. crowded, more or less bullate. Var. *crispa*, DC. Lfts. undulate or crisped. Var. *amorphifolia*, Loud. (var. *mimosæfolia*, Hort.), with narrow, oblong lfts. Var. *dissecta*, Nichols. Lfts. linear. R.H. 1875, p. 379. Var. *aurea*, Kirchn. Foliage yellow. Var. *purpurea*, Dipp. Young foliage purple. Var. *semperflorens*, Carr. Flowering during the whole summer. R.H. 1875:191. Var. *Decaisneana*, Carr. Fls. light rose-colored. R.H. 1863:151. F.S. 19:2027. I.H. 12:427. Gn. 9:36; 34, p. 174. G.Z. 9:160. G.M. 56:971.—This is the largest species of the genus and its hard and strong, close-grained timber is much esteemed for its strength and its durability in contact with the soil.

AA. Fls. pink or purple.

B. Plant glabrous or merely pubescent or tomentose: lfts. usually less than 15.

c. Pod smooth.

2. *Boyntonii*, Ashe. Shrub, to 10 ft., unarmed: branchlets glabrous or minutely pubescent at first: lfts. 7-13, elliptic to oblong, obtuse, soon glabrous, $\frac{3}{4}$ -1 in. long: racemes 8-12-fld., on spreading or ascending peduncles; corolla rose-purple or pink with white, $\frac{3}{4}$ in. long: pod glabrous. May, June. N. C. and Tenn. to Ga. and Ala.

cc. Pod hispid or glandular hairy.

3. *Kelsey*, Bean. Shrub, to 10 ft.: branches with slender prickles; branchlets glabrous: lfts. 9-11, oblong-lanceolate, acute, rounded at the base, glabrous, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: racemes 5-8-fld.; rachis and pedicels sparingly glandular-hairy; calyx finely pubescent, with or without glandular hairs; corolla rose-colored, 1 in. long: pod oblong, densely covered with purple glandular hairs, 1 $\frac{1}{2}$ -2 in. long. May, June. N. C. B.M. 8213. G.C. III. 44:427; 47:391; 58:72. J.H. S. 36, p. 133, fig. 134. G. 33:461, 463. M.D. 1910, p. 101. Addisonia 1:3.—Very handsome and graceful; the purple frs. are also attractive.

3413. *Robinia Pseudacacia*. ($\times \frac{1}{2}$)

4. *Elliotii*, Ashe (*R. hispida* var. *rosea*, Elliott). Shrub, to 5 ft.: branches with short spines; young branchlets grayish or whitish tomentose: lfts. 11-15, elliptic, grayish pubescent beneath, $\frac{3}{4}$ -1 in. long: racemes 5-10-fld.; peduncles, pedicels, and calyx grayish pubescent; corolla rose-purple or purple and white: pod linear, hispid. May, June. N. C. to Ga.—A very handsome species easily distinguished by the dense grayish pubescence without glands or bristles.

BB. Plant more or less bristly or glandular-pubescent or viscid: pod hispid.

c. Peduncles and branchlets hispid or the latter sometimes glabrous: lfts. usually less than 15.

5. *hispida*, Linn. (*R. rosea*, Marsh.). ROSE ACACIA. Fig. 3414. Shrub, 1-3 ft., rarely higher: st., branchlets, and peduncles and often the petioles hispid: lfts. 7-13, suborbicular to oval, obtuse and mucronate, glabrous or nearly so, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. rose-colored or pale purple, 1 in. long, in short, 3-5-fld. racemes: pod rarely developed, densely hispid, few-seeded. F.S.R. 2, p. 57. J.H. III. 53:183. G. 4:499. Var. *macrophylla*, DC. (var. *inermis*, Kirchn.). Branchlets and petioles nearly destitute of bristles: lfts. and fls. often somewhat larger. Gn. 77, p. 268. G.M. 45:512.—This species spreads much by suckers, particularly in sandy soil; sometimes grafted high to form a small standard and as such displaying its large fls. to greater advantage.

6. *nana*, Spach (*R. hispida* var. *nana*, Elliott). Shrub, about 1 ft. high, in cult. sometimes higher: sts.

hispid, branchlets, petioles, and peduncles only pubescent or more or less hispid: lfts. 9–15, elliptic or ovate, acute, narrowed or rounded at the base, appressed-pubescent beneath, at least while young, $\frac{1}{2}$ –1 in. long: racemes 3–6-fl.; corolla $\frac{3}{4}$ in. long, purple with white: pod oblong, hispid. May, June. N. and S. C.—This species usually fruits profusely, while the preceding species never or very rarely fruits.

cc. *Peduncles and branchlets glandular-hairy or viscid: lfts. usually more than 15.*

d. *Branchlets and peduncles glandular-hairy.*

e. *Rachis of lf. pubescent, glandless or nearly so.*

7. *neo-mexicana*, Gray. Shrub or small tree, to 25 ft.: branches spiny; branchlets pubescent and glandular: petioles villous; lfts. 15–21, elliptic-oblong, rounded and mucronate, silky pubescent beneath at least while young, 1–1½ in. long: racemes many-fl., dense, more or less upright; peduncle and pedicels glandular-hairy; corolla pale rose-colored or sometimes nearly white,

3414. Rose acacia.
—*Robinia hispida*.
($\times \frac{1}{2}$)

nearly 1 in. long: pod glandular-hispid, 3–4 in. long. June to Aug. Colo. to New Mex., Ariz., and Utah. B.M. 7726. S.S. 3:114. F.S.R. 2:56. Gt. 41:1385. R.H. 1895.—Valuable for its late flowering.

8. *Hóldtii*, Beissn. (*R. neo-mexicana* $\times$ *R. Pseud-acacia*). Tree, intermediate between the parents: lfts. larger than those of *R. neo-mexicana*, 1½–2 in. long, darker green and firmer than those of *R. Pseud-acacia*: racemes looser than those of the first parent; corolla light pink to rose-colored: pod with scattered stalked glands. Originated in the nursery of F. von Holdt, Alcott, Colo. Var. *britzensis*, Spaeth. A form with nearly whitish fls., originated in Spaeth's nursery near Berlin, Germany. Also *R. coloradensis*, Dode, probably belongs here.

ee. *Rachis of lf. densely covered with stalked glands.*

9. *Hártwigii*, Koehne. Shrub, to 12 ft.: branchlets, petioles, lf.-rachis, and peduncle puberulous and densely covered with stipitate glands: lfts. 13–23, elliptic to lanceolate, mucronate, grayish pubescent beneath, 1–1¼ in. long: racemes dense; calyx pubescent and glandular-hairy; corolla rosy purple, $\frac{3}{4}$ in. long: pod oblong, densely glandular-hairy, about 2 in. long. June, July. N. C. to Ala.

dd. *Branchlets and peduncles viscid.*

10. *viscosa*, Vent. (*R. glutinosa*, Sims). Tree, to 40 ft.: branches without or with small and slender spines; the dark reddish brown branchlets and usually the petioles and peduncles densely glandular-viscid: lfts. 13–25, ovate to oblong, obtuse or acute, broadly cuneate at the base, pubescent beneath or sometimes glabrous, 1½–2 in. long: racemes 6–15-fl., dense, rather upright; corolla $\frac{3}{4}$ in. long, pink; standard with a yellow blotch: pod linear-oblong, glandular-hispid,

2–3½ in. long. May, June. N. and S. C. to Ala.; naturalized elsewhere. S.S. 3:115. B.M. 560.

11. *dàbia*, Foucauld (*R. ambigua*, Poir. *R. intermedia*, Soulange-Bodin. *R. Pseud-acacia* $\times$ *R. viscosa*). Tree, intermediate between the parents, but more similar to *R. Pseud-acacia*, from which it differs in the slightly viscid, less prickly branches, in the 15–21 lfts., and in the light pink fls. Of garden origin. Var. *bélla-rôsea*, Rehd. (*R. bélla-rôsea*, Nichols. *R. viscosa* var. *bélla-rôsea*, Voss. *R. Pseud-acacia* var. *bélla-rôsea*, Cowell). Branchlets more viscid: fls. larger and deeper rose-colored. Garden origin.

R. Rúsbyi, Wooton & Standley. Nearly glabrous prickly shrub with oval or broadly oblong lfts. pubescent beneath, many-fl. racemes with the pedicels glandular-pubescent, and with smooth pods, from New Mex.; this and the 6 or 7 Mexican species are not in cult.

ALFRED REHDER.

ROBÝNSIA (derivation not known). *Leguminosæ*. Twinning shrubs, with trifoliate lvs. and elongated axillary racemes: fls. somewhat fascicled; calyx 2-lipped; corolla papilionaceous, standard somewhat rounded, sulcate at the base, wings oblong, obtuse, keel incurved, obtuse; stamens diadelphous: pod compressed, 2-valved, linear-elongate.—Two or 3 species, Mex. The genus is now usually included in *Pachyrhizus*. *R. geminiflora*, Hort., is apparently botanically unknown. H.U. 2, p. 231.

ROCAMBOLE (*Allium Scorodoprasum*, Linn.), is a humble member of the onion tribe, the underground bulbs of which are used abroad like garlic, known in America amongst the Canadian French and perhaps elsewhere. The plant is a hardy perennial, with a stem twisted spirally above and bears at the top an umbel of flowers, some or all of which are changed to bulblets. The presence of these bulblets distinguishes the plant from garlic. The species can be propagated by the bulblets, but quicker results are secured from the cloves of the underground bulbs. In mild climates, the bulbs should be planted in autumn or not later than February; in cold climates, plant in spring. In the autumn when the leaves decay, the bulbs are lifted, dried in the sun, and stored.

Rocambole is a native of Europe, the Caucasus region, and Syria. It has flat or keeled leaves, short spathe, bell-shaped six-parted perianth, and the three inner stamens broader than the others, three-cleft, and not longer than the perianth. Good seeds are rarely produced.

RÔCHEA (named after de la Roche, French botanist). Syn., *Kalosánthes*. *Crassulacæ*. Succulent shrubby plants suitable for the greenhouse.

Leaves opposite, connate at the base, oblong-ovate or lanceolate: fls. rather large, aggregated in corymbose-capitate cymes, white, yellow, rose, or red; calyx 5-parted or 5-cleft; corolla salver-shaped, the elongated claws of the petals connate with the calyx-tube, limb spreading: follicles many-seeded.—About 4 or 5 species, S. Afr.

Roches are amongst the showiest of our summer-flowering greenhouse plants, and are very easy to propagate. If plants are desired from a single root, cuttings about 4 inches long should be selected in March, and potted singly in sandy peat. The small pots should be placed near the glass, in a night temperature of 50°. Do not keep them too wet, as they are of a fleshy nature, and are liable to rot. In a few weeks, the plants will be rooted and the points may be cut out to encourage breaks. A few days after they are cut back, repot into a pot two sizes larger, using two parts fibry loam, one of sand, and one of broken charcoal, adding a sixth part of sheep-manure. After they are rooted, keep them near the glass, in a night temperature of not over 40°, when this is possible.

XCVII. A rock-garden.

When all danger of frost is past, set them outdoors on a bed of ashes in the full sun, making some provision to protect them from rainstorms, so as to prevent water lodging in the points of the shoots, which is liable to bring about conditions favorable to disease. Toward the end of September, have the plants housed in their winter quarters; all that is necessary during the winter is to keep them from freezing. In spring, the points of the shoots may be cut out again, to encourage more breaks and soon after they may receive another shift. Treat them as advised above, and when the pots are well filled with roots, they may be watered with manure-water as advised for ixoras. Rocheas may be flowered the second summer after the cuttings are struck, and after flowering the plants may be cut back to 6 inches above the pot. These cut-back plants may be shifted along, after they break, and be grown into large specimens. Fine plants of rochea may also be grown in the following manner; Take a 10- or 12-inch pot, and fill it with the compost advised above, the last 2 inches being pure sand. Insert the cuttings as thick as they can be pricked into the pot. The cuttings may be secured from a plant that has flowered. Breaks will start all over the stems of such plants, and in the fall after flowering they will be large enough to use for cuttings. In eighteen months this pot of cuttings will come in flower and will have more than doubled the number of shoots. Aphides are the only insect pest that molest the rocheas, and these may be destroyed by fumigating with tobacco in some of its forms. These plants require at all times abundance of fresh air, and if this is not given, they will be attacked by fungous disease. (George F. Stewart.)

A. Clusters usually 2-fl.

jasminea, DC. (*Crassula jasminea*, Ker-Gawl). St. subshrubby, 4-12 in. high, decumbent, branched, flowering part erect: lvs. fleshy, oblong-oval or spatulate, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. white, tinted with crimson, sessile, not fragrant, $1\frac{1}{2}$ in. long. Cape B.M. 2178. L.B.C. 11:1040.—Hybrids with *R. coccinea* are figured in A.F. 5:433.

AA. Clusters many-fl.

coccinea, DC. (*Kalosánthes coccinea*, Haw. *Crassula coccinea*, Linn.). Plant robust, shrubby, 1-2 ft. high: lvs. very closely imbricated, ovate-oblong or ovate, $1\frac{1}{2}$ - $2\frac{1}{4}$ in. long: fls. bright scarlet, $1\frac{1}{2}$ -2 in. long, fragrant, borne in summer. Cape. Gn. 46, p. 360. B.M. 495.—Showy; hybrids are in cult.

R. falcata, DC. = *Crassula falcata*.—*R. hybrida albiflora* is said to be a hybrid between *R. jasminea* and *R. odoratissima*.—*R. odoratissima*, D.C. Somewhat shrubby, 12-20 in.: lvs. connate, erect-spreading, linear-lanceolate or subulate: fls. 1 in. long, fragrant, pale yellow or cream-colored. Cape.

L. H. B.†

ROCK-GARDEN. An ornamental planting in very rocky places or in areas on which rocks have been placed for the particular purpose to make congenial conditions for certain classes of plants and also to lend interest and variety to a part of the grounds; a rockery. Figs. 3415-3419. See, also, *Alpine Plants*, Vol. I.

Nature in time will make a garden even on the broken surface of a rock, by clothing it with lichens, algae, and mosses of many exquisite forms having much variety and often striking brilliancy in coloring. If there are soil-filled cracks and pockets, then ferns and flowering plants will find a place. At low elevations, however, these flowering rock-plants are comparatively few, for soil accumulates rapidly and strong-growing herbs, shrubs, and trees, aided by favorable climatic conditions, soon cover the rock surface or furnish so dense a shade that only mosses, lichens, and ferns will thrive.

The ideal rock- or alpine gardens are within that region on mountain summits between the limits of tree-growth and the edge of perpetual snow, and in the corresponding regions toward the poles, where the plants are protected from the rigors of a long winter by

blankets of snow and are quickened into a short period of rapid growth by a comparatively low summer temperature. Here, where there are deep cool moist rock-crevices and pockets filled with fragments of broken stone and porous decayed vegetable matter, are the favorable conditions wherein the real alpine plants can multiply their neat and dainty cushions, tufts, and rosettes of dense and matted foliage and their abundance of exquisitely formed and brilliantly colored flowers. A successfully grown collection of these plants in contrast with ordinary garden flowers would be like a collection of cut gems as compared with one of rough minerals and rocks, for they have an exquisiteness of finish and depth of coloring that gives them as unique a place in the vegetable kingdom as they have in the plan of nature. Surely there are men and women who, if they knew these plants well, would be fired with an ambition to excel in their cultivation; and in so doing they may enter a comparatively untrodden path if they will limit their work chiefly to the alpine of this continent. They are represented in the New England mountain region by such species as *Arenaria grænlandica*, *Loiseleuria procumbens*, *Silene acaulis*, *Diapensia lapponica*, *Arctous alpina*, *Vaccinium cæspitosum*, *Saxifraga aizoon* var. *rivularis*, *Veronica alpina*, *Geum radiatum* var. *Peckii*, *Sibbaldia procumbens*, *Rhododendron lapponicum*, *Phyllodoce cærulea*, *Primula farinosa*, *Saxifraga oppositifolia*, *S. aizoon*, and *S. aizoides*, *Aster polyphyllus*, and *Woodsia glabella*; and in the Rocky Mountains and Pacific Coast ranges by *Erigeron uniflorus*, *E. lanatus*, and *E. ursinus*, *Actinella Brandegei* and *A. grandiflora*, *Artemisia borealis*, *A. scopulorum*, and *A. alpina*, *Senecio Soldanella*, *S. Fremontii*, *S. petraeus*, *S. uniflorus*, and *S. werneriæfolius*, *Crepis nana*, *Campanula uniflora*, *Primula Parryi* and *P. suffruticosa*, *Androsace Chamæjasme* and *A. septentrionalis*, *Gentiana prostrata*, *G. frigida*, *G. Newberryi*, *G. Parryi*, and *G. simplex*, *Phlox bryoides* and *P. cæspitosa*, *Polemonium confertum*, *Cassiope Mertensiana*, *Phyllodoce Breweri*, *Draba streptocarpa*, *D. Parryi*, and *D. nudicaulis*, *Arabis Lyallii* and *A. platysperma*, *Smelowskia calycina*,

3415. A rock-garden bordering a lawn.

Lychnis montana and *L. Kingii*, *Calandrinia pygmæa*, *Claytonia megarrhiza*, *Spraguea umbellata*, *Dryas octopetala*, *Geum Rossii*, *Saxifraga chrysantha* and *S. bryophora*, *Cystopteris alpina*, *Allopappus pygmæus*, *A. Lyallii*, and *A. acaulis*, *Omphalodes nana* var. *aretioides*, *Chionophila Jamesii*, and so on. (Not all of these names are accounted for in this work. They may be found in the current manuals of North American plants.)

The uncultivated American plants in this class are quite as numerous and attractive as are the European

species that have been long cultivated there. Here alpine plants have been but little undertaken. A very few easily grown European kinds, as *Aubrietia deltoidea*, *Achillea tomentosa*, *Campanula carpatica*, and *Arabis alba*, are offered by American nurserymen and cultivated in the open border. On a few private places small rock-gardens have been established, or advantage has been taken of favorable local conditions to cultivate some additional species, and in one or more botanic gardens considerable collections have been at times maintained, chiefly in frames. Generally what have passed for rock-gardens have been rockeries—mere piles of cobbles raised from the surface of turf or piled against dry banks in such a manner as rapidly to disperse instead of slowly conserve all soil-moisture. Even the most self-assertive weed fails to thrive in such a garden.

In general, we have a smaller rainfall, less humidity and a larger proportion of sunny days than in England, to which we must look for careful instruction in the cultivation of alpine plants. This must be regarded in the arrangement of our rock-gardens. Every precaution should be taken to secure the full advantage of rainfall and any natural water-supply, and there should

gardens and in the open borders of almost any country or city place. Persons who desire to cultivate a large collection of true alpine plants should seek a situation where favorable natural or existing conditions may be taken advantage of. Such locations are likely to be found at the seashore and in rocky and hilly regions—such regions, for example, as are chosen by many persons for summer homes. A ledge, a natural mass of boulders or an abandoned quarry will often provide them. Pockets and crevices of ledges may be cleared of unsuitable material, and if they are not deep enough to hold moisture and have an equable temperature their depth may be increased by the judicious use of wedges, bars, and explosives. Boulders can be arranged in such a manner as to secure suitable deep pockets and crevices of soil, springs can be diverted to supply a constant flow of water, underground pipes can be carried from an artificial source of supply to various points where conditions require them. However favorable the conditions are, it will be found that much can be done to advantage in different localities to meet the special requirements of different groups of plants. In such work, however, it should be kept constantly in mind that there are plants that will grow in all sorts of sur-

roundings, and that it will often be much better to seek such as are adapted to existing conditions than to go to the expense of radically modifying such arrangements.

If an artificial rockery is to be constructed, it should be borne in mind that it is not for the purpose of displaying a collection of curious rocks fantastically arranged, but to provide a place for growing a class of plants that cannot be so well grown elsewhere. It would be better never to think of securing mountain, valley and rock effects in the disposition of the material to be used, but only to think of providing many varied conditions and situations as regards exposure to sun and shade, depth of pockets and crevices, the character and depth of soils, subterranean and surface water-supply, and whether it be permanent or fluctuating. In selecting and arranging the rocks, freshly broken raw faces should not be exposed, but rather such faces as are already covered with a growth of lichens for sunny places and with mosses for shady spots. To

take full advantage of surface water, pockets and crevices should have a decidedly downward direction from the exposed surface and not be sheltered by overhanging rock. That this does not apply in all cases, those who are familiar with the habitats of rock-plants know full well. The natural habitat of *Pellaea gracilis* in the upper Mississippi bluffs is in horizontal crevices well back from the edge of the overhanging rock, where it is absolutely protected from all surface water. It finds sufficient moisture in the horizontal seams. *Pellaea atropurpurea* will grow in narrow cracks and small pockets on the face of dry limestone boulders where there can be no possible internal supply of moisture. These examples go to show that the general principles that will apply to such plants as a class will not apply to all species, and it simply gives emphasis to the importance of trying a plant under all sorts of conditions before assuming that it can not be grown. The writer remembers well an attempt to grow that most exquisite alpine flower, *Gentiana verna*, in the open border on a little pile of rocks to give it suitable drainage. It was transplanted a number of times to places where its environment appeared to be about the same, and finally a situation was secured, where, instead of barely holding its own, it increased and produced a number of its great deep blue flower-cups.

3416. A pocket in the rocks.

also be a liberal and constant artificial water-supply. It must be kept in mind, also, that at low elevations the long hot summers do not allow the period of rest that such plants require. This condition must be met by devices, methods, and locations that will retard the growth in spring, check it at an early period in autumn, and keep the plants fully dormant in winter, such as shade, mulching, and, in the case of particularly difficult plants, the protection of frames. It is essential that conditions be provided that will enable the roots to extend for a long distance, often many feet, in narrow crevices and pockets between rocks to depths where there is a uniform temperature and uniform moisture supplied by moving water, for frequent freezing and thawing and stagnant water are fatal. These cavities should be filled with such loose material as fragments of rock mixed with decayed vegetable matter, without manure, and arranged to provide for the free passage of hair-like roots, for perfect drainage and the free access of air. To provide these unusual conditions on the average private place in a large way would be so difficult and so expensive that it is not to be recommended. A small collection, comprising a few easily cultivated alpine plants and the similar rock-plants referred to in a later paragraph may, however, be successfully grown on reconstructed stone walls, on ledges, in small rock-

The importance of protection from drying and cold winds and of securing shade in many situations must not be overlooked. Sometimes advantage may be taken of an existing deciduous or evergreen tree or shrub growth, or rapid-growing varieties may be planted to make a screen. While shelters of this character are of value about the outer limits of a rock-garden, they can hardly be used for separating its smaller compartments.

3417. An isolated rock-garden under a tree, southern California.

For this purpose, slow-growing dense-foliaged evergreens with a restricted root range are best. This would include the yuccas, a few of the dwarf forms of thuya, juniperus, picea, retinispora and practically all the broad-leaved evergreens. The latter, especially the rhododendrons (of which *Rhododendron maximum* can be secured in large plants at low cost), are particularly useful owing to their habit of growth, restricted root area, and the facility with which they can be moved from place to place as desired. As these shelter-belts and groups form the background and setting of the rock-garden and are the dominating landscape feature in views from a distance, their composition and disposition is a matter of much importance. The disposition must be governed, however, by the general arrangement of the ground, but in this arrangement an agreeably varied sky-line and composition of plant forms and of shades of green should be sought for. In the composition of the background, and in the planting of the rock-garden as well, a decided character should be given to the whole and to each distinct compartment by using some few effective plants in quantity rather than a great number of varieties in small quantities. Variegated and distorted garden freaks should be excluded, for they only distract the attention from the rock-garden, the primary object. Even more inappropriate are statuary fountains and vases.

Up to this point reference has been made for the most part to distinctly alpine plants, that is, plants that are confined exclusively to the region on mountains above the tree- and shrub-line. They are the ones that will test the skill of the cultivator. There are, however, many rock-plants, that is, plants that grow naturally on rocks, or plants having a tufted, matted, and more or less persistent and evergreen foliage similar to alpenes, that can be used with them in less favorable positions in the rock-garden or in the open border. Many of such plants can be readily procured from American nurserymen and collectors. They are easy of cultivation and attractive in habit and flower. The writer would include also low-growing bulbous plants, especially such as have inconspicuous foliage. They may be planted with the low ground-covering plants to push up through them. From this list are omitted such plants as belong more properly in the wild-garden, especially such as spread rapidly by underground shoots and are likely to become a pest. (In a rockery conditions are such that it is almost impossible to extirpate deep-rooting, weedy plants, and they above all others should be rigidly

excluded.) Among desirable rock-plants may be included *Geranium sanguineum*, *G. Andrewsii*, and *G. Robertianum*, *Gypsophila muralis*, *Helianthemum vulgare*, *Helleborus niger*, *Leontopodium alpinum*, *Linaria cymbalaria*, *Lotus corniculatus*, *Lychnis viscaria*, *Papaver alpinum* and *P. nudicaule*, *Ceratostigma larpentae*, *Saponaria ocymoides*, *Veronica teucrium* and *V. rupestris*, *Arabis alpina*, *Campanula fragilis*, *Daphne cneorum*, species of *Alyssum*, *Bellis*, *Cerastium*, *Arenaria*, *Draba*, *Epimedium*, *Iberis*, *Thymus*, *Arabis*, *Armeria*, *Ajuga*, *Dianthus*, *Sedum*, *Sagina*, *Primula*, *Aquilegia*, *Saxifraga*, *Corydalis*, *Myosotis*, *Semprevivum*, *Parnassia*, *Viola*, *Hepatica*, *Opuntia*, *Houstonia*, *Anemone patens* var. *Nuttalliana*, dwarf and creeping *Campanulas*, *Cornus canadensis*, *Dicentra eximia*, *Calluna vulgaris*, *Iris cristata*, *I. verna*, and *I. pumila*, *Leioophyllum buxifolium*, *Phlox subulata*, *P. amena*, and *P. reptans*, *Saxifraga virginienensis*, *Silene pennsylvanica* and *S. virginica*, *Anemone thalictroides*, *Waldsteinia fragarioides*, *Galax aphylla*, *Asperula odorata*, low-growing ferns, mosses, and the like.

For more specific instructions as to the construction of rock-gardens and the care and propagation of rock-plants (for European conditions), see Robinson's "Alpine Flowers," London, 1870, and Sutherland's "Hardy Herbaceous and Alpine Flowers," Edinburgh and London, 1871.

WARREN H. MANNING.

The making of a rock-garden.

A rock-garden must of necessity often be "artificial" in the sense of made by man, because few gardens or grounds contain a natural rocky slope or even a natural bank upon which one might be constructed, and if they did the position may not be an ideal one. A southern slope would be too hot and dry in this climate, unless it was shaded by tall trees. A bank with a northern or northeastern aspect free from the roots of trees would suit this class of plants much better, and very attractive it can be made, especially if the bank is on the outer edge of a garden, or skirts a lawn. There is no form of gardening in which one has more opportunity to give expression to his natural taste than in the construction and planting of a rock-garden. But since all grounds or gardens do not have a natural bank or slope upon which an "open" rock-garden might be

3418. A picturesque rockwork for the wilder parts of the grounds (European).

constructed, a depressed rock-garden may be made in grounds that are perfectly level, and some of the best rock-gardens in the world are what are known as "underground," for example, the one in the Royal Botanic Gardens, Kew, London, England. Before this rockery was constructed the ground was perfectly level. A cutting was begun at one entrance, at first shallow,

but gradually deepening till a depth of some 6 or 7 feet was reached, and an average width of about 10 feet at the bottom. All the soil taken out was placed on the top of the slopes, thus still further increasing the height. The cutting was made in a winding manner, not formal or zigzag, but in such a form that when completed, not only would a variety of aspects be secured to suit the requirements of different plants, but each turn should seem to possess a peculiar charm of its own. The whole cutting is perhaps some 200 yards in length. The rocks are placed in the banks in as natural a manner as it would seem possible to place them; now they stand out boldly, almost perpendicular with the edge of the path, then again they recede into hollow recesses. There are not too many rocks, nor yet too few. In one place a cascade falls over the rocks into a small pool which not only provides a habitat for aquatic and bog-plants, but also adds greatly to the beauty of the rockery. For the convenience of the public, a broad gravel path runs through the whole rockery. Rhododendrons and other shrubs are planted on top of the banks in groups, and not in straight lines, while behind these, for protection and shade, are planted pines and other conifers, as well as some deciduous trees. The rocks were placed in most cases so as to form "pockets" of good size into which the plants could be placed, and the soil made in the pocket to suit the requirements of the different plants. With such a variety of aspects and conditions, this rockery is able to accommodate one of the largest collections of alpine and rock-plants in the world. Deep carpets of mossy saxifrage, aubrietia, arabis, cerastium, sedum, and the like, hang over projecting ledges of rocks, while in fissures and holes in the rocks are growing those dainty rosette-making saxifrages, *S. longifolia*, *S. Cotyledon*, *S. crustacea*, and *S. cæsia*, as well as the charming androsaces. In the deeper recesses of the rockery are to be found the large-leaved saxifrages, such as *S. crassifolia*, *S. ligulata*, *S. Stracheyi*, and *S. purpurascens*. Quite at home and in suitable positions are alpine primulas, auriculas, and cyclamens. There are Iceland poppies, Himalayan poppies (*Meconopsis Wallichii* and *M. nepalensis*), gentians from the tiny blue *Gentiana verna* to the tall *G. septemfida*, and many kinds of *Hosta*, *Fritillaria*, *Erica*, *Epimedium*, *Cypripedium*, *Orchis*, *Lilium*, *Erythronium*, *Allium*, *Alyssum*, *Ajuga*, *Achillea*, *Armeria*, *Sagina*, *Sempervivum*, and creeping *Veronica*, besides other plants too numerous to mention. Particularly prominent positions, as on top of the rocks, or at a turning point in the path, are occupied by some stately plant, such as *Rheum palmatum*, *Acanthus mollis*, or *Gunnera manicata*, or *G. chilensis*, while foxgloves, ver-

bascums, and such plants would fill up the recesses in the shrubs on the top of the rockery. One end of the rockery beneath the shade of overhanging trees is devoted to hardy ferns, which grow with wonderful luxuriance. With the variety of rare and interesting plants, together with the artistic yet natural appearance of the whole rockery, a more beautiful place it would be difficult to conceive.

In 1898, the writer built a rock-garden in the Botanic Gardens of Smith College, Northampton, Massachusetts, somewhat after the pattern of the one at Kew, but on a very much more limited scale. (Fig. 3419.) The position chosen (the only one available) is near the outskirts of the garden proper, on what was formerly a grassy southern slope. A cutting was made through the slope in much the same manner as the one at Kew, but to secure good northern aspects the soil was all banked on the southern side. The path, which is quite level, varies in width from 3 to 6 feet. The height of the banks in which the rocks are placed ranges from 2 feet at the entrances to some 8 or 10 feet at the highest point. For rocks, large water-worn boulders collected in the vicinity were used. One shaded recess, with a northern aspect, is devoted to native ferns, which at the present time, 1916, comprises some forty species. The whole rockery outside is banked with flowering shrubs, and on the southern bank outside are planted some trees, chiefly catalpas, for the purpose of shading the southern aspect of the rockery, as well as for ornament. Water is laid on so that the plants might not suffer in dry weather. The writer has not been successful with alpine primulas, mossy saxifrages, tufted gentians and several other subjects which delight in a cool, moist climate, perhaps from his not having provided the ideal conditions for such plants, but more probably due to our extremes of climate. Still there is a large variety which does well here. The writer has found most of the low-growing veronicas, sedums, sempervivums, arabises, alyssums, achilleas, alsines, erysimums, aquilegias, campanulas, stellarias, pachysandras, the beautiful shrubby little *Daphne Cneorum*, and many others, do very well in the more sunny or southern aspects of the rockery, while on the northern aspects cerastiums, iberises, ajugas, Iceland poppies, rosette and large-leaved saxifrages, moss pinks, epimediums, herniarias, arenarias, cardamines, armerias, dianthus, native orchises, cypripediums, and many other plants do well. On the top of the rockery, to fill in recesses in the shrubbery, are planted foxgloves, verbasums, and tall veronicas, while at conspicuous points are planted clumps of *Bocconia cordata*, *Buphthalmium speciosum*, *Aruncus sylvestris*, or any herbaceous plant which looks well as an

isolated specimen. In among the plants in irregular colonies are planted hardy bulbs, such as crocuses, scillas, ornithogalums, narcissi, snowdrops, chionodoxas, and grape hyacinths; these come up the first thing in the spring and blossom before the other plants get well started into growth, and are a decided acquisition to a rockery.

Almost all alpine plants may be readily propagated by seed, cuttings, or division of the plants. A good plan is to sow the seeds in 4-inch pots early in February in a finely prepared light soil, and place the pots in a moderately warm greenhouse; here they soon germinate, and as soon as large enough to handle they are transplanted either into other pots similarly prepared, or into small shallow boxes. They grow vigorously through the early spring months, and by the first of

3419. Entrance to the sunken or "underground" rock-garden.—Botanic Gardens, Smith College, Northampton, Massachusetts.

May they may be planted out permanently. Seeds may also be sown in a shaded frame in spring and the plants transferred to the rockery in autumn.

In planting a newly made rock-garden, it is a mistake to plant too thickly. Each plant should be given sufficient space for a reasonable growth, and to show its true character. Compact-growing and tufted plants may be planted closer than those of a spreading habit. All variegated-leaved varieties and plants having an aggressive habit or that cannot easily be kept within reasonable limits should be rigorously excluded from a rock-garden. The whole rock-garden should be replanted and fresh soil placed in the pockets about every four or five years. In dry weather a thorough watering should be given at least once in two days, and, as in other parts of a garden, weeds will insinuate themselves wherever they can gain a foothold; these, of course, should be removed as soon as they appear. In winter, the plants in the most exposed positions, such as those which overhang ledges of rocks, should be protected by branches of hemlock or pine laid lightly over them, and a light covering of half-decayed leaves or manure placed between most of the plants, especially on a southern exposure, protects them from excessive thawing and freezing. The general care required is usually much less than for an ordinary flower-garden, but the pleasure to be derived from a well-constructed and well-planted rock-garden is very much more.

EDWARD J. CANNING.

RODGERSIA (named in honor of Commodore Rodgers, United States Navy). *Saxifragaceæ*. Hardy herbaceous perennials suitable for garden planting, with showy terminal flower-clusters.

Rootstocks horizontal, thick and black; lvs. alternate, large, peltate or digitately or pinnately compound, usually dark green; infl. tall and variously compound, paniculate; fls. very numerous, small; calyx-lobes 5; petals usually none; ovary 2-3-celled.—About 8 species, China and Japan. Botanically *Rodgersia* is close to certain species of *Astilbe*, having 10 stamens and no petals; it differs in having connate carpels, scorpioid infl. and 5-cut rather than thrice-ternate foliage.

Perhaps the best-known species is *R. podophylla*, as it was the first introduced into cultivation. It grows 3 to 4 feet high, and the leaves are finger-shaped, the five lobes being bold in outline, angled, and serrate. In the spring the foliage is light green; in summer it assumes a metallic bronzy hue. The plant is a vigorous grower, and under favorable circumstances has been known to make a clump 9 feet in diameter, the largest leaves being a yard across and borne on stalks 3 feet long. The flowers are borne in midsummer on stalks 4 to 5 feet high. The general style of inflorescence is that of the popular *astilbe*, to which it is closely allied. The flowers are very small, but make a feathery spray of fluffy white bloom. The panicle is a foot or more long and as wide at the base. Technically the flowers have no petals; what seem to be petals are the white calyx-segments. As a flowering plant it has been said by enthusiasts to be superior to *astilbe*, but the bloom is scantier, rather greenish at first, and perhaps does not last so long. It may not be so amenable to forcing. *Rodgersia* is a native of the subalpine regions of Japan and is presumably hardy in our northern states. It is offered by importers of Japanese plants. The plant is highly esteemed by English connoisseurs, but seems to be nearly unknown to American gardens. Although any deep rich garden soil will do, it is said to prefer a moist peaty soil. It should be placed in a sunny position, with plenty of room, where high winds cannot damage it. Easily propagated. (Wilhelm Miller.)

æsculifolia, Batalin. About 2½-6 ft. high: lvs. large, basal as much as 18 in. across, digitately compound, usually 7 lfts.; lfts. 4-10 in. long, narrowed to the

base, coarsely toothed: infl. 1½-2 ft. long, composed of flat clusters of white fls.; sepals rounded or blunt at apex; petioles, peduncles, and principal veins of lvs. covered with shaggy brown hairs. China.—The lvs. are like those of the horse-chestnut.

pinnata, Franch. Fig. 3420. Tall simple-branched, 3-4 ft. high, with a large horizontal rootstock: st. hollow: lvs. long-petioled, digitately pinnate; lfts. 5-9, 6-8 in. long, obovate or oblanceolate: fls. in a large much-

3420. *Rodgersia pinnata*.

branched panicle with rose-red rachis and branches; calyx puberulous, lobes ovate, red outside, white within. B.M. 7892. G.C. III. 32:131. G.M. 54:592. Gn. 73, p. 531; 76, p. 378. Var. *alba*, Hort., differs from the type in somewhat longer and broader panicles, the component parts of which are clustered more loosely: fls. white. China. G. 28:147. Var. *superba*, Hort., is much finer than the type, with the infl. more than 1½ ft. long: fls. delicate rose: fr. dark red. China.

podophylla, Gray. Herb with a thick scaly rootstock, 2-3 ft. high: basal lvs. few, long-petioled, peltately 5-foliolate, 6-18 in. diam.; lfts. sessile, 5-10 in. long, 3-6 in. broad, cuneately obovate or almost deltoid to above the middle, then trifid; margin coarsely serrate; cauline lvs. few, smaller, commonly 3-foliolate or 3-lobed: infl. a large panicle composed of scorpioid cymes; fls. small, yellowish white calyx-lobes spreading-ovate: caps. very small. China. B.M. 6691. G.C. II. 20:141. G. 13:239; 21:531; 35:67 and 431. Gn. 36, p. 171; 38, p. 125; 46, p. 34. G.M. 33:477. G.W. 5, p. 193. R.H. 1908, p. 15.

sambucifolia, Hemsl. About 2-3 ft. high: basal lvs. 9-15 in. long, long-petioled, bright green; lfts. in 3-5 widely separated pairs with an odd one at the top; the cauline lvs. solitary or 2 uneven pinnate, 9-11-foliolate; lfts. subsessile, subopposite and oblong-lanceolate: infl. small, terminal, densely cymose, paniculate; fls. white, small, and inconspicuous; sepals fleshy, ovate, sub-acute. China. G.C. III. 54:131.

tabularis, Kom. Herb, about 3 ft. high: lvs. very long-petioled, peltate, 1-3 ft. diam., shortly many-lobed, resembling teeth, the lobes broad-acuminate, usually sparingly setulose: infl. scapose, many-fld., resembling an *astilbe*; fls. small, white; calyx-lobes 5, broad obovate-oblong, rounded; petals 5, obovate-oblong. China. G.C. III. 44:210; 54:130. G. 35:829. Gn. W. 25:648.

F. TRACY HUBBARD.

RODRIGUEZIA (Emanuel Rodriguez, Spanish botanist and apothecary). Including *Burlingtônia*. *Orchidaceæ*. South American epiphytic orchids, a few of which are cultivated for graceful racemes of delicate flowers. Pseudobulbs small, compressed, 1-2-lvd. and bearing

sheathing lvs. at the base; racemes erect or pendulous; dorsal sepal and petals similar, free, erect; lateral sepals united, concave, but scarcely saccate; labellum spurred or saccate, with a long claw parallel to the column, and a spreading blade usually exceeding the sepal; column slender. Robert Brown's genus *Gomesa* (sometimes written *Gomeza*), founded on *G. recurva*, is by some referred to *Rodriguezia*. See *Gomesa*. The fls. are nearly always fragrant. The plants vary somewhat in habit. Some species form neat, compact tufts, while others, like *R. decora*, have long, straggling rhizomes difficult to keep within the limits of a block or a basket.

Rodriguezias should be grown in very shallow pots filled with tough peat, and well drained. Rest them in a temperature of 50°, giving little water. The growing temperature should be from 65° to 75°. Give plenty of moisture and shade from direct sunshine. The stronger-growing kinds will need thicker potting material in baskets; they do well wired on tree-fern stocks. During growth, syringing is necessary. (Wm. Mathews.)

A. Fls. large, white, spotted or rose.

B. Raceme erect.

décora, Reichb. f. (*Burlingtônia decora*, Lem.). Plant with a long, slender rhizome, with oval, 1-lvd. pseudobulbs; scape nearly erect, 9 in. high, bearing 5–10 blossoms in a loose raceme; sepals and petals ovate, acute, connivent, white or pale rose spotted with red; labellum

3421. *Rodriguezia secunda*. ($\times \frac{1}{4}$)

twice as long as the petals, white; middle lobe rounded, bifid, contracted into a broad claw which has several fringed lamellæ; column with falcate hairy ears. May, June. Brazil. B.M. 4834. F.S. 7:716. Var. *picta*, Hort. (*Burlingtônia decora* var. *picta*, Hook.). Pseudobulbs orbicular, compressed: fls. short, acute; sepals and petals spotted with deep purple-red. B.M. 5419.

BB. Raceme pendulous.

venusta, Reichb. f. (*R. fragrans*, Reichb. f. *Burlingtônia venusta*, Lindl. *B. fragrans*, Lindl.). Lvs. linear-oblong, forming compact masses: fls. in drooping racemes, large, white, or tinged with pink and having a yellow stain on the lip; dorsal sepal acute, the lateral pair entire; labellum transversely plicate near the middle. Flowers at various seasons. Brazil. I.H. 5:188. G.C. III. 4:757.—Very near *R. candida*.

cándida, Batem. (*Burlingtônia cándida*, Lindl.). Lvs. oblong, firm: racemes pendulous, 4–6-fld.; fls. white, with a light stain of yellow on the labellum, 2 in. long; dorsal sepal obovate, emarginate, the lower pair united into a concave, bifid blade, saccate at base; petals obovate, with the apex recurved; labellum with a broadly

cuneate, bifid middle lobe, longer than the sepals and petals; base and lateral lobes parallel to the column, throat with many lamellæ. April, May. Guiana. B.R. 1927. F.M. 1871:548.

pubescens, Reichb. f. (*Burlingtônia pubescens*, Lindl.). Lvs. tufted, dark green, keeled: racemes many, pendulous, from the tuft of lvs.; fls. pure white; labellum 2-lobed, hastate; lateral lobes erect, with lamellæ; column pubescent, in which it differs from other species.

AA. Fls. small, deep rose or spotted red.

secúnda, HBK. Fig. 3421. Pseudobulbs bearing several thick, linear-oblong lvs.: raceme erect, secund, 6 in. high; fls. deep rose; sepals erect, ovate, convex, the lower pair keeled and gibbous; petals like the dorsal sepal; labellum obovate-oblong, emarginate, scarcely longer than the sepals. Aug. Trinidad, Guiana. B.M. 3524. B.R. 930. L.B.C. 7:676 (as *R. lanceolata*).

críspsa, Lindl. Pseudobulbs elongate-ovate: lvs. oblong-lanceolate, spreading, undulate: raceme pendulous, rather dense; fls. green, with yellowish borders; sepals all free, undulate-crisp; petals similar; labellum lanceolate, sigmoid. Brazil. B.R. 26:54.

AAA. Fls. greenish.

planifolia, Lindl. Pseudobulbs clustered, compressed: lvs. lanceolate: raceme long, drooping; fls. greenish yellow, fragrant; sepals oblong, waved, acute, the lower pair united except at the end; petals like the dorsal sepal; labellum broadly oblong, acute, reflexed, shorter than the petals. Feb. Brazil. B.M. 1748 (as *Gomesa recurva*) 3504. L.B.C. 7:660 (as *Gomesa recurva*). See also p. 1354.

HEINRICH HASSELBRING.

RËTTLËRA, also spelled *Rottlera*: *Chirita*.

ROGIËRA: *Rondeletia*.

RÒHDEA (Mich. Rohde, physician and botanist of Bremen). Sometimes spelled *Rhodea*. *Liliacæ*. A monotypic genus of Japan and China, essentially a tender foliage plant with numerous radical lvs. 6–18 in. long: fls. borne among the lvs. in short thick dense spikes a few inches high; perianth globular-bell-shaped; anthers sessile; stigma peltate; style nearly wanting: fr. a globular, usually 1-seeded berry. Rohdeas are excellent plants for dwelling-house decoration, doing well in the cooler positions. They are perfectly hardy at Washington.

japónica, Roth. Root a long nearly cylindric rootstock with fleshy fibers: lvs. typically green, 9–12 in a rosette, erect, oblanceolate: berry about the size of a small olive, with a red pulp. B.M. 898 (as *Orontium japonicum*). Gn. 30, p. 541.—The following varieties, which differ in shape and color of the lvs., have been offered by Dutch bulb-growers: Vars. *aureo-striata*, *falcata*, *latimaculata*, *macrophylla*, *marginata minor*, *pygmæa*, *zebrina*.—This plant known as *Omoto* or *Mannensei* is a favorite among the Japanese, and fine specimens often bring as much as \$500, even when only a few inches high. The seven standard varieties of Japan are *Hinomoto*, *Nagashima*, *Kyuanji*, *Shikami*, *Daimyôsei*, *Jindai*, and *Akitsushima*. Retired persons of means often spend their declining years in the culture of this interesting plant, of which hundreds of named varieties are known to Japanese fanciers. A number of very beautiful books have been written on this plant, and it has an extensive literature. This plant is well known in China and was adopted by the Manchus as their national flower. L. H. B.†

ROLLÍNIA (named in honor of the French historian, Charles Rollin). *Annonacæ*. BRIBÁ. ARATICÚ. CACHIMAN. Tropical American shrubs and trees.

Fruits fleshy, compound, subglobose, resembling those of *Annona*, but with fls. very distinct in form from those of *Annona*: corolla gamopetalous with the lobes corresponding to the outer petals of *Annona* pro-

duced into 3 rounded wings or obtuse spurs, in some species horizontally projecting, in others curved upward and inward, in others outward and downward; lobes corresponding to the 3 inner petals, alternating with the winged or spurred lobes, reduced to minute scales, almost closing the opening above the essential

3422. Types of Rollinia flowers. *a*, *R. Sieberi*; *b*, *R. deliciosa*; *c*, *R. laurifolia*; *d*, *R. rugulosa*; *e*, *R. lanceolata*; *f*, *R. emarginata*.

parts. The type species is *R. dolabripetala*.—The genus, including about 50 species, ranges from Mex. and the W. Indies southward to Argentina and Peru. It is well represented in Brazil and Paraguay. In some of the species the frs. are highly prized for the table and rival the cherimoya, for which they have sometimes been mistaken. Several have been intro. into cult. through the Miami (Fla.) Station by the Office of Foreign Seed and Plant Introduction, U. S. Dept. of Agric. Much confusion has resulted from the fact that in many original descriptions of species of Rollinia, the frs. were not included, and that edible frs. in the markets unaccompanied by lvs. or fls. have in many cases been botanically misidentified. It is impossible here to give a key to all the species. The principal ones may be grouped according to the form of the fl. into sections or subdivisions, as indicated in the accompanying illustration (Fig. 3422).

A. Corolla-wings oblong, laterally compressed, widely spreading and more or less ascending. (Fig. 3422, a.)

1. *dolabripétala*, St. Hil. (*Annona dolabripétala*, Raddi. *Rollinia longifolia*, St. Hil.). HATCHET-LOBED ROLLINIA. A small tree, 16½–23 ft. high: young branches, together with the lower surface of the young lvs., their petioles, and the fls. ferrugineous-tomentose: vegetative lvs. oblong-lanceolate or oblong, 4–6 in. long and about 1½ in. broad, those of the flowering branches much smaller, acutish or acute, or sometimes subacuminate at the apex, obtuse at the base, glabrous above, rufous-pubescent beneath, with the midrib prominent beneath, ferrugineous, with 20–28 lateral nerves; petiole about ½ in. long, grooved above, persistently ferrugineous-tomentose; peduncles solitary or rarely in pairs, ferrugineous-tomentose, bracteolate at the base, ½–1½ in. long; calyx-divisions cordate-ovate or suborbicular; corolla-wings rather fleshy, 1 in. long, ferrugineous-tomentose, laterally compressed in the form of a hatchet or broad knife with its blade in a vertical plane, at first ascending, at length broadly spreading; fr. (immature) globose, squamose, pubescent, with the areoles slightly convex; seeds compressed, somewhat cuneate, testa reddish yellow, thin, showing

the wrinkles of the inclosed ruminant endosperm. This species, the type of the genus Rollinia, was first collected on Mt. Corcovado, near Rio de Janeiro, Brazil, where its fls. appeared in Feb. and its fr. in May.

2. *mucosa*, Baill. (*Annona mucosa*, Jacq.). CACHIMAN MORVEUX. A small tree first described by Jacquin from specimens growing spontaneously in the forests of Martinique, and said by him to be rarely cult. In habit it bears a close resemblance to the common custard-apple, *Annona reticulata*. Lvs. oblong, pointed at the apex and base: corolla gamopetalous in the form of a roundish body from which 3 oblong lobes spread outward in such a way that it not inaptly represents a tricorn hat: areoles of fr. gibbous (convex) not papillose nor aculeate; fleshy pulp very viscous and not very well flavored.—*R. Sieberi* has been referred to this species, but Père Duss, in his Flora of the French Antilles has kept the two species distinct.

3. *Sieberi*, A. DC. CACHIMAN MONTAGNE. A small tree first described and figured from the island of Trinidad and erroneously referred by its collector to the common custard-apple, *Annona reticulata*, to which its fr. and lvs. bear a certain resemblance: lvs. oval-oblong, acute at apex and base, usually 5–6 in. long and 2–3 in. broad, thin, above puberulous with the nerves pilose, beneath paler and more pilose, narrowed at the base into pilose petioles ¼ in. long, some of them at the base of the branches broadly ovate and obtuse, about 1 in. long: peduncles lf.-opposed, 1-fl., 1–1½ in. long, bearing 2 small ovate-acute bracteoles, one near the base, the other about the middle: corolla-wings laterally compressed, linear-oblong, rounded at the apex, diverging, straight or curving slightly upward; fr., according to Père Duss, usually larger than that of *Annona squamosa*, the surface divided into pronounced raised squamose

3423. *Rollinia deliciosa*. (×½)

areoles rounded at the tips; pulp fleshy, nearly white, melting in the mouth, slightly viscous, with a sugary agreeable flavor. Type collected by Sieber (No. 96), in the De Candolle Herbarium.

AA. *Corolla-wings laterally compressed, widely spreading and more or less decurved.* (Fig. 3422, b.)

4. *deliciosa*, Safford. BIRIBA. Fig. 3423. A tree yielding a delicious, large, juicy fr., resembling the cherimoya: vegetative lvs. obovate-oblong or elliptical, rounded at the base and normally acuminate at the apex, blades 8–11 in. long and 3–4 in. broad, membranaceous, when young sparsely canescent-hirtellous above, densely so beneath, especially along the midrib and nerves, at length glabrous above and beneath except along the midrib and primary nerves (18–22 on each side), these reddish brown and slender but prominent

3424. *Rollinia Jimenezii*. ($\times \frac{1}{2}$)

beneath; petiole about $\frac{3}{8}$ in. long; lvs. on flowering branches smaller, the lowermost ones relatively shorter and broader, sometimes broadly ovate or orbicular, $1\frac{1}{2}$ – $2\frac{1}{2}$ in. long and $1\frac{1}{2}$ –2 in. broad; peduncles lf.-opposed, often in pairs, sometimes solitary, rarely in 3's, 1– $1\frac{1}{2}$ in. long, bearing a small ovate sessile bracteole near the middle, strigillose with reddish hairs, like the petioles and nerves of the lowermost lvs. (prophylla) beneath; calyx and corolla canescent-puberulous; corolla-wings compressed laterally, widely diverging and decurved, rounded at the extremity; stamens numerous, closely crowded, the expanded connectives forming a pavement above the pollen-sacs; carpels numerous, ovaries hairy, styles expanded, glandular-puberulous; fr. a solid depressed subglobose syncarpium, 3–5 in. diam. with the areoles distinctly outlined and terminating in an obtuse beak; peduncle straight and woody, about 2 in. long; pulp fleshy, white or cream-colored, juicy, fine-flavored; seeds compressed, $\frac{3}{8}$ – $\frac{1}{2}$ in. long and $\frac{1}{8}$ – $\frac{3}{8}$ in. broad, rounded at the apex, gradually narrowing to the base, hilum not prominent; testa thin, brown, wrinkled by the inclosed ruminate endosperm.—The type of this species, in the U. S. National Herbarium, is from a fr.-bearing tree cult. in

the experiment station, Miami, Fla., grown from seeds sent by C. F. Baker from Para, Brazil (No. 22512) in 1908. Baker describes it as the finest annonaceous fruit of Trop. Amer. It was incorrectly referred to *R. orthopetala*, but it is readily distinguished from that species by the decurved wings of its fls.

5. *Pittieri*, Safford. A tree resembling *R. deliciosa*, but with lvs. more abruptly acuminate and glaucous beneath, the vegetative ones 6–8 in. long and $3\frac{3}{4}$ in. broad, midrib and primary nerves (16–20 on each side) reddish brown beneath; lvs. on flowering branches smaller (with 10–12 primary nerves); peduncles often in clusters of 3 or 4, graduated in length, the longest $1\frac{1}{2}$ in. long, rufous, minutely puberulent, never hairy like those of *R. deliciosa*, bracteolate near the middle; corolla-wings $\frac{3}{8}$ – $\frac{1}{2}$ in. long, falcate, horizontally extended and decurved, rounded at extremity, and narrowed at the base, very finely puberulent, appearing under the lens as though composed of olive-gray felt; fr. not observed.—A beautiful species with elliptical or obovate lvs. remarkable for the pale color of the lower surface and the sharply outlined lateral nerves. These correspond with the description of *R. rufinerva*, Triana and Planch., but the corolla-wings are decurved, not "divergent ascending," as in that species. The type, in the U. S. National Herbarium, was collected near Puerto Obaldia, Panama, by Henry Pittier (No. 4358), in whose honor the species is named.

6. *Jimenezii*, Safford. ANONILLA. Fig. 3424. A small tree of Costa Rica resembling *R. mucosa* but with fls. in clusters of 2 or 3, having the corolla-wings horizontally spreading and slightly decurved, and with fr. resembling that of the common sugar-apple (*Annona squamosa*), with the component carpels rounded at the tips when fresh, but more or less beaked when dry; lvs. ovate to oblong-elliptical, acuminate, those of the vegetative branches 7–8 in. long and $2\frac{3}{4}$ –3 in. broad, obtuse at the base, with 18–22 primary nerves on each side of midrib, those of the flowering branches smaller with 12–16 pairs of primary nerves and usually rounded at the base; point of acumen either acute or more usually obtuse or retuse; young branches, petioles, and lower surface of young lvs. covered thickly with ferrugineous hairs, lvs. at length glabrous or nearly so except along the midrib and nerves beneath; peduncles lf.-opposed, in clusters of 2 or 3, graduated in length, the longest about $\frac{1}{2}$ in. long, ferrugineous-tomentose like the ovate-acuminate calyx-lobes; corolla-wings oblong, rounded at the tip, scarcely at all narrowed at the base, widely spreading and usually decurved, never curving upward and inward, rufous-puberulent; fr. subglobose, about $2\frac{3}{4}$ in. diam., closely resembling that of *Annona squamosa*, the component carpels loosely adhering, very gibbous, rounded or often retuse at the tip when fresh; pulp white, edible, but not so agreeably flavored as that of *Annona squamosa*.—This species is based upon specimens in the U. S. National Herbarium, received from Oton Jimenez, of San José, Costa Rica, the fls. collected by him at Nuestro Amo, March, 1912 (No. 427), and the fr. from the same tree, Oct., 1912. The accompanying figure is drawn from type material, the fr. from a field photograph sent by Mr. Jimenez, in whose honor the species is named.

AAA. *Corolla-wings linear-oblong or spatulate, ascending or erect and incurved.* (Fig. 3422, c.)

7. *orthopetala*, A. DC. A shrub or small tree with the habit of *R. Sieberi*, but with the lvs. somewhat longer petioled; lvs. oval-oblong, acute at apex and base, pilose; peduncles in pairs; calyx-lobes smaller than in *R. Sieberi*; corolla-wings erect and incurved; fr. not described.—This species was described by De Candolle from a specimen in the De Candolle Herbarium collected by Parker near Demarara, British Guiana. The name has been incorrectly applied to several rollinias with edible fr. Of these the principal

species, from an economic point of view, is *R. deliciosa* described above, which is readily distinguished from *R. orthopetala* by its widely spreading decurved corolla-wings.

8. *laurifolia*, Schlecht. ARATICÚ MIRIM. A shrub or small tree with the new branchlets, petioles, peduncles, midrib, and nerves finely appressed-subfurfuraceous puberulent, the fls. and lower surface of the lf. clothed with finer and denser clay-colored puberulence: lvs. oblong-elliptical or oblong-lanceolate, acuminate, obtusish at the base, $3\frac{1}{2}$ –5 in. long, $1\frac{1}{2}$ – $1\frac{3}{4}$ in. broad; midrib prominent beneath, lateral nerves 10–15 pairs; upper surface apparently glabrous, but as seen under a lens covered with minute appressed white hairs: peduncles solitary or in 2's or 3's, graduated in length, the longest 3 times as long as the petioles (1 in. long), bracteolate at the base, gradually thickening toward the apex: corolla-wings ascending-erect, broadened at the apex, rounded or quite obtuse, $\frac{3}{4}$ in. long and $\frac{1}{4}$ in. broad near the apex, clothed with minute brownish-argillaceous tomentum: fr. subglobose, about the size of a horse-chestnut, composed of many carpels distinctly outlined and containing an edible, white, mucilaginous pulp with a pleasant sweet taste.—This species is based upon 2 flowering specimens collected in Brazil by Sellow (Nos. 809 and 1190).

9. *incurva*, Moore. A diffuse shrub with long branches: lvs. short-petioled, lanceolate or lanceolate-oblong, obtuse, rounded at the base, coriaceous, above glabrous, often glossy, beneath paler, minutely puberulous, blades 4–5 in. long, $1\frac{1}{2}$ –2 in. broad, often more or less oblique at the base; midrib impressed above, rather prominent beneath, lateral nerves about 12 pairs inserted at a wide angle, undulate near the margin and curving upward: peduncles usually in pairs, sometimes solitary, longer than the petioles ($1\frac{1}{2}$ in. long), bracteate at the base, and bearing a small bracteole near the middle, puberulous: fls. yellowish green; calyx-lobes short and rounded, ferrugineous-pubescent; corolla-wings ferrugineous-tomentose, spatulate-oblong, ascending and incurved, $\frac{3}{4}$ in. long; stamens numerous, crowded; carpels albo-sericeous: fr. not observed.—This species described by Spencer Moore, was collected in Santa Cruz, Brazil, by the Matto Grosso expedition. Specimens from the type collection are in the Herbarium of Columbia University, at the Botanical Garden, New York City.

AAAA. Corolla-wings compressed, obovate, and ascending.

(Fig. 3422, d.)

10. *rugulosa*, Schlecht. A shrub or small tree: lvs. lanceolate, or broadly lanceolate, obtusely and shortly acuminate, acute at the base, on both sides subglabrous, beneath glossy; young branchlets, petioles, and midrib appressed-puberulous: peduncles usually recurved or pendulous and thickened at the apex, warty and puberulous like the calyx, $\frac{1}{6}$ – $\frac{2}{3}$ in. long: corolla-wings obovate, ascending, rounded or obtuse at the apex, narrowed at the base, tomentose-canescens, $\frac{1}{4}$ in. long and $\frac{1}{4}$ in. broad: fr. globose, 1– $1\frac{1}{2}$ in. diam., with the component carpels forming 20–30 slightly raised rounded areoles; seeds small, pale brown, conoid, somewhat flattened.—Type collected in S. Brazil by Sellow. Closely related to *R. rugulosa* and with very similar fr. but with longer and narrower lvs. (suggesting those of *R. salicifolia*), is *R. Warmingii*, R. E. Fries, the type of which was collected on Mt. Tijuca, near Rio de Janeiro, by Glaziov (No. 6079).

AAAAA. Corolla-lobes or -wings short, straight and spur-like, horizontally directed. (Fig. 3422, e.)

11. *lanceolata*, R. E. Fries. A small tree with small lanceolate lvs.: lvs. acute at the apex and base, above glabrous except along the midrib; beneath densely ferrugineous-villous along the midrib: young branches, petioles, and solitary or rarely geminate peduncles fer-

rugineous-tomentose: fls. ferrugineous-hirsute; outer corolla-lobes spur-like, short, rounded, and widely spreading: fr. not observed.—This species is based by Robert E. Fries on a specimen in the Copenhagen Herbarium collected by Glaziov in Brazil (No. 13509).

AAAAAA. Corolla-lobes or -wings broadly ovate or suborbicular, and compressed. (Fig. 3422, f.)

12. *emarginata*, Schlecht. A glabrescent shrub, $6\frac{3}{4}$ –10 ft., growing in marshy places, with slender branches: lvs. oval or elliptical, obtuse at both ends or acutish at the base, emarginate or retuse at the apex, on both sides subglabrous and opaque: peduncles usually solitary, slender, about 1 in. long, minutely bracteolate at the base: corolla and calyx silky-hirtellous; corolla-wings obovate-orbicular, widely spreading, laterally compressed: fr. solid, about 1– $1\frac{1}{2}$ in. diam., ovate-globose, with the component carpels scarcely at all raised or distinctly outlined.—This species, very common in S. Brazil and Paraguay, is based upon specimens collected in the province of Rio Grande do Sul by Sellow.

13. *glaucescens*, Sond. A glabrescent shrub closely allied to *R. emarginata*, but with the lvs. not emarginate and sometimes acute at the apex: lf.-blades ovate or lanceolate, obtuse or rarely acute at the apex, acute at the base, 2–3 in. long and 1 in. broad, glaucescent beneath; petioles $\frac{1}{6}$ – $\frac{2}{3}$ in. long: peduncles in pairs, one shorter than the other, the longer one bearing a small bracteole below the middle; fls. canescent-puberulous; corolla-wings broadly obovate or suborbicular, widely spreading: fr. broadly ovoid or subglobose, small (about 1 in. diam.), solid and smooth, with the component carpels scarcely outlined and not at all gibbous.—Specimens in the U. S. National Herbarium collected by Dorsett, Shamel, and Popenoe, in S. Brazil.—This species was based by Sonder on a plant collected by Regnell on his second expedition, in the province of Minas Geraes, Brazil.

14. *sylvatica*, St. Hil. ARATICÚ DO MATO. A medium-sized tree: lvs. elliptical or oblong, shortly acuminate, acute, or obtuse at the apex, acutish at the base, above puberulous when young, at length glabrous, beneath softly tomentose; petiole, midrib, and veins clothed with ferrugineous hairs, the remainder of the lower surface with white hairs: peduncles solitary or in pairs, clothed with ferrugineous tomentum; corolla-wings suborbicular: fr. globose, solitary, the size of a small apple, pubescent, with the component carpels forming prominent pentagonal areoles; pulp edible, somewhat like that of the cherimoya.

W. E. SAFFORD.

ROLLINIOPSIS (Greek derivative, signifying *Rollinia*-like, from the form of the fl.). *Annonaceae*. FRUCTA DE MACACO. MONKEY-FRUIT. Shrubs or small trees of Brazil having fragrant 3-winged fls. like those of *Rollinia*, but with aromatic frs. in the form of a cluster of small distinct drupes, instead of a fleshy sweet syncarpium, as in *Rollinia*.—Only 4 species have thus far been described, all from Trop. Brazil. The type of the genus (*R. discreta*, Safford), Fig. 3425, has been successfully intro. into cult. in the S. U. S. by the Office of Foreign Seed and Plant Introduction, U. S. Dept. of Agric. (S. P. I. No. 15508). This species, discovered by Dorsett, Shamel, and Popenoe in the vicinity of Januaria, state of Minas Geraes, has orange-colored pear-shaped drupes, locally known as Fruta de Macaco (monkey-fruit). The thin aromatic mesocarp surrounding the solitary seed tastes very much like the fr. of certain species of *Xylopia*, called malaguetas in the vicinity of Panama, and also suggests the flavor of the Mexican *xochinacaztli*, or earflower (*Cymbopetalum penduliflorum*) the spicy petals of which, together with vanilla, were used by the Aztecs for flavoring their chocolate in pre-Columbian times (see *Cymbopetalum*). The other known species are *R. simiadrum*, Safford, recently discovered by Rose and Russell, of the Carnegie

Expedition, in the state of Bahia; *R. parviflora* (Rollinia parviflora, St. Hil.), of Rio de Janeiro; and *R. leptopétala* (Rollinia leptopétala, R. E. Fries), of Piahy, Brazil.—See Journ. Wash. Acad. Sci., vol. 6, p. 1916.

W. E. SAFFORD.

ROMANOVIA (derivation unknown). Also spelled *Romanovia*. *Palmaceæ*. A genus founded in G.C. III. 33:245 without generic description. *R. Nicolai*, Hort. A calamus-like palm with mealy down on the sts., long slender petioles without prickles; lvs. pinnate with

3425. *Rolliniopsis discreta*. a, Flower with a portion removed to show the mass of stamens surrounding the cluster of carpels beneath the minute inner petal, or corolla-lobe ($\times 1\frac{1}{2}$); b, a pair of stamens, showing a pair of parallel pollen-sacs beneath the expanded tip of the connective ($\times 5$); c, mature carpels which have fallen off the receptacle ($\times \frac{1}{2}$); d, seed ($\times \frac{1}{2}$).

remote segms., tapering to a wedge-shaped base and with the retuse apex divided irregularly into long acutely pointed lobes, somewhat as in caryota. Habitat not given. G.C. III. 33:suppl. April 25, p. iii.

ROMANZOFFIA (named in honor of Count Nicholas Romanzoff). *Hydrophyllaceæ*. Low and delicate perennial herbs with the aspect of saxifrage, suitable for outdoor planting.

Leaves mainly radical, alternate, round-cordate or reniform, crenately 7–11-lobed, long-petioled; infl. scapose, racemously or paniculately several-flid.; the pedicels filiform; fls. pale pink or purple, varying white; calyx-lobes oblong-linear or lanceolate; caps. retuse, 2-celled or nearly so.—Ten(?) species, Alaska southward to the coast range of Calif.

unalaschkensis, Cham. Rootstock not tuberous: scape erect, 3–5 in. high; the erect or ascending pedicels shorter than the fls.; calyx-lobes herbaceous; corolla very short-funnelform. Unalaska, and one isolated station in N. Calif.

sitchensis, Bong. Rootstocks slender and tuberous: plant sparsely pubescent or glabrate; scape filiform, weak, 6 in. high; the spreading pedicels longer than the fls.; calyx-lobes very glabrous; corolla funnelform. Alaska south to Monterey County, Calif. G. 36:649.

F. TRACY HUBBARD.

ROMNEYA (named for T. Romney Robinson, who discovered it about 1845). *Papaveraceæ*. Tall showy herbs or subshrubs used for garden planting.

Stems branching; lvs. petioled, pinnatifid, 2 or 3 pairs of segms.: fls. solitary at the ends of the corymbose branches, large, white and showy, 6 in. across; sepals 3, with a broad membranaceous dorsal wing; petals 6, all alike; stamens very numerous; stigmas numerous, connate at base into a little ring; caps. 7–11-celled, dehiscent to the middle, the valves separating by their margins from the firm persistent placentæ.—Two species, Calif. and Mex. Monographed by Fedde in Engler's Pflanzenreich, hft. 40 (IV. 104), 1909.

Romneya grows wild in California from San Diego to Santa Barbara County and also in Mexico, and in the wild state it blooms chiefly in June and July, but in cultivation the period of bloom is increased from May to August. In the region of Los Angeles, it is said to thrive best on dry rocky soil and needs only the water it obtains from the winter rains. Romneya can be transplanted safely if cut to the ground before it is lifted and can be raised from seed if the seed is fresh. Raising from seed under artificial conditions is not very satisfactory, however, as it takes a few years between the germination of the seed and blooming of the seedlings.

Romneya is difficult to transplant, due to the scarcity of fibrous roots; in middle California suckers which are produced in great abundance are transplanted without any loss, provided a good firm ball of earth is kept around the stout thick roots in transit, and if the stems are cut well back, almost to the base. At San Francisco it grows luxuriantly in a heavy adobe soil, producing immense flowers. The name Matilija poppy (pronounced Ma-ti-li-ha) is the favorite in California. It comes from the Matilija Cañon, Ventura County, where the plant grows in particular abundance. Miss Parsons writes: "Many people have the mistaken idea that it grows only in that region. It is not common by any means; but it is found in scattered localities from Santa Barbara southward into Mexico. It is very abundant near Riverside, and also upon the southern boundary and below in Lower California, where the plants cover large areas. It not only grows in fertile valleys, but seeks the seclusion of remote cañons, and nothing more magnificent could be imagined than a steep cañon-side covered with the great bushy plants, thickly covered with enormous white flowers." Blossoms remain open for many days. (J. Burt Davy.)

3426. Top sprig of *Romneya Coulteri*. ($\times \frac{1}{2}$)

XCVIII. Romneya Coulteri, the Matilija poppy, one of the most showy of California flowers

Cöhlteri, Harv. *MATILJA* POPPY. Fig. 3426. Sts. flexuous, more branched above; lvs. rather papery than subcoriaceous, somewhat glaucous; the lower trijugate, the lobes lanceolate, the terminal one ovate; calyx rather glabrous, sepals purplish at the apex; petals white, membranaceous, thickened toward the base; caps. spreading, setose. Calif. and Mex. G.C. III. 27:131. G. 8:603; 35:3. Gn. 13:494; 26:400; 29, pp. 207, 211; 46, p. 405; 55, p. 208; 56, p. 239; 57, p. 263; 62, p. 63; 68, p. 89; 76, p. 611. G.M. 43:36. Gn.W. 20:19. G.F. 10:353. F.M. 1877:252. A.F. 5:397. A.G. 19:314 (suppl. April 16, 1898). C.L.A. 1:76.—Though not considered hardy in the eastern states, it has been successfully grown outdoors in northern states.

trichocalyx, Eastw. Sts. stout, erect, more simple above; lvs. subcoriaceous, 3-lobed or 3-dentate; calyx subglobose; caps. appressed setose. Calif. G.C. III. 42:414. G. 35:571; 37:65. Gn. 77:291. G.M. 54:186.

F. TRACY HUBBARD.

ROMULÈA (a name commemorative of Romulus, one of the mythical founders of Rome). *Iridacæ*. Crocus-like bulbs, suitable for outdoor planting.

Leaves narrow, usually overtopping the fls.: sts. produced, simple or branched; spathe of 2 lanceolate valves; fls. lilac, purple, yellow or pale, always solitary; perianth funnel-shaped, about 1 in. across; ovary 3-celled; caps. globose or ellipsoid.—About 90 species, *Medit. region*, *Trop.* and *S. Afr.* They are closely allied to *Crocus*, but differ in being less hardy and in having a long peduncle and short fl.-tube. Very little known in cult. in Amer.

AA. Fls. rosy or crimson.

rosea, Eckl. (*Trichonema rosea*, Ker). Corm globose, $\frac{1}{8}$ – $\frac{1}{2}$ in. thick; lvs. $\frac{1}{2}$ –1 ft. long, setaceous; peduncle 1–6 in. long, 1–3-fld.; outer spathe $\frac{3}{4}$ in. long; perianth with a short funnel-shaped tube with a yellow throat and a red-lilac limb, about 1 in. long, the outer segms. with 3 faint purple stripes outside. *S. Afr.* B.M. 1225 (as *T. roseum*). F.S. 8:799 (as *R. Celsii*). G.C. III. 58:37. Gn. 79, p. 232. Var. *speciosa*, Baker (*T. speciosum*, Ker), has a larger perianth and outer segms. with 3–5 dark purple stripes of which the outer are feathered. B.M. 1476.

AA. Fls. yellow or white.

Clusiæna, Baker (*Trichonema Clusiæna*, Lange). Fls. bright yellow, tipped with lilac. Spain. A white variety has been intro. abroad by Barr.

Macdwanii, Baker. Sts. very stout, 1-fld.: fls. bright golden yellow in the lower part, paler upward and sometimes tinged with red; perianth-segms. oblong. *S. Afr.* G.C. III. 58:35.

R. Bulbocodium, Sebast. & Mauri(?), has pale lilac fls. with a yellow center, tinted golden brown, striped with blue outside. Italy and Spain. G. 34:307. B.M. 265 (as *Ixia Bulbocodium*). There is another *R. Bulbocodium*, that of Kunze, which is the same as *R. Clusiæna*.—*R. Leichtlinii*, Hort., has cream-white crocus fls. with a golden center.

F. TRACY HUBBARD.

RONDELETIA (named in memory of William Rondelet, 1507–66, a French physician and naturalist). Syn. *Rogiera*. *Rubiaceæ*. Evergreen shrubs and trees, a few of which are grown in the warmhouse or outdoors in the extreme southern United States.

Leaves opposite, rarely ternately whorled, sessile or petiolate, coriaceous or membranaceous; infl. corymbose or paniculate, axillary or rarely terminal cymes; fls. red, yellow or white; calyx-lobes equal; corolla-tube usually slender, swollen or not, throat glabrous or bearded; limb 5-lobed (in some species 4-lobed); ovary 2-celled; caps. loculicidal.—About 85 species, *Trop. Amer.* The whole family is noted as furnishing numerous desirable stove plants, and *Rondeletia* is a highly esteemed genus. The following species are shrubs growing 4 ft. or more high. The fls. are generally fragrant, and the clusters 4 in. or more across.

In the favorite species (*R. odorata*) the fls. number 10–30 in a cluster, each fl. being fully an inch across; in the other species the fls. may number 150–200 to a cluster, each fl. being less than $\frac{1}{2}$ in. across. *R. cordata* is often said to have a 4-lobed fl., a mistake that dates back more than half a century to a typographical error.

Rondeletias are of slow growth, and not many cultivators of plants care to give time and space to raise them; nevertheless some of the species, notably *R. odorata* var. *major*, deserve to be more widely grown. Cuttings from the half-ripened wood may be rooted at any time of the year. Spring, however, is considered the best time, as one has the season's growth ahead, and good plants may be had in the fall. Insert the cuttings in a 3-inch pot, in a mixture of finely sifted peat and sand and place them in a tight propagating-bed, in a temperature of 70°. Water them thoroughly and shade them from the sun. In a few weeks the cuttings will be rooted, when they may be potted in small pots, in the siftings of the root of the *osmunda* fern, with enough sand to keep it open. If a good fibrous peat can be procured, it answers the same purpose. A night temperature of 60° is best for these plants. Large plants, however, will winter safely at 50° to 55°. The advantage

of keeping small plants warmer is that they may be grown more quickly. As soon as the young plants have a good hold on their first pot, cut them back to two joints above the soil. Place them close to the glass and syringe two or three times a day. When the sun gets strong, shade them lightly in the middle of the day.

As soon as they are well rooted in their first pot, shift them into a size 2 inches larger, which will carry them

3427. *Rondeletia cordata*.
($\times 1/4$)

through until the following spring. They would flower in this pot if allowed to do so, but it is advisable to keep them growing right along the first year. They may be cut back as soon as the shoots are long enough to leave two sets of leaves, after the heart has been taken out of them. As the plants grow larger, a third part of good fibrous loam may be added to the peat, and at all times they must be potted very firmly. After the plants have reached the size of an 8-inch pot, they may go two seasons without repotting, if they are fed with liquid manure as advised for *ixoras*. After color shows in the flowers, it is best to withhold manure until they have finished flowering, as the flowers will last much longer. After the flowers decay, if they are removed without cutting away much of the stem, they are liable to flower a second time the same year. It is preferable, however, to cut them well back, and if they require potting, do so, after they have broken into growth. When the young breaks have made four pairs of leaves, take out the heart of them. This treatment will double the number of shoots, and give a far better appearance when they come in flower. Mealy-bug will sometimes be found on *rondeletias*. They may be easily gotten rid of if the plants are removed to a house that is being fumigated with hydrocyanic gas. (George F. Stewart.)

A. *Fls. red.*

odorata, Jacq. (*R. speciosa*, Lodd.). Lvs. ovate, nearly sessile: clusters 10-30-fl.: fls. crimson to brick-red, with a conspicuous yellow throat; lobes elliptical to roundish. Cuba, Mex. B. 2:53. B.M. 3953. B.R. 1905. F.C. 1:36. L.B.C. 19:1893. P.M. 2:242; 16:354. R.H. 1891:522 (throat not conspicuously yellow). G.W. 6, p. 125. Var. *major*, Hort., is a form with larger fls.

AA. *Fls. pink to white.*B. *Base of lvs. more or less cordate.*

cordata, Benth. (*Rogiera cordata*, Planch. *R. thyrsoflora*, Hort., not Roth). Fig. 3427. Lvs. ovate, acuminate, cordate: generally said to have pink or flesh-colored fls. with a yellow throat (as in F.S. 8:754), but in R.H. 1878:230 they are shown as pure white. B.M. 8540. J.F. 2:122. Guatemala. Possibly also native in Mex.

latifolia, Hort. (*Rogiera latifolia*, Decne.). Lvs. large, heart-shaped, acuminate, short-petioled: fls. in corymbose cymes, the tubes pink, the limb white; calyx-lobes oval, obtuse. Guatemala. R.H. 1853:121.

BB. *Base of lvs. not cordate.*C. *Corolla-lobes ovate: stipules broadly ovate.*

amena, Hemsl. (*Rogiera amena*, Planch.). Lvs. elliptic, broader than in *R. gratissima*, and shorter, acuminate, 2-5 in. long: fls. rose-pink, with a conspicuous yellow throat. Guatemala. F.S. 5:442.—Intro. in Calif. See also *R. versicolor*, in suppl. list below

CC. *Corolla-lobes obovate: stipules subulate.*

gratissima, Hemsl. (*Rogiera gratissima*, Lind.). Lvs. oblong-elliptic, 1-2 in. long, short-petioled, mostly rounded at the base: fls. with a bright rosy tube, the lobes fading from pale rose to whitish; throat not conspicuously yellow. Trop. Amer. I.H. 28:424. F.S. 15:1570 (corolla-lobes often obovate; stipules narrowly ovate). Gt. 490 (as *Rogiera elegantissima*). J.H. III. 52:365.

AAA. *Fls. blue. (Hindsia.)*

longiflora, Cham. (*Hindsia longiflora*, Benth.). Lvs. opposite, entire, lanceolate, more or less oval or sometimes almost linear, petiole very short, attenuate at the base: infl. terminal corymb; fls. blue; calyx-tube short, lobes linear; corolla-tube very long; segms. of lip oval, spreading and acuminate. R.H. 1858, p. 329. H.U. 4, p. 243.—This is now placed in the genus *Hindsia*, which differs from *Rondeletia* in general appearance and in the form of the corolla which is rather funnel-shaped than salver-shaped, without any callous contraction or beard at the mouth of the tube and by the caps. which is differently dehiscent. A second species of *Hindsia* is *H. violacea*, Benth., from Brazil. B.R. 30:40.

The following species have been occasionally cult.: *R. americana*, Linn. White-fl. W. Indies and S. Amer.—*R. anomala*, Hort., is an imperfectly known species said to have the lvs. in 3's, and coral-red or deep scarlet fls. with a presumably yellow throat. Habitat (?).—*R. Bäckhousii*, Hook., a pink-fl. species from Trop. Amer., is easily distinguished from those mentioned above by the much longer calyx-lobes, which are pink. B.M. 6290.—*R. Pürdiei*, Hook., a beautiful pale yellow-fl. species from Colombia, has a great pyramidal cluster 5 in. across and 4 in. deep, with an astonishing number of fls., perhaps 150-200 in B.M. 5669.—*R. versicolor*, Hook. (*Rogiera versicolor*, Lindl. & Paxt.), is referred to *R. amena* by Index Kewensis but seems distinct. The fls. are said to be "remarkable for their play of colors: the tube is yellow; the limb in bud deep rose-color, changing when they expand to pale rose and then to white, with a yellow disk, and having a 2-lobed green spot in the center from the color of the stigmas, which protrude a little beyond the mouth." B.M. 4579. J.F. 2:112.

F. TRACY HUBBARD,†

ROOT-GALLS. Abnormal enlargements often appear on the roots of plants. These enlargements are much more frequent than is generally supposed, but from their position under ground are rarely observed. From an economic standpoint they have not received the attention that they merit.

Although the term root-gall is usually applied to the abnormal enlargement of roots due to insects and other animal organisms, it has a much wider application as used by most plant-growers. The presence of nodules or local enlargements on the roots of plants has been discussed by different authors under the names root-galls, root-knots, root-swellings, and the like. In cases in which the cause of the nodules of hypertrophied tissue is known, special names have been assigned to the enlargements. Thus the gall formed by the eel-worm (*Heterodera radiculicola*) is known as the nematode root-gall (Fig. 3428); the enlargement on the roots of cabbage and related plants by the myxomycete (*Plasmodiophora Brassicæ*) is called club-root; the swellings on the roots of the peach, apricot, and many other plants, which are of characteristic appearance and usually appear at the crown of the plant, are known as crown-gall. Root-tubercles are small gall-like bodies found on the roots of many leguminous plants. They are symbiotic in nature, the organism causing them being helpful to the plant. See *Legumes*.

Abnormal root enlargements are due to the following causes: (1) animal parasites, as in the nematode root-gall (Fig. 3428), the galls formed on the roots of

3428. Root-galls due to nematodes.—
Tomato roots.

the grape by the phylloxera, woolly aphis galls on apple tree roots, and the like; (2) vegetable parasites, as in the club-root and the crown-gall (Fig. 3429); (3) mechanical injury, causing excessive callous development, root-burls, and so on. In addition to these the causes of these enlargements are oftentimes obscure or unknown.

Swellings on the roots of the mulberry are said to be due to the hypertrophy of the lenticels. Some investigators have attributed gall-like root-growths in some instances to the hypertrophy of adventitious buds. The root-galls caused by the nematode (*Heterodera radiculicola*) may usually be readily recognized from other forms of hypertrophied tissue by the numerous knotty enlargements on the smaller roots infested by the worms. By careful search, in most instances, the distended female worms may be found in the infested tissue, where they appear as small nearly spherical pearl-like bodies, readily seen with the unaided eye. This minute worm, commonly called eel-worm, feeds upon the roots of a great variety of cultivated plants and is particularly destructive in the South. It is usually injurious in the northern states only to plants growing under glass. However, ginseng and some other outdoor perennials often suffer severely as far north as Michigan and southern Canada. The most effective remedy in the case of field crops is the removal of all rubbish that would harbor the worms during the winter. In green-houses steam can be forced through the infested soil. When potted plants are badly affected, they may be severely root-pruned and repotted in soil free from worms.

The root-swellings caused by the grape-vine gall-

louse (*Phylloxera vastatrix*) may be readily recognized from other root-galls by the presence of the insects. The young insects, by puncturing the epidermis of the roots and sucking the sap, cause the galls to develop. The insect is found on the diseased roots in all stages of development during the summer.

The most effective method of holding the insect in check appears to be in the use of resistant roots, i. e., the grafting of the more tender varieties on roots of those that are stronger and better able to resist the attack of the insect. Bisulfide of carbon in some instances has proved effective in killing the lice.

The crown-gall appears to be the most harmful of root diseases affecting cultivated plants in this country. These galls have been reported upon the roots of the peach, apricot,

almond, prune, plum, apple, pear, walnut, grape, raspberry, blackberry, cherry, poplar, and chestnut, and without doubt further investigation will find them on other plants as well. The crown-gall disease is now known to be due to a distinct species of pathogenic bacteria (*Bacterium tumefaciens*). It appears to be the same organism in all the host-plants affected by this disease. Seedlings from one to six months old appear to be most susceptible to this disease; hence it is particularly serious in the case of nursery stock. When the galls appear on young trees, they almost always occur on the side of the main root a few inches below the surface of the soil, or in the region of the crown. With more mature trees they are likely to occur at greater depth on lateral roots. At first the gall has a uniform outer appearance, but later it becomes warty from unequal growth. The tissue of the developing gall is soft and succulent, with nodules of woody tissue scattered through it. The galls vary much in size and may reach a diameter of 10 inches.

But little is known as to remedies for crown-gall. As the disease is primarily a nursery disease, the most effective remedy is in securing stock for planting from a non-infested nursery. This disease is often destructive to the roots of roses and asters in the greenhouse benches. Here the destruction of all diseased plants followed by steam sterilization of the soil is the only remedy.

J. W. TOUMEY.

H. H. WHETZEL.†

ROQUETTE, or ROCKET-SALAD (*Eruca sativa*, Mill.), a low-growing hardy annual from southern Europe, whose leaves resemble those of radish and turnip, is much used by the French as a spring and autumn salad and pot-herb. The flavor of the young, tender leaves, which are the parts used, bears a strong resemblance to that of horse-radish. In America it is but little grown because there are milder-flavored plants that serve the same purpose. See *Eruca*.

The first sowing may be made in early spring, the seed being dropped thinly in shallow drills a foot apart, with successional plantings each second or third week through the season. The soil must be rich and well supplied with moisture, else the leaves will probably be tough and acrid. Inter-culture is the same as for spinach, lettuce, and similar crops. Frequent watering and tillage in hot-dry weather to insure rapid vigorous growth should result in succulent mild-flavored leaves. In summer the plants run rapidly to seed; in spring and autumn they will produce abundantly after being cut. The pale citron-yellow flowers emit a perfume resembling that of orange blossoms. M. G. KAINS.

RORIPA (etymology unexplained); originally spelled *Rorippa*, but later emended by its author. *Cruciferae*. Here are included the plants long known as *Nasturtium* (but not the garden flowers of that name, which belong in *Tropaeolum*), and by some later botanists as *Radicula* under which name they are described at page 2895. By a ruling of the International Botanical Congress at Brussels, however, the name *Radicula* is not permissible as it is based on a morphological character; therefore, the plants are transferred (at least temporarily) to *Roripa*. Under *Roripa*, the species become *R. Nasturtium*, Rusby (*Sisymbrium Nasturtium-aquaticum*, Linn. *Radicula Nasturtium-aquaticum*, Brit. & Rend.), the water-cress; *R. Armoracia*, Hitchc. (*Radicula Armoracia*, Rob.), the horse-radish; *R. indica*, Bailey (*Sisymbrium indicum*, Linn. *Nasturtium indicum*, DC.), the tropical cress. L. H. B.

RÒSA (ancient Latin name). *Rosaceæ*. *ROSE*. Ornamental shrubs chiefly grown for handsome flowers, also for ornamental fruits and attractive foliage.

Deciduous or sometimes evergreen, upright, less often climbing or creeping shrubs with usually prickly sts.: lvs. alternate, odd-pinnate, rarely simple, stipulate (Figs. 3430, 3431): fls. solitary or corymbose at the end of usually short branchlets; petals and sepals 5, rarely 4; stamens numerous; pistils numerous, rarely few, inclosed in an urn-shaped receptacle, which becomes fleshy and berry-like at maturity, containing several or many bony achenes, usually erroneously called seeds; the fr. itself is called a "hip." (Figs. 3432, 3433.) *Rosa* is a widespread genus, easily distinguished by well-marked characters from allied genera, but in the limits of the genus itself the characters are exceedingly variable and it is very difficult to group into sections and species the innumerable forms which often pass gradu-

3430. A five-foliolate rose leaf.

ally into each other. In no other genus, perhaps, are the opinions of botanists so much at variance in regard to the number of species. While some, as Bentham and Hooker, estimate the number at about 30, the French botanist Gandoger actually describes from Eu. and W. Asia alone 4,266 species. The larger number of botanists recognize over 100 species. The roses

are almost equally distributed through the colder and temperate regions of the northern hemisphere, in Amer. extending to N. Mex., in Afr. to Abyssinia, and in Asia to India. The fls. show a remarkable tendency to become double, and such forms have been known and cult. from time immemorial. These innumerable garden

forms, increasing every year, are almost exclusively of hybrid origin and are therefore omitted in the botanical classification of the genus.

Many attempts have been made to subdivide the genus with more or less satisfactory results; the more important are those by A. DeCandolle, Lindley, Regel, and Baker. Nowadays the arrangement proposed by Crépin is considered the most natural and satisfactory and has been followed in the account given below. No good general monograph has been published since Lindley's "Monographia Rosarum" (1820), except a rather short one by Regel in 1877. Of the more recent publica-

tions the most important are those of Crépin, especially his "Primitæ Monographiæ Rosarum." In consulting his publications one has to bear in mind that the author changed his opinion somewhat respecting the value of the species during his studies of the genus. In his later publications he takes a broader view in regard to the specific value of the rose forms and unites under one species many forms which he formerly considered as distinct species. An illustrated monograph valuable for the knowledge of the older garden forms and species is Thory and Redouté's "Les Roses," with 160 colored plates (1817-20). It is quoted below as Red. Ros. As the first edition in folio is found in only very few libraries, the smaller edition is cited in parenthesis by volume, groups and the sequence of the plates, neither pages nor plates being numbered continuously in this edition. The most recent book on roses is Miss Ellen Willmott's "The Genus Rosa," with about 150 excellent colored and numerous black plates; in this work all the important species of roses, including most of the recently introduced Chinese species and the types of our cultivated garden forms, are described and figured. It is quoted below as W. R. (with the number of the species).

The economic properties of the rose are of little importance. The most valuable product is attar of roses, a highly fragrant essential oil. It is chiefly manufactured in southeast Europe and western Asia from *Rosa alba* and *R. damascena*, and of late this industry has been successfully transplanted to Germany. See *Perfumery Gardening*, page 2547. The fruits of some species, especially of *R. villosa* and *R. canina*, are made into preserves.

The roses are mostly low or medium-sized shrubs, usually with prickly stems, often more or less stoloniferous, sometimes climbing or creeping, with small or medium-sized odd-pinnate deciduous or evergreen foliage and with mostly large and showy, solitary or clustered flowers ranging in color from purple, crimson, or pink to white and yellow, and followed by ornamental

usually scarlet or bright red fruits remaining on the branches a long time, sometimes through the whole winter. There is probably no flower more popular and better known than the rose. From time immemorial poets have sung its praise, and the love of it can be traced through the most ancient documents in the literature of the Aryan race. It is remarkable to note, however, that the rose has played a far inferior part in the horticulture of the Chinese and Japanese. It is probably the first flower known and cultivated in a double state, and it is the double-flowered garden form whose image the word "rose" almost invariably brings to the mind, while to the wild single-flowered roses much less attention has been given. The ornamental value of single roses is rarely fully appreciated. The wild roses have a simple charm and graceful beauty of their own. No doubt the bold and dominating beauty of the double roses has eclipsed the more modest attractions of the single roses. The longer blooming season of the garden roses is also a factor in their favor. Though the wild roses cannot, perhaps, be compared with their more noble sisters of the garden, they are nevertheless fully able to rival other ornamental shrubs for the adornment of park and plot. Most of the species are hardy or almost hardy North; among the hardiest are *R. rugosa*, *R. virginiana*, *R. carolina*, *R. acicularis*, *R. blanda*, *R. Woodsii*, *R. heliophila*, *R. palustris*, *R. rubrifolia*, *R. pendulina*, *R. canina*, *R. cinnamomea*, and *R. pomifera*. Hardy at least as far north as Massachusetts are *R. spinosissima*, *R. rubiginosa*, *R. multiflora*, *R. Helenæ*, *R. arvensis*, *R. setigera*, *R. gallica*, *R. setipoda*, *R. omeiensis*, while others, as *R. Wichuraiana*, *R. sempervirens*, *R. sericea*, *R. foetida*, *R. hemisphærica*, require some shelter or protection. Hardy only South are *R. Banksiae*, *R. bracteata*, *R. chinensis*, *R. laevigata*, *R. odorata*, *R. stellata*. The recently introduced species from central and western China have not yet been sufficiently tested, but a large percentage appears to be hardy as far north as Massachusetts.

According to the habit peculiar to each species, they can be used for a variety of purposes. Most of the species are shrubby, rarely exceeding 6 or 8 feet, and may be used for borders of shrubberies or for covering slopes and rocky ridges, especially *R. rugosa*, *R. carolina*, and various American species. Some kinds,

3432. Various forms of rose hips. a, *Rosa rugosa*; b, *R. pendulina*; c, *R. carolina*. (About natural size.)

as *R. rugosa* and *R. virginiana*, make handsome ornamental hedges. The climbing species are used for covering walls, trelliswork, arbors, porches, or pillars, but perhaps display their beauty to the most advantage when allowed to ramble over shrubs or rocks. The half-evergreen *R. Wichuraiana* makes a beautiful ground-cover and may also be used for edging groups and flower-beds. The fruits of most species are decorative and

3433. A spray of rose hips.

often remain on the branches all winter. The red stems of most of the species of the *Carolinæ* and *Cinnamomeæ* groups are effective in winter also. The foliage of most of the American species turns purple-orange or yellow in autumn, and so does that of *R. rugosa*, which is, in regard to the foliage with its dark green leathery and glossy leaves, the handsomest of the hardy roses.

With few exceptions the roses are of easy cultivation and grow in almost any kind of soil, except in a loose and very sandy one. They are readily transplanted. The wild roses need little pruning; they should only be thinned out and the weak and old wood be removed; long and vigorous shoots should not be shortened, especially in the climbing varieties, as these shoots are the most floriferous.

All true species can be propagated by seeds, but as roses are likely to hybridize, only seeds taken from isolated plants ought to be used. The hips should be gathered as soon as ripe, the seeds washed out and sown at once or stratified and sown in spring. They germinate the first year, but if kept in the hips during the winter and allowed to become dry, they usually do not germinate until the second year. Mice are very fond of the seeds. Almost all species grow readily from cuttings of nearly ripened wood in summer under glass. Many species, especially the climbing roses, can be propagated by hardwood cuttings taken in fall and planted in spring. Layering is less often practised, except with a few species, like *R. fetida* and *R. hemisphærica*, which do not grow readily from cuttings. Some species, especially those of the groups of *Cinnamomeæ*, *Carolinæ*, and *Gallicæ*, can be increased by root-cuttings; the roots are taken up in fall, stored during the winter in sphagnum or sand in a frost-proof room, and sown in spring in drills and covered about 2 inches deep. The species of the last-named groups and some others are also often increased by suckers and division. Budding and grafting is less often done with the wild roses and should be avoided for roses in shrubberies where the individual plants cannot be carefully watched; the stock usually throws up suckers and outgrows the cion, often in a short time. For general notes on culture and varieties, see *Rose*.

KEY TO THE GROUPS.

(For a horticultural classification of roses, founded primarily on garden values, see the article *Rose*.)

Subgenus HULTHEMIA.

Lvs. simple, without stipules: fls. yellow.

Section I. SIMPLICIFOLIÆ. Species Nos. 1

Subgenus EUROSA.

Lvs. pinnate stipulate.

- A. *Styles exerted beyond the mouth of the receptacle.*
B. *Exserted styles connate into a column, usually as long as stamens. (See Fig. 3434 right.)*
Section 2. SYSTYLÆ. Species Nos. 2-10
BB. *Exserted styles free, about half as long as stamens: fls. usually 3-5.*
Section 3. INDICÆ. Species Nos. 11-14
AA. *Styles reaching only the mouth of the receptacle and stigmas forming a sessile head over it (see Fig. 3434), but slightly exserted in Nos. 63 and 64.*
B. *Stipules free or adnate only at the base, small: sarmentose or climbing shrubs: fls. white or yellow.*

c. Branches glabrous: lfts. 3-5, stipules entire or denticulate.

d. Fls. small, umbellate, yellow or white: pedicels and receptacle smooth: stipules subulate, caducous.

Section 4. BANKSIANÆ. Species Nos. 15, 16

DD. Fls. large, solitary, white: pedicels and receptacle bristly: stipules denticulate.

Section 14. LEVIGATÆ. Species No. 59

CC. Branches tomentose or pubescent: lfts. 7-9; stipules pectinate: fls. 1 or few, white, with large bracts at the base of the short pedicel: receptacle tomentose.

Section 13. BRACTEATÆ. Species No. 58

BB. Stipules adnate more than one-half of their length.

c. Receptacle smooth or hispid.

d. Lvs. of flowering branchlets 3-5-foliolate, large and firm: sts. usually with prickles and bristles: fls. upright, on long pedicels; receptacle bristly; sepals usually pinnate, reflexed after flowering, caducous.

Section 5. GALLICÆ. Species Nos. 17-21

DD. Lvs. of flowering branchlets 5-11-foliolate (rarely 3-foliolate, the fls. then short-pedicelled, with smooth receptacle).

E. Fls. usually corymbose: if solitary, pedicels with 1 or more bracts.

F. Sts. with only one kind of prickles, sometimes mixed with glandular bristles: prickles usually hooked, stout, scattered: outer sepals usually pinnate.

Section 6. CANINÆ. Species Nos. 22-27

FF. Sts., at least at the base, with usually straight often slender prickles and numerous bristles gradually passing into prickles.

G. Sepals after flowering spreading, usually entire, caducous: infl. usually glandular-hispid: fr. usually hispid, with the achenes only at the bottom. (See Fig. 3432, c.)

Section 7. CAROLINÆ.

Species Nos. 28-32

GG. Sepals after flowering upright, usually entire, rarely caducous: fr. usually smooth, with the achenes at the bottom and wall. (See Fig. 3432, a, b.)

Section 8. CINNAMOMÆÆ.

Species Nos. 33-48

EE. Fls. solitary, without bracts, only occasionally corymbose; sepals erect, persistent: lfts. small.

F. Petals 5; styles not exerted.

G. Lfts. usually 9 on the flowering branchlets: prickles straight, usually mixed with bristles and slender: fls. white, pink or yellow; sepals entire.

Section 9. PIMPINELLIFOLIÆ.

Species Nos. 49, 50

GG. Lfts. 5-7 on the flowering branchlets: prickles usually hooked, rather stout: fls. yellow; sepals pinnate, rarely entire.

Section 10. LUTÆÆ. Species Nos. 51, 52

FF. Petals 4, only occasionally 5, white; styles somewhat exerted: lfts. 7-17.

Section 11. SERICÆÆ. Species Nos. 53, 54

CC. Receptacle prickly.

d. Lvs. on flowering branchlets 3-7-foliolate; lfts. cuneate-obovate, incisely dentate.

Section 12. MINUTIFOLIÆ. Species Nos. 55-57

DD. Lvs. of flowering branchlets 7-15-foliolate; lfts. elliptic or elliptic-oblong, sharply serrate.

Section 15. MICROPHYLLÆ. Species No. 60

SUMMARY OF SECTIONS.

Section 1.	SIMPLICIFOLIÆ.....	Species No. 1
Section 2.	SYSTYLÆ.....	Species Nos. 2-10
Section 3.	INDICÆ.....	Species Nos. 11-14
Section 4.	BANKSIANÆ.....	Species Nos. 15, 16
Section 5.	GALLICÆ.....	Species Nos. 17-21
Section 6.	CANINÆ.....	Species Nos. 22-27
Section 7.	CAROLINÆ.....	Species Nos. 28-32
Section 8.	CINNAMOMÆÆ.....	Species Nos. 33-48
Section 9.	PIMPINELLIFOLIÆ.....	Species Nos. 49, 50
Section 10.	LUTÆÆ.....	Species Nos. 51, 52
Section 11.	SERICÆÆ.....	Species Nos. 53, 54
Section 12.	MINUTIFOLIÆ.....	Species Nos. 55-57
Section 13.	BRACTEATÆ.....	Species No. 58
Section 14.	LEVIGATÆ.....	Species No. 59
Section 15.	MICROPHYLLÆ.....	Species No. 60

Subgenus HULTHEMIA.

Section 1. SIMPLICIFOLIÆ. Only one Asiatic species, distinguished from all other roses by the simple exstipulate lvs.

1. *pérstica*, Michx. (*R. simplicifolia*, Salisb. *R. berberifolia*, Pall. *Louea berberifolia*, Lindl.). Low straggling shrub, 2 ft. high, with slender, prickly branches: lvs. short-petioled, oval to oblong, acute at both ends, serrate, bluish green, pubescent, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fls. solitary, yellow, with red eye, about 1 in. across: fr. prickly. June. N. Persia to Siberia. B.M. 7096. B.R. 1261. G.C. III. 6:8, 9, 78. W.R. 1.—This

3434. Section of rose flowers. To show two forms of styles. ($\times \frac{1}{2}$)

peculiar rose is very rare in cult., since it is very difficult to grow. It has been successfully cult. in a cool greenhouse, exposed to the full sun, kept moist during summer and dry from October to March. The only way to prop. it seems to be by suckers; seeds are occasionally intro. from its native country. A hybrid of this species with *R. involucrata* is *R. Hårdii*, Cels., with 5-7-foliolate lvs. and large yellowish white fls., with a deep orange eye. G.C. II. 24:469. Gn. 19, p. 473. P.M. 10:195. W.R. 2.

Subgenus EUROSA.

Section 2. SYSTYLÆ. A group of about 12 species (one of them American), well marked by the styles being connate into a slender exerted column. Sts. sarmentose or climbing, with hooked prickles: fls. in corymbs, few or many; outer sepals pinnate, rarely entire, reflexed after flowering, caducous.

- | | |
|--|---------------|
| A. Stipules pectinate: prickles usually in pairs..... | 2. multiflora |
| AA. Stipules entire or denticulate: prickles scattered. | |
| B. Habit more or less upright with usually arching branches. | |
| C. Lvs. of flowering branchlets 3-5-foliolate, pubescent beneath. | |
| D. Fls. small, $\frac{1}{2}$ in. across: lfts. linear-lanceolate..... | 3. Watsoniana |
| DD. Fls. 2 in. across: lfts. generally ovate-oblong..... | 4. setigera |
| CC. Lvs. of flowering branchlets 5-9-foliolate. | |
| D. Lfts. usually 5-7: corymb paniculate: fr. less than $\frac{1}{2}$ in. long, subglobose. | |
| E. Under side of lfts. pubescent: prickles hooked..... | 5. Brunonii |
| EE. Under side of lfts. glabrous or a few hairs on the midrib: prickles straight or nearly so..... | 6. moschata |
| DD. Lfts. usually 7-9: corymb umbellate: fr. more than $\frac{1}{2}$ in. long, ovoid..... | 7. Helenæ |

BB. *Habit creeping, or prostrate.*

C. *Foliage half-evergreen, lustrous:*

fls. usually several.

D. *Lfts. usually 9, obtuse, $\frac{1}{8}$ – $\frac{3}{4}$ in.*

long.

DD. *Lfts. usually 5, acuminate,*

$\frac{3}{4}$ –2 in. long.

CC. *Foliage deciduous, dull; lfts.*

usually 7; fls. more often solitary. 10. *arvensis*

2. *multiflora*, Thunb. (*R. polyanthos*, Roessig. *R. thyrsoflora*, Leroy. *R. intermedia*, Carr. *R. Wichurae*, Koch). Fig. 3435. Deciduous shrub, with vigorous, long, recurving or climbing branches: lfts. usually 9, obovate to oblong, acute or obtuse, serrate, pubescent, $\frac{3}{4}$ –1 $\frac{1}{3}$ in. long: fls. in many-fl. pyramidal corymbs, usually white, $\frac{3}{4}$ in. across or more; sepals ovate, abruptly acuminate; styles glabrous: fr. small, globular. June. Japan, China. B.M. 7119. G.F. 3:405 (adapted in Fig. 3435); 4:535; 6:316, 317. A.G. 18:677. A.F. 6:1003. Gn. 49, p. 368 (as *R. microcarpa*); 55, p. 432; 66, p. 25. G.M. 44:425 (as *R. polyantha simplex*). B.M. 1059. B.R. 425. G.W. 7, p. 148; 13, pp. 342, 343. Gng. 5:120, 121.—The typical form which is sometimes distinguished as var. *Thunbergiana*, Thory, has small single white fls. and is found in Japan and Korea. Var. *cathayensis*, Rehd. & Wilson. Fls. pink, about 1 $\frac{1}{2}$ in. across, in rather flat corymbs. China. This is the wild single-fl. form from which the two following varieties have been derived. Var. *carnea*, Thory (var. *plena*, Regel. *R. florida*, Poir.). With double light pink fls. B.M. 1059. B.R. 425. Var. *platyphylla*, Thory, with larger lvs. and larger double, deep pink fls. B.R. 1372. This is known as SEVEN SISTERS ROSE. A form of this with intense red and more numerous fls. is the well-known "Crimson Rambler," one of the best climbing roses (Fig. 3436). A.G. 16:233. Many hybrids have originated in cult.; they usually show their parentage by the pectinate stipules. A hybrid with *R. rugosa* is *R. Iwara*, Sieb., with single, rather small white fls. W.R. 61. Of the same parentage is *R. yedoensis*, Makino, with small pink fls. *R. polyantha*, Hort., not Roessig, is a trade name for hybrids with *R. chinensis*. Gn. 29:118. G.C. III. 29:135. G. 27:347. J.H. III. 43:425. The Dawson rose, or *R. Dawsoniana*, is a hybrid with General Jacqueminot. G.W. 7, p. 125. Hybrids with *R. setigera*, *R. gallica*, and *R. Wichuraiana* have also been raised.

3435. *Rosa multiflora* ($\times \frac{1}{2}$)

3. *Watsoniana*, Crépín (*R. multiflora* var. *Watsoniana*, Matsum.). Fig. 3437. Deciduous shrub, with sarmentose or recurving branches: lfts. 3–5, linear-lanceolate, with entire wavy margin, pubescent beneath, 1–2 $\frac{1}{2}$ in. long: fls. in many-fl. pyramidal corymbs, $\frac{1}{2}$ in. across or less, white or pink; style glabrous: fr. small.

3436. Crimson Rambler rose. (See No. 2.)

June, July. R.B. 14, p. 183. G.F. 3:477 (adapted in Fig. 3437). W.R. 16.—A very curious rose of unknown origin, supposed to have been intro. from Japan, but not known in a wild state. Not quite hardy North.

4. *setigera*, Michx. PRAIRIE ROSE. Figs. 3438, 3439. Shrub with prickly branches attaining 6 ft., with long and slender recurving or climbing branches: lfts. 3–5, ovate to oblong-ovate, shortly acuminate, serrate, tomentose beneath, 1–3 in. long: fls. in rather few-fl. corymbs, deep rose, fading to whitish, about 2 in. across, almost scentless; pedicels and receptacle glandular-hispid; style glabrous: fr. globular, $\frac{1}{2}$ in. across. June, July. From Ont. and Wis. to Texas and Fla. Mn. 8:65. G.F. 10:323 (adapted in Fig. 3438). A.G. 13:196, 197; 16:229. Gng. 1:325. C.L.A. 4:339; 7:473. G.W. 7, p. 149. W.R. 23. M.D.G. 1900:423. Var. *tomentosa*, Gray (*R. rubifolia*, R. Br.). Lvs. more tomentose beneath: corymbs with more, but smaller fls. —A valuable hardy climbing rose. Several varieties with double fls. are in cult.; some are probably hybrids with *R. arvensis*, *R. multiflora*, *R. Noisetiana*, and other species.

5. *Brunonii*, Lindl. (*R. Brownii*, Tratt. *R. moschata* var. *nepalensis*, Lindl.). HIMALAYAN MUSK ROSE. Tall shrub, with arching or sarmentose branches, glabrous or thinly villous while young; prickles scattered, hooked, short and stout: lfts. 5–7, elliptic-oblong to oblong-lanceolate, acute or acuminate, serrulate, soft-pubescent beneath, slightly pubescent or nearly glabrous above, 1 $\frac{1}{2}$ –2 $\frac{1}{2}$ in. long; petioles and rachis pubescent, usually with scattered prickles: fls. white, fragrant, 1 $\frac{1}{2}$ –2 in. across, in large many-fl. corymbs; sepals lanceolate, lobed, much longer than receptacle; pedicels long and slender, pubescent and glandular; styles pubescent: fr. ovate, $\frac{1}{8}$ – $\frac{1}{2}$ in. long, glabrous; sepals deciduous. June, July. Himalayas, W. China. B.M. 4030. B.R. 829 F.S. 4:366, 367. Gn. 73, p.

493; 77, p. 511; 79, p. 113 (as *R. moschata*). G. 6:529; 30:419. G.C. III. 36:152, 153. W.R. 10.—A handsome strong-growing rose, but more tender than the real musk rose with which it has been much confused.

6. *moschata*, Mill. (*R. ruscinonensis*, Desv.). MUSK ROSE. Shrub, with arching or sarmentose branches,

3437. *Rosa Watsoniana* ($\times \frac{1}{2}$). No. 3.

glabrous: prickles rather small and slender, straight or slightly hooked: lfts. 5-7, elliptic-ovate to oblong-ovate, acute or acuminate serrulate, glabrous above, hairy on the midrib beneath, otherwise glabrous or nearly so, 1-2 in. long; petioles and rachis nearly glabrous, usually prickly: fls. white, $1\frac{1}{2}$ -2 in. across, fragrant with the odor of musk, in usually 7-fld. corymbs; sepals lanceolate, much longer than the receptacle, lobed, deciduous; pedicels slender, slightly pubescent and glandular; styles pubescent: fr. ovate, small. June, July. S. Eu., N. Afr. W.R. 9. Var. *nastarâna*, Christ (*R. Pissardii*, Carr.). A more robust form: prickles slightly curved: lfts. nearly glabrous beneath: fls. more numerous, over 2 in. across. Persia. R.H. 1880, pp. 314, 315. W.R. 10. Hardier than the type. Var. *abyssinica*, Rehd. (*R. abyssinica*, Lindl.). More prickly and glandular: lfts. smaller, scarcely acuminate: infl. more compact; sepals with smaller lobes or without. Abyssinia. Tender; cult. in Calif.—The musk rose of the older writers, known since the 16th century, seems to have at present almost disappeared from cult.; the plant generally cult. under this name is *R. Brunonii*, which is superior as a garden plant, though it is somewhat tenderer. Several hybrids are known; the most important is *R. Noisetiana*, a hybrid with *R. chinensis* (see No. 13). A hybrid with *R. gallica* is *R. Dupontii*, Déségl. (*R. moschata* var. *nivea*, Lindl.), which differs chiefly in its broader and fewer lfts., the glandular pedicels, the larger fls. with shorter styles and in the presence of bristles on the st. B.R. 861. Gn. 67:254; 77, p. 510. W.R. 13.—*R. moschata densa*, Vilm., belongs probably to *R. Gentiliana* (see suppl. list).

7. *Hélenæ*, Rehd. & Wilson. Sarmentose shrub, to 15 ft.: branches with stout hooked prickles: lfts. usually 7-9, rarely less, oblong-ovate or ovate-lanceolate, short-acuminate, rounded or cuneate at the base, sharply serrate, glabrous above, grayish green beneath and

hairy on the veins, 1-2 in. long: fls. white, fragrant, $1\frac{1}{2}$ in. across, in many-fld. umbel-like corymbs 3-6 in. broad; pedicels slender, about 1 in. long, like the receptacles stipitate-glandular, sepals lanceolate, sparsely pinnate; styles hairy: fr. ovoid or oblong-obovoid, scarlet, about $\frac{1}{2}$ in. long, with deciduous sepals. June. Cent. China.—A handsome free-flowering rose with large clusters of fragrant white fls. in June and scarlet frs. in autumn; has proved hardy at the Arnold Arboretum.

8. *Wichuraiana*, Crépin (*R. Lucie* var. *Wichuraiana*, Koidzumi. *R. bracteata*, Hort., not Wendl.). MEMORIAL ROSE. Fig. 3440. Half-evergreen shrub with prostrate and creeping branches: lfts. roundish or broadly obovate, usually obtuse, serrate, glabrous, shining above, $\frac{1}{3}$ - $\frac{3}{4}$ in. long: corymbs few-fld. or many-fld., pyramidal; fls. white, fragrant, $1\frac{1}{2}$ -2 in. across; styles pubescent; pedicels slightly glandular-hispid: fr. ovoid, to $\frac{1}{2}$ in. high. July-Sept. Japan. B.M. 7421 (as *R. Lucie*). G.F. 4:569 (adapted in Fig. 3440); 6:337. C.L.A. 7:621. G.M. 45:214. Gn. 62, p. 7; 73, p. 164. G.C. III. 22:99. R.H. 1898:105, 106. M.D.G. 1898: 580-5.—A handsome rose for covering banks and rockeries. A number of hybrids, especially with Hybrid Tea roses, have been raised. G.F. 6:337. Mn. 8, pp. 27 and 156. Gng. 6:353-5. Var. *rûbra*, André, with single carmine fls., $1\frac{1}{2}$ -2 in. across, and the lvs. with 5-7 somewhat larger lfts., is a hybrid of *R. Wichuraiana* and *R. multiflora* var. *Crimson Rambler*. R.H. 1901:20. A hybrid with *R. rugosa* is *R. Jacksonii*, Willmott, with bright crimson fls., extremely floriferous and of graceful habit. W.R. 20.

9. *sempervirens*, Linn. Evergreen shrub with long and slender, sarmentose, somewhat reddish branches: lfts. 5-7, ovate-lanceolate, acuminate, serrulate, glabrous, shining above, $\frac{3}{4}$ -2 in. long: fls. in few-fld., rarely many-fld. corymbs, white, to 2 in. across, slightly fragrant; pedicels glandular-hispid; styles usually pubescent: fr. subglobose or ovoid, orange-red. June,

3438. *Rosa setigera* ($\times \frac{1}{2}$). No. 4.

July. S. Eu., N. Afr. B.R. 465. W.R. 5. Var. *prostrata*, Nichols. (*R. prostrata*, Lindl.). Lfts. smaller, oval, acute: fr. ovoid. Var. *scandens*, Nichols. (*R. scandens*, Mill.). Lfts. oblong or oval, obtuse: fr. subglobose. There are some double-fl. garden forms, probably hybrids with *R. chinensis* and other roses. Less hardy than the following.

10. *arvensis*, Huds. (*R. repens*, Scop. *R. silvestris*, Herrm.). Deciduous shrub, with sarmentose or creeping sts.: lfts. usually 7, ovate to ovate-elliptic, acute, serrate, dull above, glabrous or slightly pubescent beneath, rather thin, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long: fls. in few-fl. corymbs, sometimes solitary, white, scentless, $1\frac{1}{2}$ –2 in. across; style glabrous: fr. ovoid. June, July. Eu. B.M. 2054. Gn. 60, p. 233; 77, p. 510. W.R. 3.—A hybrid with *R. chinensis* is *R. ruga*, Lindl., a trailing shrub with large, fragrant double pink fls. in several-fl. corymbs: lfts. ovate, glabrous. B.R. 1389. W.R. 17. Another hybrid is *R. Polliniana*, Spreng. (*R. arvensis* $\times$ *R. gallica*). Upright or sarmentose: lfts. usually 5, large, of firmer texture: fls. long-stalked, large, white to purple. W.R. 111. Here belongs probably the AYRSHIRE ROSE (*R. arvensis* var. *capreolata*, Neill.), with double white to deep pink fls. G.W. 1, p. 355.

Section 3. INDICÆ. Few Asiatic species with upright or procumbent sts.: prickles scattered, hooked, few: lfts. 3–5 rarely 7: infl. 1- to many-fl.; sepals entire or the outer ones sparingly pinnate, reflexed after flowering; bracts and stipules narrow, the latter with small, divergent auricles.

- A. Sts. with uniform prickles: lvs. glabrous.
- B. Lvs. persistent or subpersistent.
- c. Fls. white, yellowish or light pink, very fragrant: fr. globose or depressed-globose; sepals usually entire: stipules without or with few marginal glands at the auricles 11. *odorata*
- cc. Fls. red or pink, rarely whitish, not or slightly fragrant: fr. ovoid or pyriform; sepals usually pinnate: stipules glandular-ciliate. 12. *chinensis*
- BB. Lvs. deciduous: fls. many in a corymb. 13. *Noisettiana*
- AA. Sts. with prickles and bristles: lvs. slightly pubescent beneath: fls. solitary or few. 14. *borbonica*

11. *odorata*, Sweet (*R. indica* var. *odoratissima*, Lindl. *R. Thèa*, Savi. *R. chinensis* var. *fragrans*,

Rehd.). TEA ROSE. Shrub with long sarmentose often climbing branches armed with scattered hooked prickles: lvs. evergreen or half-evergreen; lfts. 5–7, elliptic or ovate to oblong-ovate, acute or acuminate, sharply serrate, lustrous above, glabrous, 1–3 in. long; stipules glandular-ciliate usually only above the middle,

3440. *Rosa Wichuraiana* ($\times \frac{1}{2}$). No. 8.

often sparingly: fls. solitary or 2–3, on rather short, often glandular stalks, white, light pink or salmon. pink, or yellowish, 2– $3\frac{1}{2}$ in. across; sepals entire: fr. globose or depressed-globose, red. W. China. Red. Ros. 1:19 (3:25, 19). B.R. 804.—The original TEA ROSE with double blush fls. was intro. into England in 1810 and in 1824 the form with pale yellow double fls., var. *ochroleuca*, Rehd. (*R. indica* var. *ochroleuca*, Lindl.). Red. Ros. (3:25, 20). From the crossing of the forms of this species between themselves and also with *R. chinensis* the Tea roses of our gardens have originated, while the Hybrid Teas are the offspring of crosses between the Tea roses and other garden roses. Var. *pseud-indica*, Rehd. (*R. chinensis* var. *pseud-indica*, Willmott. *R. Fortuneana*, Paxt., not Lindl.). FORTUNE'S DOUBLE YELLOW. BEAUTY OF GLAZENWOOD. GOLD OF OPHIR. Branches sarmentose, with strongly hooked prickles: lfts. 5–7, elliptic-oblong, firm: fls. 3–4, double, salmon-yellow, sweet-scented, outside tinged with red. B.M. 4679. F.S. 8:769. W.R. 28. Var. *erubescens*, Rehd. & Wilson, has single blush or pale pink fls. and is probably like the following one of the wild forms of the double-fl. garden varieties. *R. chinensis* var. *grandiflora*, Willmott (W.R. 29) is scarcely different. Var. *gigantea*, Rehd. & Wilson (*R. gigantea*, Collett & Hemsl.). Fls. creamy white, single, 4–6 in. across; pedicels and receptacles smooth. Very vigorous, climbing to 50 ft. S. W. China, Burma. G.C. III. 6:13; 37:136; 51:314. Gn. 67, p. 179; 71, p. 67. B.M. 7972. W.R. 34. To this variety *R. macrocarpa*, Watt (*R. xanthocarpa*, Watt) from Manipur, has been referred as a synonym, but the author maintains that it is a distinct species and that it has yellow fls. and edible yellow frs. as large as a small apple.—*R. odorata gigantea* is hardy only S. and is cult. in Calif., where it blooms from Nov. to May. Hybrids with *R. moschata* have been raised by Franceschi at Santa Barbara, Calif.; these are Madeleine Lemoine, Montarioso, and Montecito and they combine the vigor and the foliage of var. *gigantea* with the paniculate infl. of *R. moschata*. Other hybrids with different garden roses have been raised in Eu.

12. *chinensis*, Jacq. (*R. indica*, Lindl., not Linn. *R. chinensis* var. *indica*, Koehne. *R. indica* var. *vulgaris*,

3439. Baltimore Belle rose.—*Rosa setigera* ($\times \frac{1}{2}$). No. 4.

Lindl.). **CHINA ROSE. BENGAL ROSE.** Low upright shrub with slender branches usually armed with scattered stout compressed more or less hooked prickles, sometimes almost unarmed: lfts. 3-5, broadly ovate to ovate-oblong, acuminate, serrate, shining and dark green above and pale beneath, glabrous, 1-2½ in. long; stipules narrow, glandular-ciliate: fls. usually several, less often solitary, on long usually glandular stalks, rarely short-stalked, crimson or pink, rarely whitish, about 2 in. across, not or slightly fragrant; outer sepals usually pinnate: fr. obovoid or turbinate, about ¼ in. long. China. W.R. 26. The wild form recently discovered in Cent. China is var. *spontanea*, Rehd. & Wilson, with single deep red or pink, usually solitary fls. G.C. III. 31:438. The following varieties are garden forms.

Var. *semperflorens*, Koehne (*R. semperflorens*, Curt. *R. bengalensis*, Pers.). **CRIMSON CHINESE ROSE.** Low shrub, with slender, prickly or almost unarmed, dark green branches: lfts. rather thin, mostly stained with purple: fls. usually solitary on slender pedicels, crimson, or deep pink. B.M. 284. W.R. 30.

Var. *longifolia*, Rehd. (*R. longifolia*, Willd.). Lfts. lanceolate: fls. single, deep pink. Red. Ros. (3:25, 8).

Var. *minima*, Rehd. (*R. Laurenciana*, Hort. *R. indica* var. *pumila*, Thory). Dwarf shrub, usually not over 1 ft. high, with small rose-red fls. about 1½ in. across; petals often pointed. There are single- and double-fl. forms. The FAIRY ROSES belong to this variety. B.M. 1762. Red. Ros. (3:25, 6, 7).

Var. *viridiflora*, Dipp. **GREEN ROSE.** With monstrosous green fls.; the petals are transformed into small, narrow green lvs. F.S. 11:1136.

Var. *Manetti*, Dipp. (*R. Manetti*, Hort.). Fig. 3441. Of vigorous growth, upright: pedicels hispid-glandular: fls. deep pink, single or semi-double. This variety has been recommended as a stock for forcing roses; grows readily from cuttings, but is not quite hardy.

3441. The Manetti rose. Much used as a stock ($\times \frac{1}{2}$).
See No. 12.

13. **Noisettiana**, Thory. **NOISETTE ROSE. CHAMPNEY ROSE.** Supposed hybrid of *R. chinensis* and *R. moschata*. Sts. upright to 6 ft., with hooked uniform reddish prickles: lfts. 5-7, usually oblong-lanceolate or oblong-ovate, glabrous: fls. usually many in corymbs, white to pink or red, sometimes yellow; styles pubescent, loosely cohering, protruding beyond the disk. Blooms in summer and fall. Gn. 71, p. 335. W.R. 32. —Numerous garden forms. The Noisette rose was raised about 1816 by John Champney, of Charleston, S. C., from seed of the musk rose fertilized by a blush China rose. From the seed of this hybrid Philippe Noisette,

a florist at Charleston, obtained a rose which was afterward distributed as Blush Noisette by his brother Louis Noisette, of Paris.

14. **borbónica**, Morr. **BOURBON ROSE.** Supposed hybrid of *R. chinensis* and *R. gallica*. Upright shrub, with prickly and often glandular-hispid branches: lfts. usually 7, ovate or ovate-lanceolate, acute, shining, slightly pubescent beneath: fls. 1 or few in a corymb, on glandular pedicels, double or semi-double, usually purple, blooming in summer and fall. W.R. 114. Originated from a rose intro. about 1819 from the Island of Bourbon where it was found among seedlings of the Bengal rose by Mr. Périchon and sent by Mr. Bréon, director of the botanic garden at Bourbon, to Jacques, gardener to the Duke of Orléans at Neuilly near Paris; this rose, called Rose Edward, by crossing with roses of the Gallica groups has given rise to the Hybrid Bourbon roses and is the origin together with crosses between this and other hybrids of *R. chinensis* and its varieties and *R. damascena* of the Hybrid Perpetual or Remontant class.

Section 4. **BANKSIANÆ.** Contains one Chinese species with climbing, sparingly prickly or unarmed sts.: stipules quite free, subulate, caducous: sepals entire, reflexed after flowering, caducous.

A. Pedicels glabrous; fls. small 15. **Banksiæ**
AA. Pedicels hispid; fls. large 16. **Fortuneana**

15. **Banksiæ**, R. Br. **BANKS' ROSE.** Climbing to 20 ft., evergreen: lfts. 3-5, sometimes 7, elliptic-ovate to oblong-lanceolate, acute or obtusish, finely serrate, shining, glabrous except at the base of midrib beneath: fls. on slender, smooth pedicels in many-fl. umbels, white or yellow, about 1 in. across, slightly fragrant. May, June. Cent. and W. China. G.C. III. 31:439. J.H.S. 27:501. Var. *álbo-plèna*, Rehd., with double white fls. B.M. 1954. Var. *lutea*, Lindl. (var. *luteo-plèna*, Rehd.), with double yellow fls. B.R. 1105. Var. *lutescens*, Voss, with single yellow fls. B.M. 7171. Var. *normalis*, Regel, with single white fls. is the wild form.—Intro. first into Eu. by Wm. Kerr, in 1807 in the double white form; the double yellow form was intro. about 1825, while the single white and yellow forms were not known until 40 or 50 years later. Not hardy N.; sometimes grown in greenhouses.

16. **Fortuneana**, Lindl., supposed to be a hybrid of *R. Banksiæ* and *R. laxigata*. Climbing shrub, with sparingly prickly sts.: lfts. 3-5, ovate-lanceolate, lustrous: fls. solitary, large, double, white, on hispid pedicels. F.S. 7, p. 256. J.F. 2, p. 27. W.R. 36.

Section 5. **GALLICÆ.** Contains only one very variable species, native of Eu. and W. Asia. Low, upright shrub: the sts. with usually hooked prickles mixed with bristles: fls. few and often with narrow bracts or solitary on a usually bractless pedicel; sepals reflexed after flowering, caducous, the outer ones pinnate; upper stipules not dilated.

- A. Prickles very unequal: lfts. usually doubly and glandular-serrate.
- B. Texture of lfts. firm, leathery: pedicels upright..... 17. **gallica**
- BB. Texture of lfts. thin; lfts. sometimes simply serrate: fls. nodding, usually double..... 18. **centifolia**
- AA. Prickles uniform: lfts. simply serrate, not glandular. (Supposed hybrids of *R. gallica*.)
- B. Prickles numerous.
- C. Receptacle glandular-hispid: lfts. ovate-oblong, often pubescent beneath..... 19. **damascena**
- CC. Receptacle usually smooth: lfts. broadly ovate or broadly elliptic, pubescent beneath..... 20. **alba**
- BB. Prickles sparse, on the flowering branchlets nearly wanting: lfts. glabrous beneath or pubescent only on the midrib..... 21. **francofurtana**

17. *gállica*, Linn. Upright shrub, with creeping rootstock, rarely attaining 5 ft. high: sts. usually densely covered with prickles and bristles: lfts. 3-5, leathery, broadly oval or ovate, rounded at base, usually doubly serrate with glandular teeth, rugose above, pubescent beneath, deflexed, 1-2 in. long; rachis glandular-pubescent and often prickly: fls. on rather stout, upright,

3442. *Rosa centifolia* var. *muscosa*.—Moss rose. ($\times \frac{1}{2}$)

glandular-hispid and bristly pedicels, deep pink to crimson, 2-3 in. across; receptacle glandular-hispid: fr. subglobose or turbinate, brick-red. June. Cent. and S. Eu., W. Asia. G.W.H. 1:89.—The following are the most important forms: Var. *Agatha*, Thory. With rather small, very double purple fls., the outer petals spreading, the inner ones concave. Red. Ros. (2:17, 17-21). Var. *incarnata*, Rehd. (*R. incarnata*, Boreau, not Mill.). Lfts. narrower, elliptic-ovate to elliptic-oblong: rachis not prickly; flowering branches unarmed: fls. large, pale crimson, solitary: fr. ovoid. B.M. 7035. Var. *macrantha*, Hort., similar to the preceding, but fls. pale pink, finally white. Gn. 52:464. G. 29:417. R.H. 1901:548. Var. *officinalis*, Thory (*R. provincialis*, Mill. Var. *plena*, Regel), is like the typical form but with double fls. W.R. 121.

Var. *versicolor*, Thory. ROSA MUNDI; also YORK AND LANCASTER ROSE. Petals striped white and red. W.R. 110. Red. Ros. (2:16, 12). Var. *pumila*, Braun (*R. austriaca*, Crantz). Dwarf form, with creeping rootstock: fls. red, single. Red. Ros. (2:17, 2).

18. *centifolia*, Linn. (*R. gállica* var. *centifolia*, Regel). CABBAGE ROSE. Closely allied to the preceding species. Rootstock less creeping: prickles stouter: lfts. usually 5, pubescent on both sides or only beneath, larger and thinner; rachis not prickly: fls. usually pink, very double, on long and slender pedicels, nodding, fragrant; petals inflexed; sepals persistent. June, July. E. Caucasus. W.R. 115. G. 1:340. Of this rose the double-flowered form only is in cult., known already to the ancients. Var. *muscosa*, Sér. (*R. muscosa*, Ait.). Moss ROSE. Fig. 3442. Fls. rose, with peduncles and calyx glandular-mossy. B.M. 69. Gn. 18:84. G.W. 7, p. 125. Var. *álbo-muscosa*, Willmott. Like the preceding, but fls. white. B.R. 102. W.R. 117. Var. *cristata*, Prévost, has the mossy excrescences confined to the edges of the sepals. B.M. 3475. G.W. 7,

p. 125. W.R. 118. Var. *pompônia*, Lindl. (*R. pulchella*, Willd. *R. dijonensis*, Roessig). POMPON ROSE. Dwarf form: lfts. elliptic, glabrous above, about 1 in. long: fls. double, bright red, $1\frac{1}{2}$ in. across; pedicels densely setose. W.R. 119. Var. *parvifolia*, Rehd. (*R. parvifolia*, Ehrh. *R. burgundica*, Roessig). BURGUNDIAN ROSE. Similar to the preceding, but smaller: lfts. $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. about 1 in. across; pedicels slightly setose. B.R. 452. W.R. 120.—Numerous spontaneous hybrids are known. From this with its varieties, and *R. damascena*, the Hybrid Perpetual or Remontant roses have originated by hybridizing with *R. chinensis* and its forms.

19. *damascena*, Mill. (*R. bifera*, Pers. *R. calendarrum*, Borkh.). DAMASK ROSE. Attaining 5 ft.: sts. usually with numerous stout and hooked prickles, sometimes mixed with glandular bristles; lfts. usually 5, sometimes 7, ovate-oblong, serrate, more or less pubescent beneath, 1-2½ in. long; stipules scarcely dilated, sometimes pectinate; petioles prickly: fls. usually corymbose, double, red, pink or white, sometimes striped; pedicels and receptacles glandular-hispid; sepals deciduous, reflexing during flowering-time: fr. obovate. June, July, and again in autumn. Red. Ros. (2:16, 6). W.R. 124. Origin unknown: intro. to Eu. from Asia Minor in the 16th century. Var. *trigintipetala*, Dieck, with semi-double red fls., is considered to be the rose chiefly cult. in S. E. Eu. for the manufacturing of attar. Gt. 38, p. 129. G.C. III. 7:45.

20. *álba*, Linn. Upright shrub, becoming 6 ft. high: sts. with scattered hooked prickles and sometimes with bristles: lfts. usually 5, broadly ovate or broadly elliptic, serrate, pubescent beneath, 1-2 in. long; upper stipules dilated: fls. more or less double, usually several, white, fragrant; pedicels glandular-hispid; receptacle usually smooth: fr. ovate, scarlet. June. Origin unknown, probably hybrid of *R. gállica* and *R. dumetorum*. Var. *rubicunda*, Roessig (*R. incarnata*, Mill. *R. álba* var. *incarnata*, Pers.). Fls. double, white tinged with pink. W.R. 137.

21. *francofurtana*, Muenchh. (*R. turbinata*, Ait.). Upright shrub, attaining 6 ft.: sts. with straight or hooked prickles: flowering branches almost unarmed: lfts. 5-7, oval, serrate, pubescent beneath; upper stipules much dilated: fls. 1-3, single or double, purple, 2-3 in. across, slightly fragrant; pedicels and receptacle glandular-hispid only at the base; sepals erect after flowering, entire or nearly so: fr. turbinate. June.

3443. *Rosa palustris* ($\times \frac{1}{2}$). No. 28.

Supposed hybrid of *R. gallica* and *R. cinnamomea*. Red. Ros. (3:23, 1).

Section 6. CANINÆ. Many species in Eu., N. Afr. and W. Asia. Upright shrubs, with scattered, usually hooked and numerous prickles; upper stipules dilated; corymb usually many-fl'd., with dilated bracts; outer sepals pinnate, reflexed after flowering and caducous or erect and persistent.

- A. Lvs. pubescent, at least beneath, or glandular.
- B. Prickles slender, straight or slightly curved.
 - c. Lfts. large, to 2 in. long: fr. large, to 1 in. across.....22. **pomifera**
 - cc. Lfts. smaller: branchlets purple, bloomy: fr. smaller.....23. **mollis**
- BB. Prickles hooked, stout.
 - c. Under side of lfts. glandular.....24. **rubiginosa**
 - cc. Under side of lfts. pubescent.....25. **dumetorum**
- AA. Lvs. glabrous.
 - B. Foliage bright or dark green.....26. **canina**
 - BB. Foliage bluish green, tinged with red.27. **rubrifolia**

22. **pomifera**, Herrm. (*R. villosa*, Linn., in part). Upright, densely branched shrub, attaining 6 ft., with almost straight spines: lfts. 5-7, oval to ovate-oblong, acute or obtuse, doubly glandular-serrate, grayish green, pubescent above, tomentose beneath, rarely glabrescent, 1-2 in. long: fls. 1-3, pink, 1½-2 in. across, on bristly and glandular pedicels: fr. scarlet, ovoid or subglobose, to 1 in. across, hispid, with persistent erect sepals. June, July. Eu., W. Asia. B.M. 7241. W.R. 141.—Hardy rose, with large ornamental fr.

23. **mollis**, Smith (*R. villosa* var. *mollissima*, Rau). Upright shrub, to 4 ft.: branchlets purple, more or less bloomy; prickles sometimes ½ in. long: lfts. 5-7, broadly oval, rarely oval-oblong, doubly serrate, pubescent

above, tomentose and usually silky beneath, 1½-1¾ in. long: fls. 1-3, 1½-2 in. across, deep pink, rarely white; pedicels usually only sparingly glandular: fr. small, glabrous or stipitate-glandular. June. Eu., W. Asia. W.R. 138.

24. **rubiginosa**, Linn. (*R. Eglanteria*, Linn.). SWEETBRIAR. EGLANTINE. Dense shrub, attaining 6 ft., with hooked prickles often mixed with bristles: lfts. 5-7, orbicular to oval, doubly glandular-serrate, dark green above and glabrous, pale beneath and often pubescent, glandular on both sides, 1½-1¾ in. long: fls. 1-3, on hispid short pedicels, bright pink, 1½-2 in. across; receptacle usually glandular-hispid: fr. subglobose or ovoid, orange-red to scarlet, with upright-spreading, usually caducous sepals. June. Eu.; naturalized in some localities in the East. B.B. (ed. 2) 2:286. W.R. 145.—A handsome hardy rose of compact habit, with bright green foliage exhaling a very agreeable aromatic odor. There are some double forms and hybrids with other species.

3445. *Rosa foliolosa*. (×½)

25. **dumetorum**, Thuiller. Upright shrub with spreading or recurving branches with stout hooked prickles: lfts. 5-7, close, oval-orbicular to elliptic, usually simply serrate, pubescent on both sides or only below on the veins, 1-1½ in. long: fls. solitary to many, about 2 in. across; pedicels glabrous or stipitate-glandular: fr. ovoid to subglobose, orange-red, about ¾ in. long, usually glabrous. June. Eu., W. Asia, N. Afr. W.R. 132.—Very close to the following species and chiefly distinguished by the pubescence.

26. **canina**, Linn. Dog Rose. Upright shrub, attaining 10 ft. or more, with often recurving branches: prickles stout, hooked: lfts. 5-7, oval or elliptic, doubly serrate, glabrous or slightly pubescent or somewhat glandular beneath, ¾-1½ in. long: fls. 1-3, light pink, on usually glabrous pedicels; sepals reflexed, caducous: fr. ovate, orange-red, or scarlet, glabrous. June. Eu., N. Afr., W. Asia; naturalized in some localities. W.R. 126. B.B. (ed. 2) 2:284.—Much used as stock for grafting. Var. *exilis*, Keller (*R. exilis*, Crépin). Low form with small lfts. about ½ in. long, and small pink fls. about 1 in. across. W.R. 127.

27. **rubrifolia**, Vill. (*R. glauca*, Pourr. A. *jeruginea*, Deségl., not Vill.). Upright shrub, attaining 6 ft., with slender, purplish branches covered with glaucous bloom: prickles few, hooked or straight: lfts. 7-9, elliptic or ovate-lanceolate, simply serrate, bluish green and more or less tinged with red, ¾-1½ in. long: fls. 1-3 or more, pink, 1½ in. across, on usually hispid-glandular pedicels; sepals long, with dilated apex, upright-spreading, tardily caducous: fr. subglobose, scarlet. June. Mountains of Cent. and S. Eu. B.R. 430. G.W. 7, p. 139. W.R. 133.—A very striking rose on account of its reddish foliage: fls. less conspicuous. Hardy North and prefers partial shade.

3444. *Rosa carolina* var. *triloba* (×¾) No. 30.

Section 7. CAROLINÆ. Contains only American species.

Upright, mostly low shrubs: sts. slender, with usually straight prickles, placed in pairs and often mixed with bristles: upper stipules usually narrow: corymbs generally few-fl.; sepals spreading after flowering, caducous, the outer ones entire or with few erect lobes: achenes inserted exclusively at the bottom of the usually depressed-globose receptacle.

- A. Pedicels rather long: lfts. 5-9.
- B. Lfts. finely many-toothed: prickles usually hooked: stipules convolute. 28. *palustris*
- BB. Lfts. coarsely toothed: prickles usually straight and slender: stipules flat.
- C. Branches prickly only at the nodes or unarmed, only vigorous shoots bristly.
- D. Prickles hooked: lfts. shining above. 29. *virginiana*
- DD. Prickles straight or nearly so: lfts. dull above. 30. *carolina*
- CC. Branches densely bristly. 31. *nitida*
- AA. Pedicels very short: lfts. 7-11, small and narrow. 32. *foliolosa*

28. *palustris*, Marsh. (*R. carolina*, Auth., not Linn. *R. corymbosa*, Ehrh. *R. pennsylvanica*, Michx.). Fig. 3443. Upright shrub, attaining 8 ft., with slender sts.: lfts. usually 7, elliptic to narrow-oblong, acute at both ends, usually pubescent beneath, $\frac{3}{4}$ -2 in. long; stipules narrow: fls. usually corymbose, pink, about 2 in. across: fr. depressed-globose, glandular-hispid, about $\frac{1}{2}$ in. high, like those of the following species. June-Aug. Nova Scotia to Minn., south to Fla. and Miss., preferring swampy and moist ground. Em. 2:488. B.B. (ed. 2) 2:285. W.R. 1:68. Mn. 1, p. 86. Var. *Nuttalliana*, Hort., has larger fls. appearing later and continuing until Sept.

29. *virginiana*, Mill. (*R. lucida*, Ehrh. *R. humilis* var. *lucida*, Best). Shrub, 6 ft. high, with few or no suckers: prickles sometimes hooked: lfts. 7-9, elliptic to obovate-elliptic, dark green and shining above, thickish, often slightly pubescent beneath, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long; stipules somewhat dilated: fls. usually few or solitary, about 2 in. across; sepals usually entire: fr. like that of the preceding. June, July. Newfoundland to N. Y. and Pa. B.B. (ed. 2) 2:285. Gn. 55, p. 428; 71, p. 493. Gt. 56:1564, fig. 2. W.R. 63.—Well adapted for borders of shrubberies, handsome in summer with its shining foliage and bright pink fls.; ornamental in winter with the brownish red sts. and red frs. remaining plump until the following spring. Var. *alba*, Willmott.

3446. Semi-double
Rosa rugosa ($\times \frac{1}{2}$).
No. 33.

has white fls. and green sts. A.F. 12:1098. Gng. 5:306. M.D.G. 1904:205. W.R. 63a. Var. *plena*, Hort. (*R. rāpa*, Bosc). With double fls.

30. *carolina*, Linn. (*R. humilis*, Marsh. *R. parviflora*, Ehrh. *R. virginiana* var. *humilis*, Schneid. *R. Lyoni*, Pursh). Fig. 3432. Shrub, 3 ft. or sometimes 6 ft. high, spreading by means of numerous suckers, with slender prickles and usually numerous bristles: lfts. 5-7, resembling those of the former, but narrower, thinner, not shining, usually pubescent beneath: fls. often solitary; outer sepals lobed. June. Maine to Ga., west to Wis. and Okla. W.R. 64.—Much resembling the preceding, which is often considered a variety of this species. Var. *villōsa*, Rehd. (*R. humilis* var. *villōsa*, Best). Lvs. villous-pubescent beneath, thickish. Var. *grandiflora*, Rehd. (*R. humilis* var. *grandiflora*, Baker). Fls. 2 in. across: lfts. larger. W.R. 66. Var. *triloba*, Rehd. (*R. humilis* var. *triloba*, Wats.). Fig. 3444. Petals 3-lobed. G.F. 2:77 (adapted in Fig. 3444).

3447. Fruits of *Rosa rugosa*. ($\times \frac{1}{4}$)

31. *nitida*, Willd. Low upright shrub, 1 $\frac{1}{2}$ ft. high: branches covered with straight prickles and numerous bristles: lfts. 7-9, narrowly oblong, acute at both ends, bright green and shining above, glabrous, $\frac{1}{2}$ -1 in. long: fls. usually solitary, 1-2 in. across, on slender glandular-hispid pedicels; sepals entire. June, July. Newfoundland to Mass. B.B. (ed. 2) 2:285.

32. *foliolosa*, Nutt. Fig. 3445. Low shrub, 1 $\frac{1}{2}$ ft. high: sts. with rather few slender prickles, sometimes almost unarmed: lfts. 7-9, narrow or linear-oblong, bright green and shining above, glabrous or pubescent on the midrib beneath, $\frac{1}{2}$ -1 in. long: fls. solitary or few, pink, about 1 $\frac{1}{2}$ in. across; pedicels and receptacle smooth or sparingly glandular-hispid: fr. globose, with rather few achenes. May, June. Ark. and Okla. to Texas. G.F. 3:101 (adapted in Fig. 3445).—Like the preceding, a handsome dwarf shrub with graceful foliage.

Section 8. CINNAMOMEÆ. Many American, Asiatic, and European species. Erect shrubs, with usually straight prickles, in pairs or scattered, and often with numerous bristles: lfts. 5-11: corymbs usually many-fl., with dilated bracts; sepals generally entire, upright after flowering, and persistent, rarely deciduous: receptacle usually smooth.

- A. Branches and prickles tomentose. 33. *rugosa*
- AA. Branches and prickles glabrous.
- B. Stipules, at least on the shoots, more or less convolute. 34. *cinnamomea*
- BB. Stipules flat.
- C. Prickles nearly always wanting (sometimes present in No. 37).
- D. Lfts. simply serrate, 5-7.
- E. Rachis of lf. puberulous: fls. single. 35. *blanda*
- EE. Rachis of lf. glabrous: fls. double. 36. *Lheritierana*
- DD. Lfts. doubly serrate, 7-9: fr. oblong to ovoid. 37. *pendulina*
- CC. Prickles present.
- D. Lfts. 3-7, only on shoots occasionally 9: calyx persistent.
- E. Upper stipules enlarged.
- F. Fls. usually several, 1-2 in. across: lfts. generally obovate, $\frac{1}{2}$ -1 $\frac{1}{2}$ in. long. 38. *Woodsii*
- FF. Fls. usually solitary, about 2 in. across or more: lfts. 1-2 in. long.

- G. Flowering branchlets usually unarmed: lfts. generally ovate.....39. *nutkana*
 GG. Flowering branchlets prickly: lfts. generally oblong.....40. *acicularis*
 EE. Upper stipules narrow, like the lower.
 F. Prickles hooked: lfts. doubly serrate.....41. *californica*
 FF. Prickles straight, usually slender: lfts. usually simply serrate.....42. *pisocarpa*
 DD. Lfts. 7-11.
 E. Sepals persistent.
 F. Fls. corymbose; sepals pinnate or serrate.
 G. Shrub 1-2 ft.: sts. with numerous slender prickles.....43. *heliophila*
 GG. Shrub to 10 ft.: sts. with paired stout wide-based prickles.....44. *setipoda*
 FF. Fls. 1-3; sepals entire.
 G. Lfts. 1-2 in. long, pubescent beneath: fls. 1-3. 45. *macrophylla*
 GG. Lfts. $\frac{1}{4}$ -1 $\frac{1}{4}$ in. long, glabrous or nearly so beneath: fls. usually solitary, short-stalked. 46. *Moyesii*
 EE. Sepals with their base falling off as a whole: fls. solitary on short lateral branchlets: lfts. 5-9, $\frac{1}{4}$ -1 in. long.
 F. St. with bristles and prickles: lfts. doubly serrate, $\frac{1}{2}$ -1 in. long.....47. *gymnocarpa*
 FF. Sts. without bristles: lfts. simply serrate.....48. *Willmottiae*

33. *rugosa*, Thunb. (*R. ferox*, Lawr. *R. Regeliana*, André & Lind. *R. coruscans*, Waitz). Figs. 3446-3448.

3449. Bud of Madame Georges Bruant rose. One of the *rugosa* hybrids ($\times \frac{1}{4}$). No. 33.

Upright shrub, attaining 6 ft., with stout sts. densely beset with prickles and bristles: lfts. 5-9, oval to obovate-oval, rugose, shining and dark green above, glaucescent and pubescent beneath, thick and firm, $\frac{3}{4}$ -2 in. long; petioles tomentose and bristly; stipules dilated: fls. solitary or few, purple or white, $2\frac{1}{2}$ -3 $\frac{1}{2}$ in. across;

3448. *Rosa rugosa* ($\times \frac{1}{2}$). No. 33.

bracts large; pedicels prickly; receptacle smooth: fr. depressed-globose, brick-red, to 1 in. across. May-Sept. N. China, Korea, Japan. S.Z. 1:28. B.R. 420. Gt. 30:1049; 42, p. 537. G.C. II. 14:372. Gn. 46, p. 324; 52:384; 55, p. 434. I.H. 18:47. Gng. 1:7; 5:339. A.G. 13:342, 344; 18:567. C.L.A. 2:76; 7:624. F.E. 18:6. J.H. III. 45:159.—Forms of typical *R. rugosa*, which is sometimes distinguished as var. *Thunbergiana*, C. A. Mey., are the following: Var. *alba*, Rehd. (var. *albiflora*, Koidzumi), with white fls. Gn. 9:452. G. 8:261. Var. *albo-plena*, Rehd., with double white fls. Var. *rosea*, Hort., with pink fls. Var. *rubra*, Hort., with purple fls. Var. *rubro-plena*, Rehd., with double purple fls. Gt. 24:846. Geographical varieties, not of garden origin, are the following two: Var. *Chamissoniana*, C. A. Mey. (*R. pubescens*, Baker, not Roxbg.). Bristles almost entirely absent on the branches: lfts. narrower and smaller, less rugose. A double-fl. form of this variety is sometimes cult. in Cent. China, but apparently not yet intro. into western gardens. Var. *kamschatica*, Regel (*R. kamschatica*, Vent.). With slenderer less densely armed branches, thinner less rugose lvs. and smaller fls. and frs. B.M. 3149. B.R. 419.—*Rugosa* is one of the most ornamental and at the same time hardiest of the single roses, valuable for shrubberies; it is very handsome on account of its dark green shining foliage, large fls. appearing during the whole summer, bright red conspicuous frs., and its beautiful orange and scarlet fall coloring. It is also attractive in winter by reason of its stout, densely armed sts. Large numbers of hybrids have been raised. By crossing with double-fl. garden roses, *R. rugosa* has given rise to a new race of hybrid roses remarkable for their hardiness and long blooming season; one of the best known is Mme. Georges Bruant (Fig. 3449), with double white fls., a cross of *R. rugosa* and the Tea rose Sombreuil. Another cross with a form of *R. chinensis* is *R. calocarpa*, Willmott (*R. rugosa* var. *calocarpa*, Bruant), with single rose-colored fls. and handsome fr. produced very abundantly. Gn. 46, p. 548; 52, p. 384. R.H. 1895, pp. 446, 447. I.H. 42, p. 15. W.R. 60. Remarkable for its large frs. and large fls. is *R. microgosa*, Henkel (*R. rugosa* $\times$ *R. microphylla*. *R. Vilmorinii*, Bean). Upright, very spiny shrub: lfts. 7-11, small, pubescent: fls. pink, 3-4 in. across: fr. depressed-globose, about 1 $\frac{1}{4}$ in. across, prickly, orange-red. Gt. 59:1581. R.H. 1905:144. It is of vigorous growth and hardy and will probably make a good hedge plant. Hybrids are also known with *R. multiflora* (see *R.*

Iwara under No. 2), with *R. Wichuraiana* (see *R. Jacksonii* under No. 3), with *R. cinnamomea*, with *R. spinosissima*, with *R. carolina*, a pretty rose with purplish red fls. (W.R. 65), with *R. blanda*=*R. warleyensis*, Willmott, a handsome rose with pink fls. and 5-7 small lfts. (W.R. 59), with *R. palustris*=*R. Spaethiana*, with large purple corymbose fls. (Gt. 51:1504, 3), and there are probably others.

34. *cinnamomea*, Linn. CINNAMON ROSE. Sts. slender, 6 ft. high, with hooked prickles, flowering branches sometimes unarmed: lfts. 5-7, sometimes 3, on lvs. of flowering branchlets, oblong, simply serrate, dull green, densely pubescent beneath, $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. solitary or few, purple, about 2 in. across, on short, naked pedicels: fr. depressed-globular, scarlet. May, June. Eu., N. and W. Asia. A.G. 13:343. W.R.

45. Var. *foecundissima*, W. D. Koch (*R. foecundissima*, Muenchh.). Figs. 3450, 3451. With double fls. Sometimes escaped from cult. in the East.

3450. *Rosa cinnamomea* var. *foecundissima*.

35. *blanda*, Ait. (*R. virginiana*, Koehne, not Mill. *R. fraxinifolia*, Borkh.). Sts. slender, 5 ft. high, with few slender prickles or unarmed: lfts. 5-7, elliptic to obovate-oblong, usually acute, simply serrate, glabrous or pubescent beneath, $\frac{1}{2}$ - $2\frac{1}{2}$ in. long; stipules dilated: fls. usually several, pink, 2- $2\frac{1}{2}$ in. across, on smooth peduncles: fr. globular, sometimes elongated: May, June. Newfoundland to N. Y., west to Wis. and Ill. B.B. (ed. 2) 3:283. W.R. 104. Var. *Willmottiae*, Baker. Sts. red: lfts. smaller: fls. bright coral-pink. W.R. 104, 3.

36. *Lheritierana*, Thory (*R. reclinata*, Thory. *R. Boursaultii*, Hort.). Supposed hybrid of *R. pendulina* and *R. chinensis*. Climbing to 12 ft., with slender, sparingly prickly branches: lfts. 3-7, oblong-ovate, glabrous: fls. in corymbs, purple, double or semi-double, nodding: fr. subglobose, smooth. Red. Ros. (3:26, 3). W.R. 102.—Varying with lighter and deeper colored and more or less double fls.

37. *pendulina*, Linn. (*R. alpina*, Linn.). Fig. 3432. Sts. slender, 3 ft. high, usually nearly unarmed, rarely prickly and bristly: lfts. 7-9, oblong-ovate or oblong-elliptic, obtuse, doubly glandular-serrate, usually gla-

brous, $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. pink, usually solitary or 2-5, to 2 in. across; pedicels and receptacle usually smooth: fr. usually nodding, oblong or ovate, with elongated neck, scarlet. May, June. Mountains of Eu. B.R. 424. J.H. III. 43:9. W.R. 99.—Handsome free-flowering shrub. Var. *pyrenæica*, W. D. Koch (*R. pyrenæica*, Gouan). Dwarf, with the pedicels and usually also the receptacles glandular-hispid. B.M. 6724. Gn. 27:544. Possibly a hybrid of this species and *R. spinosissima* is *R. Malyi*, Kerner, similar in foliage to *R. spinosissima*, but with bright red fls. W.R. 100; one of the handsomest of the wild roses.

38. *Woodsi*, Lindl. Sts. to 3 ft. high, with slender, straight or recurved prickles, often bristly: lfts. 5-7, or sometimes 9 on shoots, obovate to oblong, mostly simply serrate, usually pubescent beneath, $\frac{3}{4}$ - $1\frac{1}{2}$ in. long: fls. corymbose or solitary, pink, rarely white, $1\frac{1}{2}$ -2 in. across, on very short smooth pedicels: fr. globose, with short neck. June, July. Sask. to Colo. and Mo. B.R. 976. B.B. (ed. 2) 2:284. W.R. 77. Var. *Fendleri*, Rydb. (*R. Fendleri*, Crépín). Slenderer and often taller: lfts. usually smaller, usually doubly glandular-serrate, often glabrous, fls. and fr. somewhat smaller. Brit. Col. to W. Texas and New Mex. W.R. 56.

39. *nutkana*, Presl. Fig. 3452. Sts. stout, 5 ft. high, with usually straight prickles and sometimes bristly: lfts. 5-7, or sometimes 9 on shoots, broadly elliptic to oblong-lanceolate, generally rounded at the base, usually doubly glandular-serrate, almost glabrous, often glandular beneath, $\frac{1}{2}$ -2 in. long: fls. usually solitary, pink, 2- $2\frac{1}{2}$ in. across: fr. globose, without neck. June, July. Alaska to Ore. and Utah. G.F. 1:449 (adapted in Fig. 3452). W.R. 75.—Has the largest fls. of the western species; pink. Var. *hispida*, Fern., has the receptacle glandular-hispid.

40. *acicularis*, Lindl. Sts. low, densely prickly: lfts. 3-7, broadly elliptic to narrowly oblong, rounded at base, simply or doubly serrate, pubescent beneath, $\frac{1}{2}$ -2 in. long: fls. solitary, deep rose, $1\frac{1}{2}$ -2 in. across, fragrant; sepals entire and nearly glabrous: fr. usually pyriform, $\frac{1}{2}$ -1 in. long. May, June. Alaska to Ont. and Colo., N. Eu., N. Asia, Japan. B.B. (ed. 2) 2:283.—A very variable species. Var. *Bourgeauiana*, Crépín (*R. Sâyi*,

3451. *Rosa cinnamomea* var. *foecundissima*. One of the old-fashioned hardy roses. ($\times \frac{1}{2}$)

Schwein. *R. acicularis* var. *Sâyi*, Rehd.). Fig. 3453. Lfts. glandular and pubescent beneath, usually somewhat doubly glandular-serrate: fls. larger, often $2\frac{1}{2}$ in. across: fr. usually globular. Ont. to Brit. Col. and Colo. Var. *Engelmannii*, Crépín in herb. (*R. Engelmanni*, Wats.). Fig. 3454. Similar to the preceding: lfts. distinctly doubly glandular-serrate: fr. oblong, to 1 in. long. Colo. to Brit. Col. G.F. 2:377 (adapted in Fig. 3454). Var. *nipponensis*, Hook. f. Lfts. smaller, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; petioles bristly: branchlets and

3452. *Rosa nutkana*. ($\times \frac{1}{4}$)

pedicels glandular-hispid: fls. $1\frac{1}{2}$ in. across. Japan. B.M. 7646. W.R. 47.

41. *californica*, Cham. & Schlecht. Sts. 8 ft. high, with stout, hooked or straight prickles, often bristly: lfts. 5-7, broadly elliptic to oblong-obovate, simply or doubly glandular-serrate, pubescent beneath or on both sides, often glandular, $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. on slender, usually smooth pedicels, over 1 in. across, few or several in dense corymbs, pink: fr. globose-ovate, usually with a prominent neck. June-Aug. Brit. Col. to Calif. W.R. 72 (a semi-double form).

42. *pisocarpa*, Gray. Sts. thin, with slender, straight or ascending prickles, without bristles, sometimes unarmed: lfts. 5-7, oblong to oblong-obovate, acute or obtuse, simply serrate, pubescent or sometimes glabrous beneath, $\frac{1}{2}$ - $1\frac{1}{2}$ in. long: fls. pink, about 1 in. across, on short usually smooth pedicels, in several- to many-fl. corymbs: fr. globose, with a very short neck. June-Aug. Brit. Col. to Ore. B.M. 6857.

43. *heliophila*, Greene (*R. pratincola*, Greene, not H. Braun). Low shrub, to 2 ft.: sts. very prickly, usually green: lfts. 7-11, broadly elliptic to obovate-oblong, acute or obtuse, cuneate at the base, simply serrate, pubescent beneath at least on the veins, 1 - $1\frac{1}{4}$ in. long; stipules rather narrow, entire or glandular-toothed above: fls. corymbose, pink, 1 - $1\frac{1}{2}$ in. across; pedicels and receptacle glabrous; outer sepals lobed: fr. globose, $\frac{1}{2}$ - $\frac{1}{2}$ in. across, red June. Man. to Mont., south to Mo. and Texas, prairies. B.B. (ed. 2) 2:284. Mn. 3:116. W.R. 105.—Adapted for dry slopes and barren places. Var. *alba*, Rehd. With white fls. about 2 in. across.—*R. pratincola* has been confused with *R. arkansana* and is sometimes cult. under the latter name. The true *R. arkansana*, Porter, differs in its glabrous foliage, glandular and bristly stipules, and reflexed sepals; it is known only from Colo.

44. *setipoda*, Hemsl. & Wilson (*R. macrophylla* var. *crasseaculeata*, Vilm.). Shrub, to 10 ft.: branches with paired straight, wide-based prickles: lvs. $2\frac{1}{2}$ -7 in. long; lfts. 7-9, elliptic or ovate, obtuse or acutish, serrate or doubly serrate, dark green and glabrous above, glaucous beneath and puberulous on the veins, $1\frac{1}{4}$ - $2\frac{1}{2}$ in. long: fls. about 2 in. across, pale pink, in loose corymbs; pedicel and receptacle copiously glandular-hispid; sepals ovate-lanceolate, long-caudate with foliaceous serrate tips: fr. oblong-ovoid with narrow neck, about 1 in. long, deep red. June. Cent. China. B.M. 8569. J.H.S. 27:486.—This handsome rose has proved fairly hardy at the Arnold Arboretum and is very showy in June with its ample clusters of large pink

fls. and again in fall with the nodding clusters of deep red hips.

45. *macrophylla*, Lindl. Large, upright shrub: flowering branches with few prickles or unarmed: lfts. 9-11, elliptic-ovate to elliptic-oblong, acute, simply serrate, glabrous above, pubescent beneath, 1-2 in. long; stipules glandular-ciliate: fls. 1-3, red, about 2 in. across; pedicels and receptacle glandular-setose or naked; sepals lanceolate, long-caudate, entire: fr. oblong-ovoid, red, 1 - $1\frac{1}{2}$ in. long. Himalayas. W.R. 50. This species is tender and rarely cult. but several of the allied Chinese species when first intro. were distributed as *R. macrophylla* or varieties of *R. macrophylla*, such as *R. Moyesii*, *R. setipoda*, *R. Davidii*, *R. sertata*, *R. persetosa* (see suppl. list for the last three species); to *R. persetosa* belong *R. macrophylla* var.

acicularis, Vilm., and *R. macrophylla* f. *gracilis*, Vilm., while *f. gracilis*, Focke, belongs partly to *R. sertata* and partly to *R. Moyesii*.

46. *Moyesii*, Hemsl. & Wilson (*R. macrophylla* var. *rubro-staminea*, Vilm. *R. Fargesii*, Hort.). Shrub, to 10 ft.: branches with scattered short straight prickles: lfts. 7-13, nearly sessile, ovate or elliptic to ovate-oblong or sometimes nearly orbicular, closely serrulate, glabrous except the slightly pilose midrib beneath, $\frac{1}{4}$ - $1\frac{1}{4}$ in. long; rachis puberulous, glandular and bristly; stipules wide, glandular-ciliate: fls. solitary or 2, deep blood-red, $1\frac{3}{4}$ - $2\frac{1}{2}$ in. across; pedicels short, stipitate-glandular like the receptacle, or the latter glabrous; sepals are ovate, abruptly long-caudate: fruit deep orange-red, oblong-ovoid, narrowed into a neck, 2 - $2\frac{1}{2}$ in. long. June. W. China. B.M. 8338. J.H.S. 27:489. V.F. 95. G. 37:427. Gn. 72, p. 313. J.H. III. 56:587. G.M. 51:478.—A strikingly beautiful rose; its fls. vary considerably in color, from dark blood-red, the color of the typical form, through deep rose to light pink. The extreme light pink form has been distinguished as *f. rosea*, Rehd. & Wilson.

47. *gymnocarpa*, Nutt. Sts. slender, attaining 10 ft., with straight slender prickles and bristles: lfts. 5-9, broadly elliptic to oblong, doubly glandular-serrate, usually glabrous, $\frac{1}{2}$ -1 in. long: fls. solitary on short lateral branchlets, pale pink, about 1 in. across; sepals short: fr. orange-red, globose, small; calyx drops before maturity. June, July. Brit. Col. to Calif., east to Mont. W.R. 71.

48. *Willmottiae*, Hemsl. Densely branched shrub, 5-10 ft., nearly glabrous: branches with slender paired prickles: lvs. crowded, $\frac{3}{4}$ - $1\frac{1}{4}$ in. long; lfts. usually 7, elliptic to ovate or sometimes nearly orbicular, usually rounded at the apex, closely and nearly doubly serrate, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. rose-purple, 1 - $1\frac{1}{4}$ in. across, solitary, short-stalked, on short lateral branchlets; sepals lanceolate, caudate: fr. subglobose, $\frac{1}{8}$ - $\frac{1}{2}$ in. long, bright orange-red; the calyx tardily falling off at maturity. May, June. W. China. B.M. 8186.—Very pretty rose, not to be confused with *R. Willmottiana*, Léveillé, which is *R. longicuspis* (see suppl. list), nor with *R. blanda* var. *Willmottiae*, Baker.

3453. *Rosa acicularis* var. *Bourgeauiana* ($\times\frac{1}{2}$). No. 40.

Section 9. PIMPINELLIFOLIÆ. Few Old-World species.

Upright shrubs, usually low: prickles straight, scattered, usually numerous and mixed with bristles: lfts. very small, usually 9; stipules narrow, with divergent and dilated auricles: fls. solitary, without bracts; sepals entire, erect and persistent.

A. Flowering branches bristly and prickly:

lfts. usually rounded at the base: fls.

pink, white, or yellow: fr. black.....49. *spinosissima*

AA. Flowering branches without bristles:

lfts. usually cuneate at the base: fls.

yellow: fr. scarlet.....50. *Hugonis*

49. *spinosissima*, Linn. (*R. pimpinellifolia*, Linn.). SCOTCH ROSE. Low shrub, with upright recurving or spreading branches, 3-4 ft. high, usually densely beset with slender prickles and bristles: lfts. 5-11, usually 9, orbicular to oblong-ovate, simply or doubly serrate, glabrous, sometimes glandular beneath, $\frac{1}{4}$ - $\frac{3}{4}$ in. long: fls. solitary, but usually very numerous along the sts., pink, white, or yellowish, $1\frac{1}{4}$ -2 in. across; pedicels smooth or glandular-hispid: fr. globular, black. May, June. Eu. W. Asia to China. Gn. 55, p. 425; 60, p. 24; 74, p. 598. W.R. 82.—Very variable. Var. *altatica*, Rehd. (*R. altatica*, Willd. *R. grandiflora*, Lindl.). More vigorous: fls. large, white; pedicels smooth. B.R. 888. Gn. 53:170. A.F. 12:1099. Gng. 5:307. F.E. 18:7. C.L.A. 7:620; 20:20. G. 31:389; 34:501. W.R. 86.

Var. *myriacantha*, Koehne (*R. myriacantha*, DC.). Branches very prickly: lvs. doubly glandular-serrate, very small: fls. small, white, blushed. Red. Ros. (1:6, 7). W.R. 88. Var. *inermis*, Rehd. (var. *mitissima*, Koehne. *R. pimpinellifolia* var. *inermis*, DC. *R. mitissima*, Gmel.). Branches almost unarmed: fls. pink. Red. Ros. (1:6, 6). Var. *hispida*, Koehne (*R. hispida*, Sims. *R. lutescens*, Pursh). Taller: lfts. simply serrate: pedicels smooth: fls. sulfur-yellow, $2\frac{1}{2}$ -3 in. across, rather large. B.M. 1570. Gn. 56:398; 62, p. 17. J.H.S. 27:508. W.R. 87. Var. *luteola*, Andr. (*R. ochroleuca*, Swartz). Similar to the preceding variety: fls. pale yellow, 2 in. across: lfts. 7. G. 28:281. Var. *Andrewsii*, Willmott. A low form with double red fls. W.R. 89. There are also other

varieties with double or semi-double, pink, white (G.W. 7, p. 139), or yellow fls. (Gn. 29:448). Several hybrids are known. *R. hibernica*, Smith, a low shrub with glaucous green foliage and small pale pink fls., is a hybrid with *R. canina*. W.R. 98. *R. reversa*, Walldst. & Kit. (*R. rubella*, Smith), with dark green foliage, red fls. and scarlet, pendulous ovate-oblong frs., is a hybrid with *R. pendulina*.

50. *Hugonis*, Hemsl. Fig. 3455. Shrub, to 6 ft.: branches with rather stout compressed prickles, on the shoots mixed with bristles: lfts. 5-11, oval or obovate, to elliptic-oblong, usually broadly cuneate at the base, finely serrate, glabrous, $\frac{1}{8}$ - $\frac{3}{4}$ in. long: fls. $2\frac{1}{2}$ in. across, yellow, solitary on slender glabrous pedicels; sepals lanceolate: fr. depressed-globose, deep scarlet. May, June; fr. Aug. W. China. B.M. 8004. G. 35:417. G. M. 51:243. Gn. 71, p. 295. W.R. 95.—A very handsome free-flowering rose; hardy.

3455. *Rosa Hugonis*. ($\times\frac{1}{4}$)

Section 10. LUTÆÆ. Four Asiatic species. Upright or somewhat sarmentose shrubs, with scattered, straight or hooked prickles, without bristles: stipules usually narrow, with divergent and dilated auricles: fls. yellow, without bracts; sepals usually pinnate, persistent, upright.

A. Prickles straight: lfts. doubly serrate, dark green.....51. *foetida*

AA. Prickles hooked: lfts. simply serrate, bluish green.....52. *hemisphaerica*

51. *foetida*, Herrm. (*R. lutea*, Mill. *R. Eglanteria*, Linn., not Mill.). AUSTRIAN BRIAR. Shrub with long, slender, often sarmentose or climbing brown sts., becoming 10 ft. high, usually with straight prickles: lfts. 5-9, broadly ovate to oval, doubly glandular-serrate, dark green above, often glandular, $\frac{1}{2}$ -2 in. long; stipules glandular-serrate: fls. sometimes several, but without bracts to the main pedicel, bright yellow, 2- $2\frac{1}{2}$ in. across, of unpleasant odor: fr. globular. June. W. Asia. B.M. 363. Gn. 53:22. W.R. 90. Var. *bicolor*, Willmott (*R. lutea* var. *punicea*, Aschers. & Graebn. *R. punicea*, Mill. *R. bicolor*, Jacq.). COPPER AUSTRIAN BRIAR. Fls. orange-scarlet within. B.M. 1077. Gn. 53, p. 23; 55, p. 425. W.R. 91. Var. *persiana*, Rehd. (*R. lutea* var. *persiana*, Lem. *R. lutea* var. *plena*, Hort.), PERSIAN YELLOW, is a double-fl. form; it is more double and more free-flowering than the Sulphur Rose. F.S. 4:374. Var. *Harrisonii*, Hort., HARRISON'S YELLOW ROSE, is of paler color and a little less double than Persian Yellow, but it blooms more freely, is more vigorous, hardier and easier to grow. It is of American origin and may be a hybrid of the Austrian Briar rose with *R. spinosissima*. F.E. 18:6.

52. *hemisphaerica*, Herrm. (*R. glaucophylla*, Ehrh. *R. sulphurea*, Ait. *R. Rapinii*, Boiss. & Bal.). SULPHUR ROSE. Closely allied to the preceding: sts. slender, with hooked prickles: lfts. obovate, cuneate at the base, simply serrate, bluish green: fls. usually solitary, double, scentless, light yellow; pedicels glandular-hispid. June. W. Asia. B.R. 46. W.R. 93.

3454. *Rosa acicularis* var. *Engelmannii* ($\times\frac{3}{4}$). No. 40.

Section 11. *SERICEÆ*. Three Asiatic species. Erect shrubs with the prickles in pairs: stipules narrow, with erect dilated auricles: fls. solitary, without bracts; sepals entire, persistent, and upright; petals usually 4; styles somewhat exserted.

A. *Lfts. generally ovate or obovate, 7-11:*

fr. slender-stalked 53. *sericea*

AA. *Lfts. generally oblong, 9-17: fr. on a thickened fleshy stalk ½ in. long* ... 54. *omeiensis*

53. *sericea*, Lindl. (*R. tetrapétala*, Royle). Attaining 12 ft., with prickly and often bristly branches: lfts. 7-11, oval or obovate, serrate, glandular or silky pubescent beneath, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. white, $1\frac{1}{2}$ -2 in. across; petals usually 4, rarely 5; fr. globose or turbinate. May, June. Himalayas. B.M. 5200. R.H. 1897, pp. 444, 445. J.H. III. 43:7. W.R. 52.

3456. *Rosa omeiensis*. ($\times \frac{5}{6}$)

54. *omeiensis*, Rolfe. Fig. 3456. Shrub, to 10 ft.: the young shoots densely bristly: lfts. 9-17, oblong or elliptic-oblong, acutish, cuneate at the base, serrate, glabrous, $\frac{1}{3}$ - $\frac{3}{4}$ in. long: fls. white, over 1 in. across; petals usually 4; fr. ellipsoid, $\frac{1}{3}$ - $\frac{1}{2}$ in. long, red, borne on a yellow or red thickened stalk of about equal length. May, June: fr. in July, Aug. W. China. B.M. 8471. —A graceful shrub with handsome

fern-like foliage, early white fls. and especially attractive in summer on account of the contrasting color of the red fr. and its yellow or red fleshy stalk, a feature which distinguishes it at once from any other cult. rose. Has proved hardy in Mass., while *R. sericea* is tender. Var. *pteracantha*, Rehd. & Wilson (*R. sericea* var. *pteracantha*, Franch.). Prickles much enlarged at the base, decurrent and often confluent, forming wide wings, red and translucent on the young shoots. B.M. 8218. G.C. III. 38:260, 261. Gn. 69:300. J.H.S. 27:491. —The large wing-like prickles, which are red and translucent while young, make this rose a conspicuous and striking object.

Section 12. *MINUTIFOLIÆ*. Three American species. Low shrubs with slender, scattered prickles: lfts. small, incised-serrate: stipules with dilated and divergent auricles: fls. solitary, without bracts; sepals erect, persistent, the outer ones pinnate: fr. prickly.

A. *Lfts. cuneate-obovate: fls. 1½-3 in. across.*

B. *Branches glabrous: lfts. usually 5* ... 55. *mirifica*

BB. *Branches stellate-pubescent: lfts. usually 3* 56. *stellata*

AA. *Lfts. ovate to oblong: fls. about 1 in. across* 57. *minutifolia*

55. *mirifica*, Greene. Upright shrub, 3-4 ft.: st. green, glabrous, with slender yellowish white prickles and numerous bristles: lfts. usually broadly cuneate-obovate, incisely or crenately dentate, the teeth sometimes glandular-serrulate, slightly pubescent on both sides or nearly glabrous, light green, $\frac{1}{3}$ - $\frac{3}{4}$ in. long: fls. solitary, deep rose-purple, $1\frac{1}{2}$ -3 in. across: fr. irregularly and broadly turbinate, wrinkled, dull red, prickly

$\frac{1}{2}$ - $\frac{3}{4}$ in. across. April, May. New Mex., White and Sacramento Mts.—This is one of the most beautiful and the most strikingly distinct of the American roses. The fact that it flowers in its native habitat, according to the writer's observation on the Sacramento Mts., New Mex., freely a second time in Aug. indicates a horticulturally valuable trait. Not hardy N.

56. *stellata*, Wooton. Upright shrub to 2 ft.: sts. with whitish prickles, densely stellate-pubescent while young: lfts. usually 3, broadly cuneate-obovate, incisely dentate, pubescent on both sides, somewhat rough above, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. solitary, deep rose-purple, $1\frac{3}{4}$ -2½ in. across: fr. turbinate, prickly. April, May. New Mex., Organ and San Andreas Mts. J.H.S. 27:457. W.R. 103.—Not hardy N.

57. *minutifolia*, Engelm. Fig. 3457. Dense shrub, to 4 ft. high: branchlets pubescent with slender brown prickles: lfts. 5-7, ovate to oblong, incisely dentate, pubescent, $\frac{1}{6}$ - $\frac{1}{2}$ in. long: fls. short-pedicel, pink or white, about 1 in. across: fr. subglobose, hispid. April, May. Calif. G.F. 1:102 (adapted in Fig. 3457). J.H.S. 27:456.—Tender.

Section 13. *BRACTEATÆ*. Two Asiatic species. Shrubs with erect or sarmentose and tomentose or pubescent sts.; prickles in pairs: stipules slightly adnate and pectinate: infl. with large bracts; sepals reflexed after flowering, entire; receptacle tomentose.

58. *bracteata*, Wendl. (*R. Macartnea*, Dum.). MACARTNEY ROSE. Sts. usually procumbent or sarmentose, villous-tomentose, with stout hooked prickles: lfts. 5-9, oval to obovate, crenately serrulate, bright green above and somewhat shining, almost glabrous beneath, $\frac{1}{2}$ -2 in. long: fls. 1 or few, short-stalked, white, 2-2½ in. across; sepals and receptacle densely tomentose. June-Oct. S. China, Formosa; naturalized in Fla. and La. B.M. 1377. B.B. (ed. 2) 2:268. Gn. 70, p. 192.—Handsome half-evergreen climber, not hardy N. There is a double-fl. form.

Section 14. *LEVIGATÆ*. One Asiatic species. Climbing shrub, with scattered hooked prickles: lfts. generally 3; stipules almost free: fls. solitary, without bracts, large, white; sepals erect, entire, persistent.

59. *laevigata*, Michx. (*R. sinica*, Murr. *R. cherokeeensis*, Donn. *R. ternata*, Poir. *R. nivea*, DC. *R. Camellia*, Hort.). CHEROKEE ROSE. Figs. 3458, 3459. High climbing shrub, with slender green prickly branches: lfts. 3, rarely 5, elliptic-ovate to ovate-lanceolate, sharply serrate, shining and glabrous, $1\frac{1}{2}$ -2½ in. long: fls. solitary, white, rarely rose, $2\frac{1}{2}$ -3½ in. across, fragrant; pedicels and receptacle densely bristly: fr. large, obovate, bristly. June. China, Formosa, Japan; naturalized in the southern states. B.M. 2847. B.R. 1922. G.C. III. 6:497. Gn. 53, p. 207; 60, p. 29; 64, p. 95; 68, p. 206; 71, p. 225. F.S.R. 1:294. G. 34:447. M.D.G. 1906:397.—Handsome climbing rose, but not hardy N. A hybrid with *R.*

3457. *Rosa minutifolia*. ($\times \frac{5}{6}$)

Banksia is *R. Fortuneana* (see No. 16). A hybrid with a Tea rose is the ANEMONE ROSE, with large single light pink fls. M.D.G. 1896:345. R.H. 1901:548. Gn. 62, p. 413. G.M. 43:525. W.R. 41.

Section 15. MICROPHYLLÆ. One Asiatic species. Upright spreading shrub, with the straight prickles in pairs: lfts. 7-15; stipules very narrow, with subulate divergent auricles: fls. usually several, with small and quickly caducous bracts; sepals broad, erect and persistent, the outer ones pinnate; carpels only at the bottom of receptacle.

60. *Rôxburghii*, Tratt. (*R. microphylla*, Roxbg., not Desf.). Much-branched spreading shrub 6 ft. high, with straight or ascending prickles: lfts. 7-15, elliptic to oblong-elliptic, acute, sharply serrate, glabrous beneath: fls. pale pink, often solitary, 2-2½ in. across, short-pedicelled; sepals and receptacle prickly: fr. depressed-globose, 1½-2 in. across, very prickly. June, July. China. Var. *plena*, Hort. With double fls. B.M. 3490. B.R. 919. W.R. 44. Not quite hardy N. Var. *normalis*, Rehd. & Wilson, is the wild form with single fls. Var. *hirtula*, Rehd. & Wilson (*R. microphylla* var. *hirtula*, Regel). Lfts. elliptic or ovate-oblong, usually acute, pubescent beneath, ½-1 in. long. Japan. B.M. 6548. For a hybrid with *R. rugosa*, see the latter species.

(The figure following the name indicates the section to which the species belongs.) *R. agræstis* Savi (*R. sepium*, Thuill.) (6). Allied to *R. rubiginosa*. Without bristles; pedicels smooth: fls. small, pale pink or whitish. Eu., N. Afr. W.R. 147.—*R. Alberti*, Regel (8). Allied to *R. Willmottii*. Branches slender, recurving: lfts. 5-9, ovate, pubescent beneath, ¼-1½ in. long: fls. white, 1½ in. across; sepals deciduous; pedicels smooth. Songaria, Turkestan.—*R. amoyensis*, Hance=*R. microcarpa*.—*R. anemoniflora*, Fort. (1). Half-evergreen climbing shrub: lfts. 3-5, ovate-lanceolate, dark green, glabrous and shining: fls. few, white or slightly pinkish, double, the inner petals narrower and smaller. China. Half-hardy. R.H. 1849:281. W.R. 21.—*R. anserinaefolia*, Boiss., is a variety of *R. Beggeriana*, with silky pubescent lfts.—*R. Aschersoniæna*, Graebn. (*R. blanda* × *R. chinensis*). Shrub, to 6 ft., with slender brown branches: prickles hooked: lfts. 5-7: fls. very numerous, small, bright light purple; styles usually exerted. Garden origin. Gt. 51:1504, 1.—*R. banksiopsis*, Baker (8). Branches brown, with subulate prickles, sometimes in pairs: lfts. 7-9, oblong, glabrous, 1 in. or more long: fls. corymbose, red; receptacle glabrous; sepals entire. W. China. W.R. 2:166.—*R. Beggeriana*, Schrank (8). Dense shrub, to 5 ft.: prickles in pairs: lfts. very small and bluish green: fls. corymbose, white; calyx and apex of fr. falling off, leaving the small, globular fr. with an opening at the top. N. Persia to Altai and Songaria. I.T. 5:122. W.R. 54.—*R. bella*, Rehd. & Wilson (8). Allied to *R. Mayensis*. Shrub, to 8 ft.: lfts. 7-9, elliptic or ovate, acutish, glaucous and glabrous or nearly so beneath, ½-¾ in. long: fls. solitary, 1½-2 in. broad, pink; fr. ovoid, scarlet, ¾ in. long. N. W. China. Var. *pollens*, Rehd. & Wilson. Fls. pale pink.—*R. brüsenis*, Koehne (6). Shrub, to 6 ft.: lfts. 7-11, elliptic, glabrous, 1-1½ in. long: fls. 1-2, pale pink changing to white, 3-4 in. across: fr. brown, ovoid. Kurdistan. M.D. 1910, p. 94.—*R. caudata*, Baker (8). Allied to *R. macrophylla*. Much branched: prickles subulate: lfts. 7-9, oblong, glabrous, but hispid on midrib beneath, 1-2 in. long: fls. red, few; pedicels and receptacle bristly; sepals entire: fr. oblong. W. China. W. 163.—*R. cerasocarpa*, Rolfe=*R. Gentiliana*.—*R. chinophylla*, Thory (13). Closely allied to *R. bracteata*. Branches silky pubescent, prickles straight: lfts. elliptic-lanceolate, tomentose beneath: fls. white. India. B.R. 739. Tender.—*R. collina*, Jacq. (5). Allied to *R. alba*, but fls. rose-colored; sepals shorter. Probably hybrid of *R. gallica* with *R. dumetorum*.—*R. coriifolia*, Fries (6). Allied to *R. canina*. Lfts. pubescent beneath; petioles tomentose: fls. pink, short-pedicelled; bracts large; sepals upright after flowering. Eu., W. Asia. W.R. 129. Very variable. Var. *Froebelii*, Rehd. (*R. canina* var. *Froebelii*,

Christ). Of vigorous growth: lfts. simply or doubly serrate, bluish green: fls. small, white.—*R. corymbulosa*, Rolfe (8). Upright or scandent, to 6 ft.: lfts. 3-5, ovate-oblong, doubly serrate, puberulous beneath, ¾-1½ in. long: fls. ¾-1 in. across, red with white eye, in dense umbel-like corymbs: pedicels and receptacle glandular-bristly: fr. globose. W. China. B.M. 8566.—*R. Davidii*, Crépín (8). Allied to *R. macrophylla*. Shrub, to 10 ft.: sts. with scattered straight prickles: lfts. 7-11, elliptic to ovate-oblong, serrate, pubescent beneath, 1-2½ in. long: fls. corymbose, pink, 1½-2 in. across; styles exerted: pedicels like the oblong receptacle glandular-setose, rarely glabrous: fr. scarlet, oblong-ovoid or ovoid, long-necked, ½-¾ in. long. W. China. Var. *elongata*, Rehd. & Wilson. Lfts. 2-3 in. long: fls. fewer: fr. ¾-1 in. long. W. China.—*R. davurica*, Pall. (8). Allied to *R. cinnamomea*. Prickles straight and slender: stipules narrow: lfts. smaller, doubly serrate: pedicels longer, glandular: fr. ovate. Manchuria, Dahuria, Saghalin.—*R. Eze*, Aitch. (*R. xanthina*, Auth., not Lindl.) (10). Upright shrub, to 4 ft., with brown branches: prickles numerous, stout, straight, wide-based: lfts. 9-11, oval, obtuse, dentate, glabrous, glandular, ¼-½ in. long: fls. pale yellow, solitary, short-stalked, 1-1½ in. across: fr. obovoid, ½-¾ in. long, with reflexed sepals. Turkestan, Afghanistan. B.M. 7666. W.R. 2:94.—*R. elliptica*, Tausch (6). Allied to *R. rubiginosa*: lfts. cuneate-obovate, pubescent beneath: pedicels short, usually not glandular: fls. pinkish or whitish. Eu.—*R. elymatica*, Boiss. & Hausskn. (6). Dwarf shrub, to 3 ft., with prickly zigzag branches: lfts. small, usually 5, glaucous: fls. 1-3, small, pink: fr. globular, small. N. Persia.—*R. Fedtschenkoana*, Regel (8). Sts. arching, with prickles and bristles: lfts. 7-9, oblong, glabrous or pubescent beneath, ¾-1¼ in.

3458. Cherokee rose.—*Rosa laevigata*. Commonly known as *R. sinica* (× ½). No. 59.

long: fls. 1-4, white, 1½-2 in. across; pedicels and receptacles hispid. Turkestan. B.M. 7770. W.R. 49.—*R. ferax*, Bieb. (6). Allied to *R. rubiginosa*. Dwarf: lfts. glandular on both sides: pedicels short, not glandular. S. E. Eu., W. Asia. W.R. 154.—*R. filipes*, Rehd. & Wilson (2). Allied to *R. Brunonii*. Sarmentose shrub, to 15 ft., with few hooked prickles: lfts. usually 5-7, oblong-ovate to lanceolate, acuminate, serrate, nearly glabrous, pale beneath, 1¼-3 in. long: fls. white, fragrant, about 1 in. across, in large, loose corymbs; pedicels filiform, 1-1½ in. long, glandular: fr. globose, ½-¾ in. across, scarlet; sepals deciduous. W. China.—*R. floribunda*, Baker=*R. Gentiliana*.—*R. Freundiana*, Graebn. (*R. moschata alba hybrida*, Hort. *R. gallica* × *R. moschata*). Vigorous shrub, to 6 ft.: branches with prickles and bristles: lfts. usually 5: fls. white, 1½-2 in. across, very fragrant; style often exerted. Garden origin. Gt. 57, p. 471. G. 25:311.—*R. Froebelii*, Hort.=*R. coriifolia* var. *Froebelii*.—*R. Gentiliana*, Léveillé (*R. floribunda*, Baker. *R. cerasocarpa*, Rolfe) (2). Allied to *R. Brunonii*. Sarmentose shrub, to 12 ft., with scattered hooked prickles: lfts. 5, elliptic, abruptly acuminate, serrate, glabrous, glaucous beneath, 1½-2 in. long: fls. corymbose, white, fragrant, 1-1½ in. across; pedicels and receptacles glandular: fr. dark red, globose, ½ in. across, with deciduous sepals. Cent. China.—*R. Giraldii*, Crépín (8). Slender-branched shrub, to 6 ft., with straight slender prickles: lfts. usually 7, suborbicular to obovate or elliptic, acute or obtuse, serrate, pubescent, ¼-¾ in. long: fls. solitary or few, pink, 1 in. across: fr. scarlet, ovoid, ½-¾ in. long. Cent. China. Var. *venulosa*, Rehd. & Wilson. Lfts. reticulate beneath, glabrous above.—*R. Giraldii*, Cat. Hesse, is described as having rosy pink fls. with white eye and oblong scarlet frs. It is possibly a synonym of one of the species related to *R. macrophylla*.—*R. glauca*, Vill. (6). Allied to *R. canina*. Lfts. broadly ovate, bluish green: fls. pink; sepals upright after flowering. Eu.—*R. glomerata*, Rehd. & Wilson (2). Sarmentose shrub, to 20 ft., with few scattered hooked prickles: lfts. usually 5-7, oblong or oblong-ovate, short-acuminate, serrulate, rugose above, reticulate beneath and pubescent on the veins, 1½-4 in. long: fls. white,

fragrant, 1 in. across, in dense corymbs: fr. subglobose, orange-red, about $\frac{1}{2}$ in. across; sepals deciduous. W. China.—*R. glutinosa*, Sibth. & Smith (6). Allied to *R. rubiginosa*. Dwarf, densely prickly: lfts. densely glandular on both sides: fls. small, pink. S. E. Eu. W. Asia. W.R. 150.—*R. gratissima*, Greene (8). Allied to *R. californica*. Lfts. glabrous, bright green and glandular, fragrant, thin. Calif.—*R. hawiana*, Kmet. (6). Allied to *R. pomifera*: flowering shoots usually unarmed: lfts. 5-7, elliptic, pubescent beneath, glabrous above: fls. pink, about 2 in. across: fr. globose, densely bristly. Hungary. W.R. 140.—*R. Heckeliana*, Tratt. (R. Hackeliana, Nym.) (6). Allied to *R. rubiginosa*. Dwarf: lfts. tomentose on both sides: fls. usually solitary, small, pink. S. Eu.—*R. indica*, Linn.—*R. microcarpa*.—*R. inodora*, Fries (R. agrestis var. inodora, Keller) (6). Allied to *R. rubiginosa*: lfts. 5-7, obovate, not glandular above: fls. white or pinkish, 1-1 $\frac{1}{2}$ in. across: fr. ovoid, bright red. Eu. W.R. 151.—*R. involuta*, Roxbg.—*R. clinophylla*.—*R. involuta*, Smith (6). Probably hybrid of *R. spinosissima* and *R. tomentosa*. Lfts. doubly glandular-serrate, tomentose beneath: fls. whitish. W.R. 96.—*R. Jäckii*, Rehd. (R. Kelleri, Baker, not Dalla Torre & Sarnth.) (2). Allied to *R. moschata*: low procumbent shrub, with ascending branches: lfts. 7-9, elliptic or elliptic-oblong, glabrous, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long: fls. in corymbs, white, $\frac{1}{2}$ in. across; sepals ovate, abruptly caudate: fr. ovoid, red, $\frac{1}{4}$ in. long. Korea. Hardy.—*R. Jundzillii*, Bess. (6). Allied to *R. canina* but resembling also *R. gallica*. Upright shrub, with straight spines: lfts. almost glabrous, doubly glandular-serrate, rather large: fls. large, pink; fr. subglobose. Eu., W. Asia. W.R. 149.—*R. Kelleri*, Baker.—*R. Jäckii*.—*R. laza*, Retz. (8). Upright shrub, with hooked prickles in pairs: lfts. 7-9, small, light green: fls. small, white; fr. oblong-ovate, small. Turkestan to Songaria and Altai. W.R. 53.—*R. laza*, Lindl.—*R. lucida*.—*R. laza*, Hort.—*R. coriifolia* var. Froebelii.—*R. Leschenaultii*, Wight & Arn. (R. moschata var. Leschenaultii, Crép.) (2). Similar to *R. Brunonii*, but fls. larger, in few-fld. corymbs; pedicels and receptacle glandular-hispid. India. W.R. 15.—*R. longicuspis*, Bertol. (R. Sinowilsonii, Hemsl. R. Willmottiana, Léveillé. R. lucens, Rolfe). Half-evergreen scandent bush, to 20 ft., with hooked prickles: lfts. usually 7, elliptic-ovate to oblong-lanceolate, acuminate, glabrous, lustrous, 1-3 in. long: fls. corymbose, white, $\frac{1}{2}$ in. across; petals silky outside; pedicels about 1 in. long: fr. ovoid, $\frac{1}{4}$ in. long, scarlet or orange-red. W. China. Himalayas. Tender.—*R. lucens*, Rolfe.—*R. longicuspis*.—*R. Lucia*, Franch. & Roehbr. (2). Allied to *R. Wichuraiana*. Habit more upright: lfts. usually 7, narrower and thinner: fls. smaller, Japan.—*R. Ljellii*, Lindl. Probably hybrid of *R. moschata* and *R. clinophylla*. Climbing: lfts. usually 7, oblong, shining: fls. corymbose, large, white, single or double. Intro. from Nepal.—*R. Macounii*, Greene (8). Allied to *R. Woodsii*: low shrub, with rather stout, deflexed prickles: lfts. 9-11, obovate to obovate-oblong, sharply serrate, except at the cuneate base, pubescent beneath, $\frac{1}{2}$ - $\frac{3}{4}$ in. long; stipules glandless: fls. small, pale pink; fr. depressed-globose. Assiniboia to Wyo.—*R. macrantha*, Desportes (R. canina $\times$ R. gallica). Shrub with uniform hooked prickles: lfts. 5-7, chartaceous, ovate to ovate-oblong, pubescent beneath, 1-1 $\frac{1}{2}$ in. long: fls. few, 3 in. across, light pink. Spontaneous in S. France. W.R. 134.—*R. Marcyana*, Boullu (R. gallica $\times$ R. tomentosa). Low, to 2, rarely to 4 ft., prickly and bristly: lfts. 5-7, broadly oval, pubescent on both sides, 1-2 in. long: fls. long-stalked, pink to light purple, 2 $\frac{1}{2}$ -3 in. across. Spontaneous in S. France. W.R. 112.—*R. Marie-Grabnerae*, Aschers. (R. carolina $\times$ R. virginiana). Shrub, to 5 ft., with slightly recurved prickles: lfts. 7-9, elliptic: fls. few, pink; fr. subglobose: blooms almost all summer and very handsome in fall with orange and red foliage, red frs. and pink fls. Garden origin. Gt. 51:1504, 4.—*R. micrantha*, Smith (6). Allied to *R. rubiginosa*. With hooked prickles, without bristles: lfts. slightly pubescent beneath: fls. pale pink, small; styles slightly exserted, glabrous. Eu., N. Afr. W. Asia.—*R. microcarpa*, Lindl. (R. indica, Linn., partly, not Lindl. R. sorbifera, Focke) (4). Branches slender, with scattered, hooked prickles: lfts. 3-7, elliptic to ovate-lanceolate, glabrous, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long; stipules almost free: fls. corymbose, small, white; fr. small, globose; sepals deciduous. China. G.C. III. 37:227.—*R. microcarpa*, Hort.—*R. multiflora*.—*R. montana*, Chaix (6). Allied to *R. canina*. Of vigorous growth, with strong spines: lfts. broader, tinged reddish: fls. pink; pedicels and receptacle glandular-hispid. S. Eu., N. Afr.—*R. multibracteata*, Hemsl. & Wilson (R. reducta, Baker) (8). Shrub, to 6 ft., with straight paired

prickles: lfts. 7-9, broadly oval, glabrous, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. pink, $\frac{1}{2}$ in. across, corymbose with numerous crowded bracts, sometimes few or solitary; styles exserted: fr. ovoid, $\frac{1}{2}$ - $\frac{1}{2}$ in. long, orange-red; sepals persistent. W. China. W.R. 153 (form with few-fld. infl.).—*R. Murielae*, Rehd. & Wilson (8). Slender-branched shrub, to 8 ft., with bristles and slender prickles: lfts. 9-15, elliptic to elliptic-oblong, rarely oval, acutish, serrate, glabrous, except the pubescent midrib beneath, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. white, about 1 in. across, in 3-7-fld. corymbs; pedicels slender, $\frac{3}{4}$ -1 $\frac{1}{2}$ in. long: fr. ellipsoid, orange-red, $\frac{1}{2}$ - $\frac{3}{4}$ in. long. W. China.—*R. orbicularis*, Baker (8). Sts. slender, with subulate prickles in pairs: lfts. 5-7, orbicular, simply serrate, glabrous, $\frac{1}{2}$ in. long: fls. 1-3, 1 $\frac{1}{2}$ in. across, white. S. W. China.—*R. orientalis*, Dup. (6). Allied to *R. rubiginosa*. Dwarf: prickles slender, subulate: lfts. 5-7, simply serrate, pubescent on both sides: fls. pink, solitary, short-pedicelled. W. Asia.—*R. persetosa*, Rolfe (R. macrophylla var. gracilis and var. acicularis, Vilm.) (8). Upright shrub, with densely bristly st.: lfts. 5-9, elliptic to elliptic-ovate, serrate, puberulous beneath, $\frac{3}{4}$ -2 in. long: fls. deep pink, 1 in. across, in large panicles; sepals entire; pedicels and receptacle glabrous. W. China. J.H.S. 27:487, 488.—*R. phanicia*, Boiss. (2). Allied to *R. moschata*. Lfts. usually 5, obtuse or acute: corymbs usually many-fld., pyramidal: styles glabrous. Asia Minor.—*R. Pratii*, Hemsl. (8). Slender-branched shrub, to 8 ft., with slender prickles and numerous bristles: lfts. 7-15, elliptic, obtusish, serrate, pubescent on the veins beneath, $\frac{1}{2}$ - $\frac{1}{2}$ in. long: fls. 1-3, pink, $\frac{3}{4}$ in. across: fr. subglobose to ovoid, scarlet, $\frac{1}{4}$ - $\frac{1}{2}$ in. long; calyx persistent. W. China.—*R. reducta*, Baker.—*R. multibracteata*.—*R. Rübüs*, Léveillé & Vaniot (2). Scandent bush, to 20 ft., with small hooked prickles: lfts. usually 5, ovate-elliptic to obovate, abruptly acuminate, sharply or coarsely serrate, pubescent beneath, rarely nearly glabrous, 1 $\frac{1}{2}$ -2 $\frac{1}{2}$ in. long: fls. in dense corymbs, white, fragrant, 1-1 $\frac{1}{2}$ in. across; pedicels $\frac{1}{2}$ - $\frac{3}{4}$ in. long, glandular: fr. subglobose, dark scarlet, about $\frac{1}{2}$ in. across. Cent. China.—*R. sancta*, Rich. (5). Low shrub, with unequal scattered hooked prickles: lfts. 5-7, elliptic to ovate-oblong, crenate, rugose, pubescent beneath: fls. few, large, pink, on setose pedicels. Abyssinia. W.R. 113.—*R. saturata*, Baker (8). Shrub, to 8 ft., unarmed or with few small prickles: lfts. usually 7, ovate to ovate-lanceolate, acute or short-acuminate, sharply serrate, pale or somewhat glaucous beneath, pubescent on the veins or sometimes nearly glabrous, 1-2 $\frac{1}{2}$ in. long: fls. solitary, dark red, about 2 in. across; anthers purple: pedicels glabrous, $\frac{3}{4}$ -1 in. long: fr. globose-ovoid, $\frac{3}{4}$ in. long, coral-red; calyx persistent. Cent. China.—*R. Scharneckiana*, Graebn. (R. californica $\times$ R. nitida). Shrub, to 3 ft., with slender, often procumbent and ascending st.; prickles slender, in pairs, below often mixed with bristles: lfts. 7-9, elliptic-oblong to oblong, cuneate: fls. 1-5, rose-purple. Garden origin. Gt. 51:1504, 2.—*R. sepium*, Thuill.—*R. agrestis*.—*R. Seraphinii*, Viv. (6). Shrub, 1-3 ft., with copious, unequal, partly hooked prickles: lfts. 5-7, orbicular-ovate, doubly serrate, glandular beneath, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. solitary, very short-stalked, 1 in. across, pink: fr. globose-ovoid, with reflexed, finally deciduous sepals. Medit. region. W.R. 153.—*R. Seraphinii*, Guss.—*R. sicula*.—*R. serotina*, Rolfe (8). Shrub to 5 ft.: branches glaucous, with straight slender prickles in pairs: lfts. 7-11, oval-oblong to narrow-oblong, serrate, glabrous, $\frac{1}{4}$ - $\frac{3}{4}$ in. long: fls. solitary on short branchlets, rose or rose-purple, 2-2 $\frac{1}{2}$ in. across; sepals caudate, entire. W. China. B.M. 8473. G.C. III. 54:166. W.R. 2:153.—Very handsome graceful rose; has proved hardy at the Arnold Arboretum.—*R. sicula*, Tratt. (R. Seraphinii, Guss., not Viv.) (6). Low, $\frac{1}{2}$ -2 ft., with equal, slender, nearly straight prickles: lfts. 5-9, broadly elliptic to orbicular, glandular beneath, $\frac{1}{4}$ - $\frac{1}{2}$ in. long: fls. solitary, rarely to 4, short-stalked, deep red to whitish, 1-1 $\frac{1}{2}$ in. across: fr. small, globose, with upright sepals. Medit. region. B.M. 7761 and G.W. 8, p. 17 (as R. Seraphinii).—*R. Sinowilsonii*, Hemsl.—*R. longicuspis*.—*R. sonomensis*, Greene (8). Allied to *R. californica*. Low shrub, to 1 ft., with straight prickles: lfts. broadly ovate, doubly glandular-serrate: fls. small, in dense corymbs. Calif.—*R. sorbifera*, Focke.—*R. microcarpa*.—*R. Soulieana*, Crép. (2). Upright spreading shrub, to 12 ft., with scattered hooked prickles: lfts. usually 7, oval to ovate-oblong, acute, finely serrate, glabrous, about 1 in. long: fls. corymbose, white, $\frac{1}{2}$ in. across; sepals ovate: fr. ovoid or subglobose, $\frac{1}{2}$ - $\frac{1}{2}$ in. long, orange-red. W. China. B.M. 8158. W.R. 1:18. G. 77, p. 511.—*R. spithamea*, Wats. (8). Allied to *R. californica*. Sts. usually not over $\frac{1}{2}$ ft. high, sparingly branched: lfts. doubly glandu-

3459. *Rosa laevigata*. Run wild in the South and known as Cherokee rose. No. 59.

lar-serrate: fls. usually solitary. Calif.—*R. stylsea*, Desv. (*R. systyla*, Bastard) (6). Shrub with long arching prickly branches: flts. 5-7, ovate-oblong, pubescent beneath, $\frac{1}{2}$ -2 in. long: fls. few, white or light pink, $1\frac{1}{2}$ -2 in. across; styles connate into an exerted column. W. Eu. Red. Ros. (1:5, 2). W.R. 14.—*R. Sueginsowii*, Koehne (8). Shrub with large compressed prickles: flts. usually 9, ovate to ovate-oblong, doubly serrate, pubescent beneath, $1\frac{1}{2}$ -2 in. long: fls. 1-3, pink, $1\frac{1}{2}$ in. across; sepals nearly entire; pedicels and receptacles glandular-hispid: fr. oblong, 1 in. long. W. China. M.D. 1910, p. 96.—*R. systyla*, Bastard=*R. stylsea*.—*R. tomentosa*, Smith (6). Allied to *R. villosa*. Sts. slender, often arching: prickles often slightly curved: flts. smaller, grayish green: fls. pale rose, on longer pedicels: fr. smaller, with the sepals upright spreading, caducous at maturity. Eu. W.R. 139. Gn. 77, p. 511.—*R. trachyphylla*, Rau=*R. Jundzilli*.—*R. Vörbergii*, Graebn. (*R. foetida* $\times$ *R. spinosissima*). Shrub, to 3 ft.: lvs. similar to those of *R. foetida*: fls. white with a delicate flushing of yellow, 2 in. across, early. Garden origin. Gn. 79, p. 323 (as *R. Vorbergii*).—*R. Webbiana*, Wall. (8). Erect shrub, with prickly sts.: flts. 5-9, very small, orbicular or oblong, usually glabrous: fls. mostly solitary, pink, large: fr. ovoid. Himalayas to Afghanistan and Turkestan. W.R. 76.—*R. Willmotiana*, Léveillé=*R. longicuspis*.—*R. xanthina*, Lindl. (10). Upright shrub, to 10 ft. with brown branches: prickles straight, stout: flts. 7-11, oval or elliptic, obtuse, dentate, pubescent beneath, or sometimes glabrous, not glandular, $\frac{1}{2}$ - $\frac{3}{4}$ in. long: fls. solitary, short-stalked, yellow, double, $1\frac{1}{2}$ in. across. N. China, Korea. Var. *normalis*, Rehd. & Wilson, is the single-fl. wild form.—*R. xanthina*, Auth.=*R. Ecæ*.

ALFRED REHDER.

ROSCHÈRIA (name unexplained) *Palmaceæ*, tribe *Arécææ*. A genus of one species, a palm from the Seychelles, allied to *Hyophorbe*.

Slender, erect, spiny at the nodes: lvs. terminal, long-petioled, at first 2-fid, later unequally pinnatisect; segms. numerous, linear-lanceolate, 2-fid at the apex, the numerous nerves scaly beneath; petiole spineless, somewhat 3-sided, concave above; sheath long, prickly: spadix 2-6 ft. long: peduncle long, slender, compressed; branches slender, rather simple, divaricate: spathes many, entire, narrowed, compressed, naked, the 2 lower ones persistent, the upper deciduous: fls. pale: fr. fusiform, small, black. *Roscheria* is little known in Amer. and may not now be in the trade. Cult in greenhouse with plenty of moisture. Prop. by imported seeds, obtainable only rarely. Of little general horticultural importance, but the plant is likely to be seen in choice amateur collections.

melanochætæ, Wendl. (*Verschaffeltia melanochætæ*, Wendl.). Trunk 15-25 ft. high, 2-3 in. diam., with many aerial roots, and when young with a ring of spines below each lf.-scar: lvs. $4\frac{1}{2}$ -7 ft. long; petiole $1\frac{1}{2}$ -2 $\frac{1}{2}$ ft. long, smooth, with a pale band running from the top of the sheath down the back of the petiole; sheath $1\frac{1}{2}$ -2 $\frac{1}{2}$ ft. long, with a few fine black spines; lf.-blade pale green, 3-5 ft. long, 2-3 ft. broad, entire when young, unequally pinnate; segms. 1-1 $\frac{1}{2}$ ft. long, 2-fid at the apex, clothed beneath with peltate scales. Seychelles. I.H. 18:54.

JARED G. SMITH.

N. TAYLOR.†

ROSCÔEA (named after Wm. Roscoe, 1753-1831). *Zingiberacææ*. Half-hardy perennial herbs often grown in the greenhouse, but also used for border planting.

Roots thick, fleshy, and fascicled: lvs. lanceolate or oblong: infl. in terminal spikes; bracts persistent, 1-fl.; fls. purple, blue, or yellow; calyx long, tubular, slit down one side; corolla-tube slender, lateral segms. spreading, upper broad, cucullate, erect; lateral staminoides oblancoate, petaloid, erect, lip large, cuneate, deflexed, 2-cleft or emarginate; ovary 3-celled: caps. cylindric or clavate.—About 15 species, Himalaya region and China. Monographed by Schumann in Engler's *Pflanzenreich*, hft. 20 (vol. IV:46). *Roscoeas* thrive in light turfy loam and are prop. by division. *R. purpurea* is the species best known in cultivation.

alpina, Royle. About 4-6 in. high: lvs. 3-4 in. long, not fully developed at flowering-time, sessile, oblong-lanceolate: spike sessile, 1-2-fl., calyx-tube green, 1 in. or more long, slit nearly to base; corolla-tube white, 1 in. long; limb dark purple, the upper segm. orbicular; staminoid oblong-spatulate, lip deeply 2-cleft. Himalayas and Burma.

cautleoides, Gagnep; also spelled *cautlioides*. About 9-12 in. high: roots fleshy, almost tuberous, lvs. remind-

ing one of an iris and springing from the base: scapes 6-7-fl.; fls. pale primrose-yellow, borne singly in the axils of sheathing bracts. China. G. 36:669. Gn. 77, p. 275; 78:159.—The roots should be planted 4-5 in. below the surface in sandy loam.

purpurea, Smith. Fig. 3460. About 6-12 in. high: sts. with 5-6 sessile, lanceolate lvs.: fls. few, in a sessile spike; calyx green, $1\frac{1}{2}$ in. long, slit deeply down one side as the fl. expands; corolla-tube rather dilated upward; limb purple, rarely pale lilac or white, upper

3460. *Roscoe purpurea*. ($\times\frac{1}{2}$)

segm. about 1 in., very cucullate, lower lanceolate, decurved; staminoid oblancoate-unguiculate: caps. cylindric. Himalayas, Assam, and Burma. B.M. 4630. B.R. 26:61. L.B.C. 15:1404. G.C. III. 8:191. Gn. 78:159. G.W. 14, p. 370. J.F. 3:230.—A variable species, the hardest of the genus. Var. *sikkiménsis*, Hort. (*R. sikkiménsis*, Hort.), is said to differ from the type in being epiphytic, in its roots and sts., and its more numerous fls. which are a different shade of purple. Himalayas. Gn. 78:159.

F. TRACY HUBBARD.

ROSE (see also *Rosa*). The queen of flowers; woody plants, some of them distinctly shrubby, many forms much developed horticulturally, all grown for the beautiful and mostly fragrant flowers in white, yellow, and shades of red. See also *Rosa*.

It been said that the garden rose does not thrive in North America as it does in Europe; but however true this may have been, it scarcely holds today. The success of the rose in this country is very largely a question of the selection of adaptable varieties. These varieties are mostly the compounds of various types and species. In most garden roses it is now impossible to trace the original species with accuracy. For horticultural purposes, a purely botanical classification is of minor consequence, although, in the main, the leading garden-groups follow old specific lines. For a garden classification that follows botanical lines closely, see Baker in *Gardener's Chronicle*, II. 24, p. 199 (1885). It is essential to success, however, that the intending rose-grower have a clear understanding of the main horticultural groups and the kinds of varieties in them, and this information is provided in Barron's article, beginning on page 3001.

Following are the equivalents of some of the common names of roses:

Ayrshire.....	<i>R. arvensis</i> var. <i>capreolata</i> .
Banks Rose.....	<i>R. Banksia</i> .
Bengal.....	<i>R. chinensis</i> .
Bourbon.....	<i>R. borbonica</i> .
Champney.....	<i>R. Noisettiana</i> .
Cherokee.....	<i>R. laevigata</i> .
Cinnamon.....	<i>R. cinnamomea</i> .
Damask.....	<i>R. damascena</i> .
Dog.....	<i>R. canina</i> .
Eglantine.....	<i>R. rubiginosa</i> .
Macartney.....	<i>R. bracteata</i> .
Memorial.....	<i>R. Wichuraiana</i> .
Moss.....	<i>R. gallica</i> var. <i>muscosa</i> .
Musk.....	<i>R. moschata</i> .
Noisette.....	<i>R. Noisettiana</i> .
Prairie.....	<i>R. setigera</i> .
Provence.....	<i>R. gallica</i> .
Scotch.....	<i>R. spinosissima</i> .
Sweetbrier.....	<i>R. rubiginosa</i> .
Tea.....	<i>R. odorata</i> .

When one speaks of roses, the hearer is likely to think only of the large improved kinds of the gardens; and yet there are more than one hundred well-recognized species-forms of *Rosa*, while only a dozen or so have entered largely into the horticultural forms. The systematic account beginning on page 2981 describes sixty species, and many more are entered in the supplementary list at its conclusion. The results of domestication are marvelous, and yet the real breeding of roses is little more than begun, and it confounds the imagination if one contemplates what may appear when endless new combinations are made with the many species that are yet little modified by man. The beginnings in this endeavor by persons in this country and elsewhere, indicate a rich field for useful experiment.

These other species of *Rosa*, aside from the domesticated forms, are of interest and merit largely for land-

scape planting. Usually we do not think of roses as "shrubby" but rather as "flowers," yet *Rosa rugosa* is a good landscape subject, and the same is true of *R. setigera*, *R. multiflora*, *R. laevigata*, and many other species. The lists and suggestions by Rehder, on page 2982, are valuable in this connection. Some of the native wild roses are most attractive in their natural setting, not alone in flowers but in foliage, color of stems, fruit, and general habit; and if the grounds include a suitable area, these plants may well be transferred in quantity. In half-wild and informal borders, on banks, along streams and the margins of woods, many of the roses are admirable. The usual horticultural roses are of little merit in landscape work, because they do not supply sufficient foliage and they lack strong shrubby characteristics; and this fact has no doubt obscured the merits of the wild single roses as material for planting.

The highly improved roses are essentially flower-garden subjects, and they produce better bloom when grown by themselves in regular areas, plantations or beds, where they may receive tillage and such other treatment and care as are specially adapted to them. The preferable location is in the private parts of the place, at the side or rear, and well removed from tall buildings and overhanging trees. They should be given ample space, good soil, and liberal fertilizing, as one would provide these requisites for strawberries, bush-fruits or tomatoes.

The value of the rose product is particularly difficult to estimate. A census-accounting could assemble figures for the nursery stock, the glass devoted to rose-culture, and the value of roses sold by commercial establishments; but the greatest value of the rose is the unmeasurable satisfaction that it returns in thousands of homes and the ministry that it renders to millions of persons.

The literature of the rose is voluminous. The American book writings on the subject are listed on page 1552, Vol. III. For a list of rose books in all languages, see "Bibliografia de la Rosa," by Vergara, Madrid, 1892.

Rose organizations.

The American Rose Society was organized in New York, March 13, 1899, "to increase the general interest in the cultivation and improve the standard of excellence of the rose for all the people," to organize a system of exhibitions, and otherwise "to foster, stimulate, and increase the production in every possible way of improved varieties of the rose, suitable to our American climate and requirements." The Society is a clearing-house for those interested in roses.

Including at first primarily so-called commercial rose-growers—those who grow roses the year round for cut-flowers—the Society has gradually broadened until a considerable number of interested and capable amateur rose-growers are included. Intensive consideration for the rose is fostered by the exhibitions that the Society either conducts or over parts of which it exercises authoritative supervision. For example, four so-called national flower shows, held in Chicago, New York, Boston, and Philadelphia, have had as a prominent attraction notable displays of roses forced into bloom in the early spring, usually offered in competition for the prizes gathered under the leadership of the Society. Inasmuch as these displays have included many of the better climbers and garden roses, large numbers of persons are thereby brought into contact with these advances in rose-culture.

Rose test-gardens have been established under the supervision of The American Rose Society in several places, including, for example, Hartford (Conn.), Washington, Minneapolis, and at Cornell University, Ithaca, N. Y. In these gardens no less than five plants of certain varieties are grown

3461. American Pillar rose.—One of the Multiflora group. ($\times \frac{1}{4}$)

XCIX. Rose.—White, Bride; pink, Bridesmaid.

under comparable conditions, and committees of the Society make an annual inspection at the time of bloom. The rose test-garden in Hartford, in connection with the well-known and beautiful municipal garden planted in 1904 by Theodore Wirth, has proved a wholesome attraction to the more than 115,000 persons who have annually visited it. The superintendent of the Hartford park system estimates that the area included in the rose-garden attracts visitors at the rate of 85,000 persons a year, thus increasing the use of a park system.

The Society maintains a bureau of registration for new roses, provides a scale of points for judging both blooms and plants, and awards medals and certificates for new roses. Its membership includes three classes—life, active, and associate—the latter relation being open only to amateur rose-growers. In 1916, The American Rose Society began the publication of The American Rose Annual, under the editorship of J. Horace McFarland.

Under the leadership of E. M. Mills, of Syracuse, New York, an organization was formed in that city under the title of the Syracuse Rose Society, for the purpose of stimulating local interest in rose-growing. The ideal proposed by Dr. Mills is noted in the following extract from his article in the 1916 American Rose Annual: "It is far more important that 500 people in a city have rose-gardens with from twenty-five to a few hundred bushes in each of them than that there should be only a few large show gardens." Other societies have been formed in the Pacific Northwest directly to promote rose-growing, and various garden clubs and local societies have affiliated with The American Rose Society under its rules. There are a number of affiliated interests. Any horticultural society in the United States or Canada holding an annual exhibition of roses may affiliate with The American Rose Society, and receive medals for the exhibitors.

The present assembly on the rose, aside from the systematic account of *Rosa*, pages 2981 to 2999, comprises the following articles:

Horticultural classification of roses (Barron)	Page 3001
Propagation of roses (Watson)	3004
Roses for the amateur (Huey, Beal)	3006
Outdoor roses for the mid-continental region (Irish) ..	3010
Roses in California (Braunton)	3012
The cultivation of roses under glass (Pierson)	3014
Rose insects (Crosby and Leonard)	3018
Rose diseases (Massey)	3019

L. H. B.

Horticultural classification of roses.

The garden classification of roses presents considerable difficulty, as the several groups have been so much mixed that the original characteristics of each overlap at nearly all points. This is particularly true of the Perpetuals, of which any close classification is impossible. The difficulties increase as one advances. Certain clear-cut characters may be taken to mark given distinct groups in the summer roses, with which the horticulturist has not busied himself so much. Nearly all of these characters are reproduced in the Perpetuals, and, being blended, give rise to endless confusion; thus the following scheme is merely suggestive and should be studied in comparison with the botanical classification (see page 2983).

American rose-culture, so far as garden varieties are concerned, can hardly be said to have established itself as yet. Our growers are today striving to overcome the short-lived character of the blooms, so as to secure in our gardens something of the rose beauty of Europe. The *Wichuraiana*, *Rugosa*, and *Multiflora* roses, combined with our native species and blended again with the best representatives of the garden-groups already grown, with the admixture of some of the newer species from western China, seem to offer the solution. The

beginning has already been made. The hot sun and trying climatic conditions of our summers are fatal to the full beauties of the roses of France and England. The flower is developed so quickly that it has no opportunity to "build" itself, and once developed it fades as rapidly. What has been accomplished for the other florists' flowers remains yet to be accomplished for the rose, and the American rose of the future must be developed to suit the circumstances in the same way that the American carnation has been produced.

CLASS I. SUMMER-FLOWERING ROSES, BLOOMING MOSTLY ONCE ONLY.

- A. *Large-flowered (double).*
 - B. *Growth branching or pendulous: leaf wrinkled...* 1. *Provence*
Moss
Pompon
Sulphurea
 - BB. *Growth firm and robust: leaf downy.....* 2. *Damask and French*
Hybrid French
Hybrid Provence
Hybrid Bourbon
Hybrid China
 - BBB. *Growth free: leaf whitish above, spineless...* 3. *Alba*
 - AA. *Small-flowered (single and double).*
 - B. *Growth climbing: fls. produced singly.....* 4. *Ayrshire*
 - BB. *Growth short-jointed, generally, except in Alpine and Prairie...* 5. *Briers*
Austrian
Scotch
Sweet
Penzance
Prairie
Alpine
 - BBB. *Growth climbing or rambling: fls. in clusters..* 6. *Multiflora*
Baby Ramblers.
 - BBBB. *Growth free: foliage persistent (more or less), shiny.....* 7. *Evergreen*
Sempervirens
Wichuraiana
Cherokee
Banksian
 - BBBBB. *Growth free: foliage wrinkled.....* 8. *Pompon*

CLASS II. SUMMER- AND AUTUMN-FLOWERING ROSES, BLOOMING MORE OR LESS CONTINUOUSLY.

- A. *Large-flowered.*
 - B. *Foliage very rough.....* 9. *Hybrid Perpetual*
10. *Hybrid Tea*
11. *Moss*
 - BB. *Foliage rough.....* 12. *Bourbon*
13. *Bourbon Perpetual*
 - BBB. *Foliage smooth.....* 14. *China*
Tea
Lawrenceana (Fairy)
 - BBBB. *Foliage smooth, very shiny and vigorous...* 15. *Pernetiana*
 - AA. *Smaller-flowered.*
 - B. *Foliage deciduous.*
 - c. *Habit climbing.....* 16. *Musk*
Noisette
17. *Ayrshire*
18. *Perpetual Multifloras*
Wichuraiana Hybrids
 - cc. *Habit dwarf, bushy...* 19. *Perpetual Briers*
Rugosa
Lucida
Microphylla
Berberidifolia
Scotch
 - BB. *Foliage more or less persistent.....* 20. *Evergreen*
Macartney
Wichuraiana

Garden-group 1. *Provence*. Fragrant: branching or pendulous: fls. generally globular: foliage bold, broad, wrinkled, deeply serrate: prickles uncertain; sometimes fine and straight, sometimes coarse and hooked. Rich soil. Prune closely unless very vigorous. Types are Moss rose, a crested form of the *Provence* (Fig. 3442).

3462. *American Beauty*, one of the most popular roses in America. One of the Hybrid Perpetual class. The picture shows a specimen grown in the open. ($\times \frac{1}{2}$)

Pompon, a dwarf group; cupped flowers. See also No. 8. Sulphurea, an undesirable yellow form of difficult cultivation.

Garden-group 2. *The Damask and French*. Damask roses are fragrant: growth robust; spinous: lvs. light green, downy, coriaceous. Hardy: free-flowering: scent destroyed on drying.

French roses: Fragrant (moderately): more upright and compact in growth than the *Provence*: prickles smaller and fewer: fls. generally flat. Very hardy, growing in any soil; petals bleach in strong sunlight; makes abundance of wood, which should be thinned out; perfume develops in the dried petals.

Hybrid French or Hybrid *Provence*, a less robust group with smoother, short-jointed wood and generally light-colored flowers. Type *Princess Clemantine*. Other subdivisions include hybrids with nearly all of the Perpetual group. *Madame Plantier* is a Hybrid *Noisette*. *Coupe d'Hebe* is a Hybrid *Bourbon*.

Hybrid *China* (*China* $\times$ French and *Provence*, partaking more of those parents). Growth more diffuse than the French rose: foliage smooth, shining, and remains on the bush late in the year; thorns numerous and strong. Vigorous of growth; very hardy, and not generally well adapted to poor soil; requires but little pruning.

Garden-group 3. *Alba*, or white roses. A very distinct group: all light-colored flowers of moderate size: leaf whitish above, deep green below: spineless (some hybrids with other groups are very thorny). of free growth; prune closely. Type, *Felicite Parmentier* and *Maiden's Blush*.

Garden-group 4. *Ayrshire*. Climbing roses; very hardy: slender shoots suitable for trellises and trunks of trees: fls. produced singly. Useful for pot cultivation when trained over a frame; fls. vary from white to deep crimson. Type, *Queen of the Belgians*, *Dundee Rambler*. *Ruga* is a hybrid between this group and one of the Teas; fragrant.

Garden-group 5. *Briers*. Under this heading may be grouped most of the well-defined types of garden roses, mostly small-flowered and which do not readily respond to high cultivation. They are more useful as flowering shrubs in the garden than for cut-flowers. The blooms are generally short-lived.

Austrian or Yellow Briers. Small leaflets: solitary flowers: bark chocolate-brown. Very hardy, but require free air and dry soil; will stand very little pruning, as it produces flowers from the upper ends of the old wood. Types, *Harrison's Yellow*, *Austrian Copper*, and *Persian Yellow*.

Scotch or Spiny. This group is well recognized by its excessive spininess; compact low bushes, flowering abundantly and early: flowers small, double. Multiply by underground suckers; fragrant. One hybrid of this group, *Stanwell*, is a Perpetual.

Sweetbrier. Distinguished by the fragrance of its leaves: the fruits are also decorative: foliage small: flowers light-colored and not of much merit.

Lord Penzance Briers. This is a group of hybrids of *R. rubiginosa* (the Sweetbrier), and the older large-flowered varieties, especially *Bourbon* and *Damask*. The results are hardly distributed in America as yet; a few are to be found in select collections. Generally speaking they may be described as very greatly improved Sweetbriers. *Brenda* is particularly desirable for its fruit.

Prairie rose (*R. setigera*). A native species; promises under cultivation to develop some valuable acquisitions, especially in hybridization with other groups: Type, *Baltimore Belle* (Fig. 3439).

Alpine or Boursault. Native of the Swiss Alps; semi-pendulous, long, flexible, smooth shoots: flowers in large clusters; mostly purple or crimson flowers. Good for pillars; very hardy; especially suitable for shady places; should be well thinned in pruning, but the flowering wood left alone: type *Amadis*. Produced by crossing Teas and *R. alpina*.

Garden-group 6. *Multiflora*. The Multiflora group divides itself naturally into the Multiflora true and Baby Perpetual Ramblers. *R. multiflora*, the parent type, is characteristic of the varieties here, the flowers being produced in large corymbs and continuing over a comparatively long time. These varieties are useful as pillar and trellis roses and respond to high cultivation. In pruning, remove only the old canes, leaving the young new growth to carry flowers next year. The American Pillar rose belongs here (Fig. 3461). This group is particularly well adapted to the wild-garden. The name *Polyantha*, sometimes applied to these roses, should be dropped to avoid confusion. The *Rosa polyantha* of botanists is a synonym of *R. multiflora* (p. 2985), but the *Polyanthas* of horticulturists are hybrids of *R. multiflora* with *R. chinensis* or Hybrid Perpetuals; they are low bushy plants, first described as *Polyantha* varieties by Carrière in *Revue Horticole*, 1884.

Garden-group 7. *Evergreen*. The so-called Evergreen roses hold their foliage until very late in the year and in hybridization appear likely to yield varieties which are practically evergreen.

Sempervirens, useful as pillar roses, producing flowers in corymbs: very hardy: vigorous growth: free bloomer: requires considerable thinning in pruning. Types, *Felicite perpetuelle*.

Wichuraiana (Fig. 3440), most popular of all the rampant roses: very hardy, growing in any soil: this promises to be the basis of a very valuable race of American roses: flowers in the type white. Hybrids have been raised from Hybrid Perpetual and Tea varieties giving large flowers, scented; such are *Gardenia* and *Jersey Beauty*. Many hybridists have worked on this species, and the past few years have thoroughly made good the early promise of remarkable developments.

Cherokee (*Rosa laxigata*) of the southern states can be grown satisfactorily away from its native regions only in a greenhouse. (Figs. 3458, 3459.)

The *Banksian* (*Rosa Banksiae*). Two varieties of this are known, the yellow and the white. Requires greenhouse treatment: evergreen: needs very little pruning, merely shortening the shoots that have bloomed. Yellow variety scentless, white variety possessing the odor of violets: flowers are produced in graceful drooping clusters.

Garden-group 8. *Pompon*. A small-flowered Provence rose. See No. 1.

Garden-group 9. *Hybrid Perpetual*, or *Hybrid Remontant*. A large and comprehensive group of much-mixed origin. The mixture with other groups has become so involved as to render separation practically impossible. The characteristics may be described as stiff, upright growth, sometimes inclined to pendulous: flowers of all types: foliage dull green, wrinkled, not shiny: embracing generally the characteristics of the Provence, Damask, French, and the Chinese groups: flowers large, inclined to flat, generally of dark colors. By far the largest and most comprehensive division. (Figs. 3462, 3463.)

Garden-group 10. *Hybrid Teas* form a section of the Hybrid Perpetual group crossed back on to the Tea-scented China, gradually losing all identity. They differ from the pure Hybrid Perpetuals by having foliage of a deeper green and less wrinkled. Some of the best forcing roses are in this group, which promises the greatest development for American rosarians; Robert Scott is a type of this class and is raised from *Merveille de Lyon*, Hybrid Perpetual, and *Belle Siebrecht*, Hybrid Tea. The *La France* type belongs here. (Fig. 3464.)

Garden-group 11. *Moss*. A perpetual-flowering group of the Provence. See Summer Roses and Fig. 3442.

Garden-group 12. *Bourbon*. Dwarf and compact growth, with rounded, more or less shining leaflets: very floriferous: brilliant colors: good outline: in perfection late in the season: requires close pruning. Type, *Hermosa* (or *Armosa*).

Garden-group 13. *Bourbon Perpetual*. Very floriferous: flowers moderate-sized, well formed, in clusters. Type, *Madame Isaac Pereire*.

Garden-group 14. *China* (*Rosa chinensis*). The China or Monthly rose is characterized by its positively perpetual manner of flower. Its blooms become much darkened in color from the action of the sun's rays: flowers small and irregular in shape. Somewhat tender.

The Tea-scented China or Tea Rose (Fig. 3465), *Rosa odorata*, is an allied species. It has large thick petals, with the characteristic tea scent: flowers generally light-colored, pink and creamy yellow: growth free; the best for forcing. The group has been hybridized with all other sections and the Tea influence is seen throughout the rose family. Some of the varieties are climbing. Type *Bon Silene* and *Homer*.

Lawrenceana. Dwarf forms, requiring the same treatment as the Teas. Commonly known as the Fairy Rose.

Garden-group 15. *Pernetiana*. Crosses of Hybrid Teas and "Austrian" brier. Habit generally like Hybrid Teas but more vigorous, with stout spines and coarse

3463. Paul Neyron rose. A good rose-colored variety of the Hybrid Perpetual type. ($\times \frac{1}{2}$)

shiny foliage. The chief distinction, however, is in the remarkable coloring of the flowers, which is indescribable, but often spoken of as "shrimp," with blendings and shadings of burnished copper. Tendency to shed foliage unless grown on almost pure clay. Some forms, as *Juliet*, show affinity to Austrian in resenting pruning, but later kinds are closer to Tea. Type *Madame Edouard Herriot*.

Garden-group 16. *The Musk*. Very fragrant: rather tender: derived from *Rosa moschata*: flowers of pale color. This group has been much hybridized with others, and its identity is lost as a garden plant in that of its derivatives, especially the *Noisette*. The flower-buds are elongated and the flowers produced in clusters.

Noisette (Fig. 3466). Larger flowered than the true Musk roses, flowering very late: free growth: more hardy. The group bears a certain superficial resemblance to the Teas and requires moderate pruning; will grow in any soil. The subgroup has been largely blended with the Teas and with a loss of hardness. In consequence it has fallen into disuse.

Garden-group 17. *Ayrshire*. Perpetual forms of the Ayrshire. For characters, see Summer Roses.

Garden-group 18. *Perpetual-flowering varieties of the Multiflora group*. The term in gardens is taken to include a large number of small cluster-flowered, climbing roses, and is particularly important in American rose-culture, as the basis of a new section of hybrids with the Teas and (erroneously) including hybrids of *Wichuraiana* and Teas. M. H. Walsh in Mas

sachusetts, M. Horvath in Ohio, and Jackson Dawson in Massachusetts have accomplished important work in this field. Some of Walsh's recent introductions, as Debutante and Sweetheart, not as yet fairly tried, and the Dawson rose, may be classed here. They are valuable as trellis and pillar roses for garden decoration.

3464. La France, a famous Hybrid Tea rose. ($\times \frac{1}{2}$)
This picture was made from the White La France. The original La France is pink.

Garden-group 19. *Perpetual Briers*. Of this group there are about five important types.

Rugosa or Japan rose, a low-growing bush: hardy: useful as a hedge plant, and specially adapted for exposed situations near the seashore (Figs. 3446-3448). Hybrids have been made with other Perpetual groups, especially Teas and H. P.'s. Mme. Georges Bruant is a type. The Rugosa blood is strongly seen in all cases.

Microphylla has minute leaflets; now called *Rosa Roxburghii*.

Berberidifolia has leaves somewhat resembling barberry; now known as *Rosa persica*.

Perpetual Scotch, a perpetual-flowering form of *Rosa spinosissima*, probably a hybrid from the Damask.

Garden-group 20. *Evergreen*. Two types, as follows:

Macartney, slender: sweetly scented and very floriferous throughout the season. Is derived from *R. bracteata*.

Wichuraiana. The Wichuraiana hybrids already referred to under Group 7 may dubiously be included here. They have not yet been sufficiently tested. The perpetual-flowering Ramblers have foliage partaking of Wichuraiana and Tea characteristics.

LEONARD BARRON.

Propagation of roses.

The rose is propagated by seeds, cuttings, grafting or budding, by layers and by divisions. The genus is so large and diversified and the requirements are so

many that the whole art of the propagator is needed to satisfy the claims of the Queen of Flowers.

Seeds.—Roses are grown from seeds not only to obtain new varieties but also because many true species are economically procured in this way, e. g., *R. canina*, *R. multiflora*, *R. ferruginea*, *R. rugosa*, *R. rubiginosa*, and the like. The seeds should be gathered in autumn and at once stratified with moist sand or allowed to ferment in tubs with a little water, and kept in a fairly warm place. When well rotted they can be easily rubbed and washed clean and should be planted at once, either in carefully prepared and well-manured beds out-of-doors or in pans or flats in a cool greenhouse. It is sometimes advised that the hips should first be dried and then rubbed clean, but this method often causes delay in germination, a matter sufficiently troublesome without additional complications; they should always be kept moist. Whether they are planted under glass or in the garden it is difficult to forecast their coming up. It may be within a few weeks, e. g., *R. multiflora* under glass; or at the beginning of the second growing season after planting, e. g., Sweetbrier seed planted out-of-doors in November, 1914, may be expected to germinate in the spring of 1916, while *R. rugosa* sown at the same time may come up the following spring, i. e., in 1915, or, a season intervening, it will appear with the Sweetbrier in 1916. Stratifying or fermenting the seeds tends to secure uniform germination within a reasonable time. It has also been suggested, and many things confirm the idea, that early gathering helps to hasten germination; in other words, do not wait for excessive ripeness, but pick the hips as soon as the seeds harden, some time before the fruit is deep red. Until these matters are better understood, all rose seed sown out-of-doors, either in autumn or spring, should be mulched 2 to 3 inches deep with pine needles or other litter. Frequent examinations should be made in spring and the covering at once removed when the seedlings appear; if they do not appear, let the mulch remain to keep down weeds and retain moisture in the seed-bed. Pans or flats in which seed has been planted should be kept at least eighteen months before discarding, with the soil always moist. Notwithstanding the difficulties of germination, the young seedlings make most satisfactory growth and may generally be transplanted into nursery rows when

3465. Yellow Tea rose, Madame Honore Defresne, useful in the South. ($\times \frac{1}{2}$)

one year old. When two years old they are fit for permanent planting. A winter protection of pine boughs is helpful to the young plants. Some seedling roses are extremely precocious, blooming before they are one year old, e.g., some Hybrid Perpetuals and so-called Polyantha roses. The first flowers of seedling roses do not always indicate their real character: in hybridizing it is well to wait for the second or third season before discarding.

Cuttings.—A common means of propagation, under glass and out-of-doors, is by cuttings. Under glass short cuttings 2 to 3 inches long

can be made in November and December from wood of the current year's growth. They should be firmly planted in sand, in flats or pans (Fig. 3467) and kept in a cool greenhouse. They root in February or March, and can either be potted in thumb-pots or kept on in flats until May or June, when they should be planted out in rich beds; salable plants are obtained in October. This is a good way to strike *R. setigera* and its varieties, Crimson Rambler and its allies, *R. multiflora*, and their various offspring, *R. Wichuraiana* and its hybrids, Madame Plantier and doubtless many others. *Rosa indica*, in all its forms, all tender species, and many Hybrid Perpetual roses, are propagated by cuttings of hardened wood grown under glass. Peter Henderson says the wood is in the best condition when the bud is "just open enough to show color." Blind eyes can also be used, and the smaller wood is better than the strong rampant growth. Plant in sand and in a warm house; bottom heat and a close frame are often used but are not necessary. The cuttings are from 1½ to 2 inches long; single eyes strike readily.—In the open air, cuttings of ripened wood may be planted in spring in V-shaped trenches in carefully prepared and well-manured ground. They make strong plants in autumn. Wood of the season's growth is gathered before severe frost, cut into 6-inch lengths, tied in bundles, and stored through the winter by burying in sand. When planted, one eye only should show above ground. This method is recommended for the hardy varieties named above for propagating from short cuttings under glass, but will not give such a large percentage of rooted plants. It is highly probable that some Moss roses, *R. virginiana*, *R. palustris*, *R. spinosissima*, and the like, roses which sucker, can be propagated by cuttings of root or rootstock, but no systematic attempt has been made in this direction.

Budding and grafting.—These are old and well-established methods of propagation. Budding in foreign nurseries is practised in the open air, in June and July, with us in July or August. A dormant shield-bud is employed. The stock is *R. Manetti*, *R. canina*, or any good briar, or *R. multiflora*; in Holland *R. palustris* is esteemed. In European nurseries, *R. canina* is used

for standard, *R. Manetti* for dwarf stocks. Under glass roses are budded also, with a shield-bud, at any season when the bark slips, using for stock a vigorous variety. About Boston the yellow and white Banksian roses once had high local repute for stock for Tea and other tender kinds.

Grafting roses in the open air in this country is not often employed, but in the South, Hybrid Perpetual and other hardy roses are said to be root-grafted in winter (very much as apple stocks are grafted), tied in bundles, stored in sand, and planted out in early spring, the worked portion being set well below the surface. Root-

grafting is an easy and convenient method of propagation under glass. Jackson Dawson's practice is to use the whip- or splice-graft, but the veneer-graft is also employed, with bits of *R. multiflora* root 2 to 3 inches long for the stock, the cion being somewhat longer but of equal diameter. They are firmly tied with raffia and waxed; made into bunches, they are covered with moist moss in an open frame in a coolhouse and left until united. They are then potted off and grown on until they can be hardened off and planted out in May or June, the point of union being well below the surface. A specimen of Dawson's work is shown in Fig. 3468, the stock being a bit of *R. multiflora* root; its age is about three months.

Rosa multiflora is an excellent stock for garden roses, since it does not sucker; this great advantage, is also obtained by using the root-graft as above described. (See article on roses in *Country Life in America*, March, 1916, by Geo. C. Thomas, Jr.) The commercial florists use Manetti stock planted in thumb-pots.

Cut back to the crown, this is splice-grafted and kept in a warm close frame until united; plants are afterward grown on in pots until large enough to put out in the beds, in which they will flower the following winter. There is some difference of opinion among gardeners as to the respective merits of own-root and grafted plants: just now many of the foremost growers prefer the latter for forcing. It is a perplexing question and could be settled by only a series of exact experiments costing much time and

3466. Marechal Niel rose. One of the most popular of the Noisettes. Color yellow. ($\times \frac{1}{2}$)

3467. Short hardwood cuttings of *Rosa setigera*. A single cutting is shown at the left.

money. It is also quite possible that matters of temperature, soil, moisture, and food are equally important factors.

Layering.—This method is employed only when few plants are required; it is cumbersome and wasteful. Layer in early spring, using wood of the last year's growth when possible; the bark of the buried portion should be abraded.

Division is an easy means of increasing *Rosa virginiana*, *R. nitida*, *R. palustris*, *R. spinosissima*, *Crimson Moss* and many other varieties which sucker. Plant thickly in good soil, allow them to grow from three to four years, then lift and tear apart. It will be found that the increase is large and that plants so obtained are salable after one year's growth in the nursery. The year in the nursery may be omitted with the quicker-growing kinds which are to form new plantations on the same estate.

B. M. WATSON.

Roses for the amateur.

Roses may be successfully grown in any soil that will produce fair crops of grain, vegetables, or grass. Certainly the best results will be secured in the more favorable soils and situations, but everyone who loves a rose and possesses a few feet of ground with plenty of sunshine can have his own rose-garden and find pleasure and health in cultivating the plants.

The soil and the beds.

The ideal soil is a rich deep loam, but a good rose-bed can be made in clay, sand, or gravel at little expense and labor. Even the city resident whose house has been erected on the site of an exhausted brick-yard, at a small expense can secure sufficient good soil from the outskirts and manure from the adjacent stables to make a rose-garden that will grow as good plants and flowers as those of his more favored friends who have acres at their disposal, provided always that the sunlight can reach the beds for at least half the day.

The preparation of the ground is the first step of importance. Roses are injured by wet feet, and if the soil is wet it must be thoroughly drained. This can be accomplished by digging out the bed to a depth of 3 feet and filling in 1 foot with broken stone, bricks,

3469. A good rose bed.

cinders, or anything that will allow a free passage of the water through the soil. If this is not sufficient and the water is not carried away, provision must be made for tile-draining; but, except in very extreme cases, the drainage before mentioned will be found amply sufficient. The composition of the soil should depend on the class of roses to be grown, for the Hybrid Remontants do best in a heavy soil containing clay, while those having Tea blood prefer a lighter, warmer ground.

The beds may be made of any desired shape, but a width of 4 feet will usually be the most satisfactory, as a double row can be planted at intervals of $2\frac{1}{2}$ feet, which will be all that is necessary for the strongest-growing varieties, and the blooms can be gathered from each side without the necessity of trampling on the soil. Space may be economized by planting as in the diagram, Fig. 3469.

The plants will then be 1 foot from the edge and 30 inches apart, and each plant will be fully exposed to light and air and will not interfere with its neighbors.

In preparing a bed on a lawn, the sod and earth should first be entirely removed and placed apart; then the best of the subsoil may be taken out and placed on

the other side of the trench, and, lastly, the portion to be discarded is removed, making in all a depth of at least 2 feet. The bottom or floor is then loosened to the full depth of a pick-head, the good subsoil replaced and mixed with a generous dressing of well-decomposed stable manure; lastly, the surface soil and sod are well broken up and also thoroughly enriched with manure, and the bed is filled to the level of the adjoining surface with enough good soil added to replace the discarded earth. When the bed has settled, the surface should be at least 1 inch below that of the

adjoining sod, in order that all the rainfall may be retained. It is a mistake to make any flower-bed higher than the adjacent surface, as in hot weather the soil dries out and the plants suffer.

If the bed is intended for the hardy Hybrid Perpetual or Remontant class, it should contain a fair proportion of clay well mixed with the soil. A sufficient amount is always present in what is known as a heavy loam. If the soil does not contain this naturally, the material should be added and thoroughly incorporated with the other ingredients. If the bed is intended for Hybrid Teas, Teas, Bourbons, or Noisettes, the soil should be lighter, and, if naturally heavy, should have added to it a proper quantity of sand or leaf-mold, and be thoroughly mixed as before. Roses are rank feeders; therefore be liberal with manure for every class.

The plants and planting.

Garden roses may be secured from the dealers grown in two ways: on their own roots, and budded on the Manetti or similar stock. There is much difference of opinion among growers as to the relative value of the two methods of propagation, and it must be admitted that some of the stronger varieties will do equally well either way; but the opinion of the writer, based upon the experience of more than a quarter of a century, is that all of the less vigorous varieties are far better budded

3468. Grafting of *Crimson Rambler* on *Rosa multiflora*, showing plant three months old. At the right is shown the detail of the splice-graft.

than on their own roots, and some are utterly worthless unless budded, notably, Reine Marie Henriette and Viscountess Folkestone, both charming roses when well grown. The budded plants are mostly grown in Europe, taken up as soon as the wood is ripened in the autumn, and shipped to us in the dormant state in time for planting in the latitude of Philadelphia before the ground is frozen. They are usually received in such excellent condition that rarely one in a hundred of the hardy sorts

fails to make a good growth, and a fair bloom the following season.

With the tender sorts, dormant planting out-of-doors in late autumn is attended with much risk, because of the inability of these plants to endure the rigors of our winters before becoming established. Consequently they need much more protection than the hardy varieties. It is really much better to defer the planting until the early spring, if the

3470. Flower of the Manetti rose, used as a stock.

plants can be safely housed through the winter. After they have become successfully established their safety is assured, and they will repay in vigor and excellence the extra work expended on them. Few amateurs, however, have the conveniences for caring for a number of plants under cover in the winter. Therefore they must take the risk of planting in the autumn or cultivate plants grown on their own roots. (For further discussions of budded and grafted roses, see page 3005.)

For budded roses, holes at least 1 foot deep and 15 inches wide should be made for each plant, the collar or point where the bud was inserted and from which the new growth starts placed 2 inches beneath the surface of the soil, the roots spread out and downward (care being taken that no roots cross each other), and all roots covered with fine soil free from lumps of manure. (Fig. 3471.) Manure should never be placed in actual contact with the roots, but near at hand, where the new feeding roots can easily reach when growth begins. The remaining soil should then be packed in firmly, the surface leveled and covered with about 3 inches of coarse litter and manure, and the long wood cut back to about 18 inches to prevent the plant being whipped and loosened by high winds. This extra wood is left to encourage root-action in the spring and should be cut back to three or four eyes as soon as they can be detected when pushing out. Always cut above and close to a strong outside bud, without injuring it, to develop an open and free head, this admitting light and air. If the uppermost bud is on the inside surface of the shoot, the new growth will be directed inward, dwarfing and hampering the plant and preventing proper development. The deep planting above described is necessary to prevent suckers from being thrown out by the roots, as these will speedily choke and kill the less vigorous wood which we are endeavoring to develop. From the writer's experience, the only objection to budded plants is this danger of suckering from the roots; therefore no one should attempt to cultivate budded roses who cannot distinguish the brier should it appear, or who is too careless to dig down at once and cut the wild shoot clean off at the root, rubbing it smooth to prevent its starting again. A very little experience will enable anyone to distinguish the brier. The canes are covered with minute thorns and bear seven leaflets, instead of the usual five. Should any doubt remain, follow the shoot down through the ground and if it starts below the collar, it is a brier; remove it. These wild shoots

usually appear a few inches outside of the regular growth, rarely inside; consequently there is little difficulty in detecting and removing them.

Roses from pots should be planted as soon as the spring weather has fairly settled and all danger of frost is over, that the plants may be firmly established before the heat of summer. Roses planted late in the season never do well. The holes need be made only a little larger than the pot in which the plant is growing. Choose a cloudy day, or the time just before a rain, or late in the afternoon, and, after making the hole, knock the pot off by inverting the plant and striking the edge sharply on a firm object (the handle of a spade which has been firmly placed in the ground in an upright position will answer well). Press the ball of earth firmly between the hands to loosen the earth without injuring the roots, fill the hole with water, insert the plant a very little deeper than it stood in the pot, fill in with soil and pack the earth around it firmly. Pot-grown plants always require staking if the varieties are of upright growth.

Tea roses make a charming effect, where the climate is too cold to winter them in the open successfully, by planting in a bed 6 feet in width, the rows 1 foot from the edge and 2 feet apart, and the bed of any desired length or any multiple of 3 feet. A sectional frame made from tongued and grooved fence-boards, $2\frac{1}{2}$ feet in height at the back and 2 feet in front, facing east or southeast and fastened together with hooks and eyes or screws, the whole covered with ordinary coldframe sash (6 by 3 feet), will preserve the tender varieties through a severe winter. The sash should be freely opened when the temperature is above 30° F. and air admitted during the day when it is 10° or 15° lower. Always close before sunset and open as soon as the sun shines each morning. Opening the sash to keep the plants cool and prevent growth is just as essential as covering to protect from cold, if abundance of flowers is desired. A few days' neglect in opening the sash when the temperature is above 30° will destroy most of the buds for the coming June, as they will be forced out, and one cold night will kill them. Protect from rains or snows, and do not water. Sufficient moisture reaches the roots from the outside to keep the plants in a healthy condition. Teas may be grown successfully in such a bed for many years, and give hundreds of fine blooms from May until November and remain so vigorous that many of the new shoots will be $\frac{1}{2}$ inch in diameter.

Climbing roses make a very effective background, and if trained on a high wire fence give a beautiful display. The strong-growing varieties should be planted 8 feet apart and will each easily fill a trellis 9 feet high. They also look well trained

3471. A typical dormant rose as it should be planted. A, point where bud was inserted.

on the house porch, but are much more likely to be attacked by insect enemies than when planted in the open. Roses grown on porches are usually attacked by aphides and slugs, the leaves becoming riddled and skeletonized, which only infrequently occurs when they are planted in the open sunny garden. If roses are wanted around porches, the Microphyllæ, white and pink, and the Crimson Rambler can be safely planted, as they are not attacked by the slug; but the blooms do not compare favorably with many other roses of their habit. The other varieties

may also be grown around porches, provided that they can be planted where the drippings from the roof will not fall on them and they are kept free from slugs.

Climbing Teas can be grown successfully in the latitude of Philadelphia only in the case of a few varieties.

3472. Reine Marie Henriette, the finest climbing Tea rose for the latitude of Philadelphia. This shows the vigorous growth, the trellis being 10 feet wide and 9 feet high.

Many of the finer kinds are worthless, in spite of all the protection that can be given them, unless they are covered with glass. Lamarque, Bouquet d'Or, Cloth of Gold, Triomphe de Rennes, Marechal Niel, and Reve d'Or have, in the writer's experience, all perished in the first winter, but Reine Marie Henriette, Gloire de Dijon, William Allen Richardson, and Celine Forestier will do well and yield satisfactory results. Reine Marie Henriette blooms finely and makes a magnificent growth, as may be seen in Fig. 3472. The trellis is 10 feet wide and 9 feet high.

Hybrid Sweetbriers, of the Marquis of Penzance kind, are a valuable addition to rose collections. The foliage is abundant, healthy, vigorous, and fragrant, and the exquisite shading of each variety forms a beautiful contrast with the others. It would be difficult to choose among them, for all are worthy of a place, when there is sufficient space for them to revel. They should have a high trellis and be planted fully 8 feet apart.

Pruning roses.

Of the common garden roses, the flowers are produced on new wood of the season that arises from the canes or the crown, or else, in the case of shrubby species, from old trunks or arms. It should be the aim of the grower to secure strong clean canes for this flower-bearing, and not to have so many of them on each plant as to produce much small weak bloom.

Standard or "tree" roses are sometimes grown, but they require so much care in keeping down suckers and in staking and tying, that they are little known in this

3473. Illustrating the pruning of the rose shown in Fig. 3472.

country. They are grown abroad when a few excellent blooms are desired or where space is limited. These tree roses are top-budded, on strong stocks, to the desired variety. Sometimes an effect approaching the true tree rose is produced by tying up a few very strong canes to a stake, as shown in

Fig. 3474. The usual type

of rose-bush in America, however, of the Hybrid Perpetual class, is shown in Fig. 3475.

Pruning the dwarf-growing Hybrid Perpetuals may be begun late in March and regulated by the quantity or quality of the blooms desired. If the effect of large masses be wanted, four or five canes may be left 3 feet in height and all very old or weak growth entirely removed. This will give a large number of flowers, effective in the mass but small and with short weak stalks scarcely able to support the weight of the heads and not effective as cut-flowers, as this sort of pruning is entirely for outside show. After the bloom is entirely past, the long shoots should be shortened back, that the plant

may make good and vigorous wood for the next season of bloom. But if quality be desired, all weak growth should be removed, every remaining healthy cane retained and cut back to 6 or 8 inches. Always cut just above an outside bud, to make an open head that will admit light and air freely. After the first season's growth, there may be about three canes to be retained, but with good care and cultivation the number will increase yearly, until after fifteen or twenty years there will be at least as many canes to be utilized as the plants are years old. The writer had a bed over twenty years from planting, in which each plant, after close pruning, measured 15 to 18 inches in diameter, each cane throwing up four to six shoots 1 to 2 feet in length and sufficiently vigorous in most varieties to hold up the largest flowers and to give magnificent specimen flowers for cutting. Roses grown in this way do not need stakes. They are sufficiently strong and vigorous to hold erect any weight they may be called upon to bear; but late in the autumn, before the high gales of November arrive, they should be cut back to about 2 feet to prevent their being whipped by the winds, for this would loosen the plant and break the newly formed feeding-roots. The plant should not be cut back to the point suggested for spring pruning, as in the hot Indian summer the upper eyes will surely be forced out and the promised blooms for the ensuing season destroyed; so in pruning for protection from November blasts, enough wood should be left to avoid all danger of the lower buds being forced out. The upper buds always develop earliest. Some varieties will not produce large flower-stalks under any method of treatment, notably Prince Camille de Rohan, La Rosarie, and Rosieriste Jacobs; but almost all the other kinds do better under this method than any other, if quality is desired.

Pruning dwarf-growing Tea roses is conditioned on the fact

that they will not endure such vigorous cutting back as the Hybrid Perpetuals. All good strong shoots should be retained unless they form a very close head, when it is better to remove a few from the center. The canes should be shortened about one-third of their length, the branches cut back to one or two eyes, and after each period of bloom the longest shoots should be trimmed back sparingly.

Bourbons need even less trimming. Souvenir de Malmaison, Mrs. Paul, and others of this class should have only the weak ends of each shoot removed, and no more wood cut away than is necessary to remove weak and unhealthy parts.

Climbing roses should be pruned sparingly by simply shortening in the too vigorous shoots and cutting the laterals back to two eyes. Tie all to the trellis in a fan shape, dividing the space as evenly as possible. Fig. 3473 shows the same Reine Marie Henriette pruned and trained on trellis. These continue in flower until November, the early bloom in June being the finest.

3474. Rose trained to a few shoots.

Hybrid Teas should be pruned for quality, and the proper time is when the buds are swelling. The amount of wood to leave on the plant varies with the variety. Shortening the shoots to 4 to 8 inches gives fair results. Cut back the weak growers more severely than the vigorous kinds. To provide for good blooms later, leave three good buds in the axils of the leaves at the base of the shoot when removing flowers or withered blossoms (Beal).

Hybrid Sweetbriers require only such pruning as to shorten back the over-vigorous growth and occasionally to remove some of the oldest shoots to prevent crowding.

Tillage.

Just before growth begins in spring, the surplus rough manure should be removed from the beds and all the remaining fine particles forked in. Deep cultivation is not desirable, as the roots are likely to be injured or broken. Three inches in depth is quite sufficient for a bed that has not been trampled on, and this should be performed with a four-tined digging-fork, which is less likely to cause injury to roots than a spade. The beds should then be neatly edged and the surface raked off smooth and even. Frequent stirring of the surface with a sharp rake is all that is necessary afterward, until the buds begin to develop. Then half a gallon of weak liquid manure applied around the roots of each plant just before a shower will be beneficial. The manure-water should be prepared beforehand, and as soon as a good promise of rain appears, all hands should be called into service and every plant given a full ration. One person should dig a shallow trench with a garden trowel around each plant, the next follow and fill with the liquid manure, being careful to avoid besmirching the leaves; afterward the bed may be raked over level and the rain will wash the food to the roots. This feeding may be repeated with benefit every week until the season of bloom is over, after which stimulation should cease and the plants be permitted to perfect the new wood for the next season's growth. Little pruning is necessary with "cut-backs." So much wood has been removed in gathering the blooms that but little more is left than needed to keep the plants vigorous and healthy. There is another advantage from the system of close pruning: all growths are so strong and vigorous that they are better able to resist insects or disease.

The notion that roses exhaust the soil in a few years and require to be changed into new ground is generally accepted, and is true in most cases; but when beds are formed as previously described and budded roses planted, the vigorous feeding roots find sufficient nutriment in their far-reaching growth to support a healthy development of wood and flowers for many years, especially if a generous top-dressing of manure be applied each autumn and liquid manure supplied liberally during the development of the buds. A top-dressing of wood-ashes after the first spring tillage will materially increase the vigor of the wood and flowers.

Varieties.

The following roses are sufficiently hardy for planting, with more or less protection, even in central New York, where all have been tested (Beal):

3475. A well-grown rose-bush.

Hybrid Perpetual.—Alfred Colomb, A. K. Williams, Anna de Diesbach, Baron de Bonstetten, Baroness Rothschild, Captain Christy, Captain Hayward, Clio, Dr. O'Donel Browne, Duke of Edinburgh, Duke of Teck, Frau Karl Druschki, General Jacqueminot, George Arends, Gloire de Chedane Guinoisseau, Gloire Lyonnaise, Hugh Dickson, J. B. Clark, John Hopper, Lady Helen Stewart, Madame Gabriel Luizet, Magna Charta, Margaret Dickson, Marshall P. Wilder, Mrs. John Laing, Mrs. R. G. Sharnan-Crawford, Oscar Cordel, Paul Neyron, Prince Camille de Rohan, Ulrich Brunner.

Hybrid Tea.—Antoine Rivoire, Augustine Guinoisseau, British Queen, Caroline Testout, Chateau de Clos Vougeot, Chrissie Mackellar, Dean Hole, Dorothy Page Roberts, Duchess of Sutherland, Duchess of Westminster, Earl of Warwick, Edith Part, Etoile de France, Francis Scott Key, Frau Lilla Rautenstrauch, Geoffrey Henslow, George Dickson, Grace Molyneux, Gruss an Teplitz, Gustav Grunerwald, Hector MacKenzie, Irish Brightness, Jonkheer J. L. Mook, Kaiserin Augusta Victoria, Killarney, Killarney Queen, Königin Carola, Lady Alice Stanley, Lady Ash-town, La France, Laurent Carle, Lieutenant Chauré, Madame Jules Grolez, Madame Hector Leuillot, Madame Segond Weber, Marquise de Sinety, Mevrouw Dora Van Tets, Monsieur Joseph Hill, Mrs. A. R. Waddell, Mrs. Wakefield Christie-Miller, Old-Gold, Prince de Bulgarie, Queen Mary, Simplicity, Souvenir du President Carnot, Souvenir de Gustave Prat, Sunburst, Viscountess Folkestone, Wellesley, White Killarney, Willowmere.

Pernetiana.—Arthur R. Goodwin, Louise Catherine Breslau, Lyon, Madame Ruau, Rayon d'Or, Soleil d'Or.

Polyantha or *Baby Rambler*.—Bordure, Catherine Zeimet, Cecile Brunner, Clothilde Soupert, Ellen Poulsen, George Elger, Gruss an Aachen, Leonie Lamesch, Louise Walter, Madame Jules Gouchault, Maman Turbat, Marie Brissonet, Marie Pavie, Mignonette, Mosella, Mrs. W. H. Cutbush, Schneekopf, Triumphe Orleansais.

Moss roses.—Blanche Moreau, Comtesse de Murinais, Crested Moss, Crimson Globe, Princess Adelaide.

Hybrid Sweetbriers.—Amy Robsart, Anne of Geierstein, Brenda, Catherine Seyton, Edith Bellenden, Flora McIvor, Green Mantle, Jeannie Deans, Julie Mannering, Lady Penzance, Lord Penzance, Lucy Ashton, Lucy Bertram, Meg Merrilies, Minna, Rose Bradwardine.

Hardy Yellow roses.—Austrian Copper, Harison's Yellow, Persian Yellow.

Bourbon and Noisette.—Beauty of Rosemawr, Burbank, Caroline Marniesse, Champion of the World, Hermosa, Mrs. Paul, Souvenir de la Malmaison.

Hybrid China and Gallica roses.—Madame Plantier, Rosa Mundi, York and Lancaster.

Rugosa hybrids.—Agnès Emily Carman, Conrad Ferdinand Meyer, Madame Georges Bruant, Madame Lucien Villemot, Nova Zembla, Perfection l'Hay, Blanc Double de Coubert.

Climbing roses, large-flowered types.—Baltimore Belle, Christine Wright, Climbing American Beauty, Countess M. H. Chotek, Dr. W. Van Fleet, May Queen, Prairie Queen, Ruby Queen, Tausendschön, W. C. Egan.

Climbing roses, many-flowered types.—Count Zeppelin, Crimson Rambler, Dawson, Dorothy Perkins, Excelsa, Gardénia, Goldenfinch, Lady Gay, Lady Godiva, Minnehaha, Mrs. F. W. Flight, Mrs. M. H. Walsh, Rene Andre, Rubin, Source d'Or, Thalia, Trier, Wartburg, White Dorothy.

Climbing roses, single-flowered types.—American Pillar, Bonnie Belle, Delight, Eisenach, Evangeline, Jersey Beauty, Hiawatha, Leuchstern, Paradise, Pink Roamer, Silver Moon.

Tea-scented roses.—Duchesse de Brabant, Harry Kirk, Helen Gould, Isabella Sprunt, Madame Lambert, Madame Joseph Schwartz, Maman Cochet, Marie Lambert, Mrs. Herbert Hawksworth, Papa Gontier, Princesse de Sagan, Souvenir de Catherine Guillot, William R. Smith, White Maman Cochet.

Climbing Tea and other tender roses.—Birdie Blye, Climbing Testout, Madame Alfred Carriere, Madame Driout, Mrs. Robert Peary, Reine Marie Henriette.

Bengal roses.—Archduke Charles, Douglas, Lucullus, Madame Eugene Marlitt, Maddalena Scalarandis, Queens Scarlet, and Viridiflora.

Single-Hybrid Tea roses.—Iona, Irish Beauty, Irish Brightness, Irish Elegance, Irish Harmony, Irish Modesty, and Simplicity.

3476. Suggestions for a variety record in the notebook. 1 to 6, Her Majesty; 7 to 12, Margaret Dickson; 8 to 15, Gloire Lyonnaise; 16 to 20, White Baroness.

Much of the charm of growing roses is derived from the accurate knowledge of each variety by name. Yet few amateurs ever accomplish this, chiefly because the labels have been lost or misplaced, and not infrequently a plant becomes known to the cultivator by a name belonging to a neighboring specimen whose label has been placed on the wrong plant. To obviate this, a record should be made in a book kept for the purpose,

with a chart for each bed. Fig. 3476. This should be made at once after the plants are set out and before the labels have become detached.

ROBERT HUEY.
A. C. BEAL.†

Outdoor roses for the mid-continental region.

An intercontinental region, of which central Missouri may be considered a typical representative, often presents gardening problems which markedly differ from those in territory adjacent to large bodies of water. The longer season of intense heat combined with extreme low humidity, together with the frequently sudden and extreme fluctuations in temperature, both during winter and summer, so influence vegetation that if the same degree of perfection is to be attained, and competition successfully met, horticultural operations must be strictly orthodox, and confined to fewer varieties than may be grown elsewhere. This appears to be preëminently true in outdoor rose-growing. This crop can be as successfully produced under the varying conditions to which the region is subject, providing well-established rules, practised by expert rose-growers everywhere in planting and cultivation, are strictly followed, and if the right varieties are chosen. The most hopeless situation is the congested city conditions with air contaminated with poisonous gases. Energy and enthusiasm in gardening in such a place are better spent with other plants.

In planning a location and the arrangement for roses, the purposes for which they are to be grown must be considered. A rose-garden separated from other features of the ground is becoming more and more an important part of parks and private estates. Into this area are grouped a general collection, or specimens of all kinds. It should have a sunny position, though the ground-surface may gradually slope in any direction. Other conditions being identical, a gentle northerly slope is preferred. The kinds may be grouped by types, color, and habit of plant, with all specimens of one kind together rather than the different varieties mixed, —the rugosa, briars, and wild roses bunched in masses, and the climbing sorts on a pergola or trellis. The general dwarf kinds are arranged in irregular or geometrical beds, which, for the sake of convenience, should not be more than from 4 to 6 feet in the greatest width, but of any desired length. Rose-beds may also be located on other parts of the grounds. Low, swampy or poorly drained soil should be avoided, and the beds well separated from trees or large masses of other shrubs. Tea and Perpetual roses should not

be grown as single specimens, but always in groups or beds.

Suitable hedges may be made from many varieties of roses: notably rugosa and its hybrids for a broad or thick hedge, Orleans for a dwarf, and Gruss an Teplitz for medium to tall. Hybrid Perpetual sorts may also be used. With the exception of rugosa, it is better to

3478. Russian form of *Rosa rugosa*. ($\times \frac{1}{2}$)

plant in double rows, about 9 inches apart, the plants 18 inches to 2 feet apart, alternating in each row.

Shrubby masses containing roses only or with an admixture of other shrubs may be made by using wild species, sweetbrier, and rugosa. Climbers and trailers are well and largely used on porches, trellises, tree stumps, and to trail on banks, mounds, and the like.

Types and varieties.

While the Tea roses are the most tender of the groups, many of its varieties can be made to succeed by selecting a location most sheltered from extreme cold, and by providing a thorough winter mulch. Without the latter provision it is useless to attempt any varieties of this type. The following are among the best for this region: Etoile de Lyon, yellow; Maman Cochet, silvery rose; Maman Cochet White; Perle des Jardins, yellow; Mme. Francisca Kruger, coppery yellow; William R. Smith, creamy white; Duchesse de Brabant, pink.

As a type, the varieties of the Hybrid Tea group are more hardy and bloom as freely and continuously as the Teas. There are exceptions with some of the varieties. There is considerable variation in the different sorts, the character of some partaking strikingly of the delicate Teas, while others resemble the more vigorous Hybrid Perpetuals. Many kinds display the best qualities of both types, having their long flowering period and beautiful blooms of good substance, preëminent among which are: Gruss an Teplitz, scarlet; Jonkheer J. L. Mock, pink; General MacArthur, scarlet; LaFrance, pink; Kaiserin Augusta Victoria, white; Antoine Rivoire, pale yellow; Mrs. Aaron Ward, yellow; Lady Ashtown, soft rose; My Maryland, salmon-pink; William H. Taft, pink; Helen Gould, carmine-red; William Shean, pink.

The Hybrid Perpetual is a still hardier type in which are to be found varieties producing blossoms that command the highest prices because of their large size, good substance, and long stems. The most noted representative is American Beauty, still largely grown under glass and in many localities out-of-doors, but for the latter purpose not now generally counted on for the degree of success usually attained by other kinds in

3477. *Rosa rugosa*. ($\times \frac{1}{2}$)

this region. The limited season of flower-production, and the unattractive plant-display the remainder of the year, places this group second to the Hybrid Teas in usefulness for outdoor culture, even though little or no winter covering is required with the one, while it is important that some protection be provided for the other in the more northerly section of this region: General Jacqueminot, brilliant scarlet-crimson; Coquette des Alpes, white; Ulrich Brunner, cherry-red; Frau Karl Druschki, snow-white; Victor Verdier, crimson; Paul Neyron, dark rose; Madame Charles Wood, scarlet; Magna Charta, bright pink; Mrs. John Laing, soft pink.

Roses of the dwarf rambler class are as hardy as Hybrid Perpetuals and as continuous as Hybrid Teas. The dwarf compact habit, together with the clustered masses of bloom, gives it a distinction all its own. The class is very showy in the garden, but with rather short stems, and therefore less valuable for cut-flowers. Occasionally the blossoms bleach a little in conditions following alternate rain and warm sunshine, but this fault is more than outdone by the wealth of color produced over most of the period from beginning of blooming to frost: Clotilde Soupert, rosy white; Baby Rambler, crimson; Baby Rambler, pink; Orleans, red; Katherine Zeimet, white.

The varieties and hybrids of *Rosa rugosa* are useful, especially in landscape masses and usually make excellent hedge-rows. (Figs. 3477-3480.) The single-flowered forms produce bright red hips or seed-vessels that remain on the bushes late in the winter. The bright green leaves give these and similar varieties an interesting and pleasing appearance a large part of the season. Good varieties are: *R. rugosa alba*, white; *R. rugosa rosea*, pink; *R. rugosa rubra*, red; Madame Georges Bruant, double white; and others.

Hybrids of the Sweetbrier type are most charming when in bloom, though the flowers are only medium to small in size, and endure for less than a fortnight. It produces conspicuous fruits and fragrant foliage. The plants are a little slow in making their growth, but meet all weather conditions without injury and live to a great age. The plants form a good shrubby mass or border group. Three good varieties are: Lord Penzance, Lady Penzance, Brenda.

Many of the native species of roses are well used for mass planting, similar to the Sweetbriers. There are several American species known to thrive and bear abundant bloom at St. Louis: *R. palustris*, *R. virginiana*, *R. setigera*.

The most valuable climbing roses for this region fall under two types, *R. multiflora* and *R. Wichuraiana*. Isolated examples have been reported of other forms doing equally well, but the above are by far the most common, and the varieties give so wide a range of color as practically to make other forms unnecessary. They grow rapidly in good soil, and when trained to tree-stumps, trellises, walls or the sides of buildings, quickly make a thorough covering. For covering solid walls and sides of buildings it is better to provide lattice-work a few inches from the building to give opportunity for free circulation of air between the wall and the vines. The Wichuraianas are especially adapted for trailing over banks, mounds, and the like. Good varieties are: Crimson Rambler, crimson; Dorothy Perkins, both pink and white.

After several years' experience with Moss roses, the writer has never seen a plantation that was as satisfactory as other types. At St. Louis they were no more hardy than Hybrid Teas and appear to be more subject to mildew than any other roses. The blooms were not superior to other roses and are rarely grown except by persons maintaining collections of old-fashioned flowers, from whom some good reports have been made. They are more valuable here for their associations than for real horticultural merit.

Soils.

Roses take most kindly to a heavy clay loam enriched with well-rotted cow-manure. Such a soil is characteristically abundant in this region. Sand and ground limestone are added to the average clay loam unless it is known that the soil already contains enough of one or more of these ingredients. Except for Tea

3479. *Rosa rugosa* var. Kaiserin. ($\times \frac{1}{2}$)

roses, lighter soils are avoided as much as possible, and even the Teas do better in ground moderately compact.

Great care must be exercised in the preparation of the soil and providing perfect drainage. Ground for a rose-bed should be excavated 2 to 2½ feet deep and the lower 6 inches filled with pieces of rock or broken brick. The bottom should be connected with a drain-tile to carry the surplus water quickly to a lower level. About a foot of cow-manure, preferably rotted, should be spread over the broken rock and brick, and the excavation filled with heavy clay loam of sufficient depth to keep the surface when settled slightly lower than the surrounding level. To most soils in this region some form of lime should be added to neutralize any acidity that may occur. If there is a greater proportion of clay than loam in the soil a little pulverized sheep-manure, dried blood, or other quick-acting chemical fertilizer will provide available plant-food immediately and give the plants a better start.

Planting.

In starting a rose-plantation, the stock may be dormant wood or growing plants in 3- or 4-inch pots. The plants may have been grown from cuttings on their own roots or budded or grafted on other stock. Plants on their own roots are equally good, cheaper to buy, and there is no danger of the stock plants making growth from the roots in place of the desired kind. Most roses in this region are grown on their own roots. Dormant roses may be set out either in fall or spring, using preferably one- or two-year-old plants. Spring is the most common season, but autumn-planting is practised by some and considered equally good, or even better by many successful growers. The plants are set in the ground 2 or 3 inches deeper than they originally grew, and if planted in autumn, earth is drawn up around the stem and the ground mulched with the most convenient material suitable for the pur-

pose,—rotted manure, leaves, straw, pine needles, and the like. All broken roots are removed and the top cut back to three or four buds. Potted plants are started from cuttings taken in August, September, or October, rooted under glass and grown on during fall and winter to a 3- or 4-inch pot, hardened off in a coldframe, and set out when the ground is warm. For Teas and Perpetuals, the potted plants usually give more bloom the first season and are equally good the following years. There is less labor in planting and the potted stock is no more expensive than dormant material. In setting, the plants are removed from the pots with the soil intact, placed a little deeper than the ground-level, and watered. A frequent and serious error is made in setting

to the desired size. In pruning rose-hedges, a special effort should be made to keep the base as full of new growth as possible.

H. C. IRISH.

Roses in California. (Fig. 3481.)

In many localities in California the rose attains a striking and perhaps unique perfection. That this perfection is not general throughout the state is partially owing to adverse conditions, such as great range of temperature during each twenty-four hours, heavy fogs at critical periods, and the like, but as a rule, failure in whole or in part is due to the lack of intelligent treatment. In the present article, the conditions in southern California are specially in mind, but the discussion will apply, in the main, to other parts of the state.

The chief obstacle to successful rose-culture in California is the attempt to produce blooms every day of the year. Although this practice is quite an impossibility with any rose, the evil is still persisted in by ninety-nine in every hundred possessors of a garden. While roses are grown in great profusion in Los Angeles, few, if any, do as well here as in Pasadena, which, although only 9 miles distant, has the advantage of being several hundred feet higher than Los Angeles, and therefore less subject to fog or great range in daily temperature. In some places a certain few roses will produce an astonishingly fine crop of bloom, when but a mile or two distant, with no change of soil and very slight difference in altitude, they will be utterly worthless; while a like number of other varieties will give as good returns as those first mentioned.

Many roses do fairly well everywhere, and among these *Duchesse de Brabant* more nearly produces a continuous crop of blossoms than any other. For this reason it stands in a class by itself and is not considered in the appended list of the best dozen roses for southern California, though every one should grow at least one bush of this variety. Along with the *Duchesse* might well be placed the *Polyantha*, *Mademoiselle Cecile Brunner*, and the climbers *Cherokee*, *Banksia*, *Ophir* (or *Gold of Ophir*), *Beauty of Glazenwood* or *Fortune's Double Yellow*. All these produce most wonderful crops, but none more so than the last mentioned, which in favored regions produces a wealth of flowers simply dazzling to behold. Many well-known Californian writers assert that *Gold of Ophir* and *Beauty of Glazenwood* are one and the same rose, but this is not the case. *Gold of Ophir* was here for many years before the other made its appearance, and some of the original plants are still growing on many of the homesteads of Los Angeles and vicinity.

All the roses named thus far are worthy of a place in any garden. One of the chief causes of failure by the average amateur is the lack of an intelligent knowledge of the plant's first requirement—recurring periods of absolute rest. These necessary resting-periods are best secured by the withholding of the water-supply. Most amateurs, and a larger part of self-styled "gardeners," persist, against all rules of common sense, in planting roses either in the lawn or in mixed borders with other plants. In either case, all but the roses require a constant watering. Having planted in this fashion, the grower has cast away all chances of first-class results. Rose-beds should never be made a feature in landscape gardening, as the plants when dormant and judiciously pruned are unsightly objects at best. The most obscure spot obtainable with the proper exposure is the place to grow flowers. To obtain the best results the rose requires the same amount of rest here that it secures where the winter season leaves the grower no alternative. But the same amount of rest may here be given semi-annually, with equally good and perhaps better results than is possible with one long annual period of inactivity.

3480. A *Rugosa* hybrid.—*Harison's Yellow* × *R. rugosa*. (× 1/2)

the plants too close. They must have plenty of room for light and air. The *Baby Ramblers* should have about 18 inches apart; other dwarf roses about 2 feet; climbers 4 feet. The surface is cultivated a few times, and at the beginning of hot summer weather the ground is given a thorough mulch, preferably of rotted manure. This feature is probably the most important operation in making a success of monthly roses in this region. Cultivation and mulching should be continued each year, and about every fifth season *Tea* and *Perpetual* roses should be lifted and reset after the ground has been thoroughly shaped.

Pruning.

Roses are pruned in the dormant season, mainly in the early spring, and the method varies somewhat with the different types, as well as individual plants within the types. The severity of the preceding winter often governs the amount of pruning, especially with *Teas*. Plants are sometimes frozen to the ground unless winter protection is given, when it is necessary to remove practically all of the top. All dead wood should be removed. As a general rule, uninjured plants of *Teas* should be pruned more severely than others. The stronger the growth the smaller the proportion of wood to be removed. Climbers, *rugosa*, *sweetbrier*, and wild roses need only enough to keep the plants in shape and

Climate is the all-important feature of rose-culture in California, and if that is satisfactory the character of the soil makes little difference. The dry summer air is a serious drawback to the growth of many roses, there being few places where Moss roses thrive, and these must be grown in whole or partial shade. Niphetos and Marechal Niel are good examples of roses requiring partial shade if good results are desired. Many localities cannot grow the two last mentioned, or such as Perle des Jardins, Meteor, Catherine Mermet, Madame Francisca Kruger, Reine Marie Henriette, and many others, on account of mildew. Even among varieties whose buds are immune, it is often impossible to get foliage unaffected. Injudicious watering is more largely to blame for these unfavorable conditions than any other agency. Laurette is a rose which often produces the only perfect flowers to be found among a hundred varieties, and this is particularly the case in places visited by heavy frosts, Laurette remaining unscathed while all others are more or less blasted. The great rose of the eastern United States, American Beauty, is almost a complete failure here and is not worth growing except in a very few well-favored gardens, and even then it is far from being perfect.

Persons in the southern end of the state and inland sections have yet to learn that fine roses may be grown in summer either in light or heavy shade.

Many roses, also, are of little value in California unless budded or grafted. Of this class Marechal Niel is the most striking example. Examples may be found where this rose has thrived unusually on its own roots, but such cases are marked exceptions. Some persons maintain that all roses are best on their own roots, but such opinions are easily refuted by consulting any of our veteran rosarians. The best roses are root-grafted, but of course this procedure is too expensive for the general nurseryman, and the bulk of the local stock is budded on Manetti or Maiden's Blush, though the Dog rose (*Rosa canina*) and even the Banksia are often used. Those roses grown on their own roots are usually propagated from hardwood cuttings, grown out-of-doors, and December is usually the best month, although they have been successfully rooted from October to March, according to the variety.

Rust bothers but little; likewise scale, although in many neglected gardens the bush and climbers alike may be found covered with both the rose-scale and the red scale of the orange. Fuller's rose-beetle is a nuisance only in small areas, but green-aphis is a pest in winter and spring. La France for many years was the leading rose in California and grew well, budded or on its own roots, in almost any locality, but is now rapidly becoming a thing of the past, though it can never be wholly discarded, for it is still, in a few gardens, the queen of the family; its involuntary retirement from our rose-gardens is due entirely to a "die back" (anthracnose), which affects many other plants than the rose, but seems to have a special liking for La France. Thus far no cure has been found.

(1) A list of the best dozen bush roses and the best half-dozen climbing sorts, as agreed upon by many experts within a range of 20 miles of Los Angeles, is as follows:

Bush roses.—Frau Karl Druschki, Kaiserin Augusta Victoria, Madame Abel Chatenay, Heinrich Munch (Pink Druschki), The Lyon, William Shean, Magna Charta, Ulrich Brunner, Edward Mawley, General MacArthur, Lady Hillingdon, Duchess of Wellington.

Climbing sorts.—Climbing Kaiserin Augusta Victoria, Lamarque, Climbing Souv. of Wootton, Francois Crousse, Duchesse de Auerstadt, Reve d'Or. Outside this list are members of widely divergent classes which should find a place in every large garden, such as the Banksias, the three Cherokees, and both the bush and the climbing Cecile Brunner.

(2) Following are lists of a dozen varieties each of the

different recognized standards of color of roses which have proved best adapted to southern California conditions:

White: White La France, Frau Karl Druschki, Ivory, Kaiserin Augusta Victoria, Mabel Morrison, Molly Sharman-Crawford, Niphetos, Perle von Godesburg, The Bride, The Queen, White Killarney, Maman Cochet. *Pink:* Belle Siebrecht, Betty, Clara Watson, Killarney, Madame Abel Chatenay, Madame Leon Pain, Mlle. Cecile Brunner, Paul Neyron, Maman Cochet, Souv. du President Carnot, The Lyon, William Shean. *Red:* Agrippina, American Beauty, Edward Mawley, General Jacqueminot, General MacArthur, Hugh Dickson, J. B. Clark, Jonkheer J. L. Mock,

3481. California rose-bush.

Lady Battersea, Magna Charta, Papa Gontier, Ulrich Brunner. *Yellow:* Duchess of Wellington, Franz Deegen, George C. Waud, Harry Kirk, Lady Hillingdon, Marie Van Houtte, Mrs. Aaron Ward, Mrs. A. R. Waddell, Perle des Jardins, Rayon d'Or, Soleil d'Or, Sunburst.

Climbing roses.—*White:* Devoniensis, Kaiserin Augusta Victoria, White Mamam Cochet, Madame Alfred Carriere, White Banksia, White Cherokee. *Pink:* Belle Siebrecht, Cecile Brunner, Caroline Testout, Dorothy Perkins, Gainsborough, Pink Cherokee, Tausendschön. *Red:* Papa Gontier, Souvenir of Wootton, Crimson Rambler, Francois Crousse, Red Cherokee (Ramona), Reine Marie Henriette, Reine Olga de Wurtemberg. *Yellow:* Beauty of Glazenwood, Celine Forestier, Duchesse de Auerstadt, Marechal Niel, Reve d'Or, William Allen Richardson, Yellow Banksia. *Sunset and Copper:* Mrs. A. R. Waddell, Lady Hillingdon, Duchess of Wellington, Juliet, Sunburst, Mme. Edouard Herriot, Los Angeles.

(3) Following are roses suitable to California as a whole (John Gill): General MacArthur, Madame Caroline Testout, Lady Hillingdon, Juliet, George Dickson, Mrs. Aaron Ward, Radiance, Mad. Abel Chatenay, Miss Kate Moulton, Ulrich Brunner, Ophelia, Mlle. Cecil Brunner, Frau Karl Druschki,

Laurent Carle, Irish Elegance, Lady Pirrie, Miss Cynthia Forde, Sunburst, Betty, My Maryland, White Maman Cochet, Rayon d'Or, George Arends, Mad. Edouard Herriot.

Climbers.—Climbing Testout, Climbing Belle Siebrecht, Climbing Cecile Brunner, Francois Crousse, Gainsborough, Reve d'Or, Climbing Papa Gontier, Climbing White Cochet, Caroline Goodrich, Climbing Sunburst, Madame Alfred Carriere, Duchesse de Auerstadt.

ERNEST BRAUNTON

The cultivation of roses under glass.

The growing of roses for cut-flowers is the largest item in the greenhouse industry of America at the present time, and the total sales amount to many millions of dollars annually. The rose industry is the backbone of the florist business. With the introduction of varieties that are prolific bloomers, roses have reached a selling value which puts them in reach of the purse of the masses of the people, and the demand is unlimited. Exhibitions have been a factor in educating the public to know roses and in bringing about their present popularity.

The industry is widespread and embraces every section of the country. Southern California grows good roses for the markets in the open field and better quality under glass. In the dry central portion of the West where roses were once considered an impossibility, they are now grown with good success. The climate of the eastern part of the United States seems particularly well adapted to roses, and this section has been considered the home of the greenhouse rose industry. However, careful knowledge of climatic conditions and proper treatment will produce good roses in almost any locality which is favored with weather cool enough to allow proper time for maturity of the flowering stems which, if forced into flower by excessive heat, do not, in warm climates, produce the quality of bloom that is obtainable where more time can be given their development by lower temperatures.

Types of rose-houses (Figs. 3482, 3483).

There are two distinct types of greenhouse construction used by the large commercial rose-growers. The single house has the approval of many, while the connected houses, or ridge-and-furrow sections, are favored by others, because of the smaller expense of construction, the lower cost of heating owing to the absence of outside walls, and the ease of superintend-

ence. Advantages of the single house are its better control, more light, and less trouble with snow and ice, the latter being a serious consideration in the maintenance of the connected houses.

The single house is constructed with iron frame and concrete sides and built even span or two-thirds span to the south. Houses strong and permanent, with good ample ventilation and ample light seem to be the essentials of construction. With connected houses, the essential factor in addition to these is to have the gutter at least 12 feet from the ground, which almost entirely overcomes the effect of shade which the gutter casts by diffusing this over a larger area. A heating-pipe beneath the iron gutter to assist in melting snow and ice is a necessity.

The size of houses to be preferred is largely a question of opinion, but there are certain factors which must not be overlooked. The wide house must necessarily be high, and a house that is high is likely to be lacking in humidity, and the plants consequently will suffer. This seems to be the only objection of consequence to the wide single house. From 40 to 60 feet is the normal width and should be satisfactory, and the length is controlled by the capital of the owner or the natural lay of the land. Houses are workable with economy up to 1,000 feet provided, naturally, with crosswalks at least every 300 feet to save steps for employees. The width of connecting houses should be from 36 to 44 feet, and the length as given also applies to these connecting houses.

Beds and benches.

There is but small connection between the bed or bench and the house containing them, except that in planning new construction the approved plan is to have a walk next to the outside walls and, if the proper width house is selected, this can be accomplished without varying the width of walks and beds or benches. As the modern house is relatively high at the plate or eave, either bed or bench may be used at the discretion of the builder. The construction of the bench is simple, the essential point being durability; this is secured by using cypress lumber and double cross-pieces, which enables the builder to put nails back a short distance into the bottom board and prevents the breaking of the bench at the joint, as the bottoms usually decay first at the ends of the boards. Benches not over 24 inches to the bottom from the ground surface are to be preferred, being easier to work, as the larger part of the actual labor is on the plant itself, at least 12 inches above the bench surface and, if the bench is higher, the labor is correspondingly harder. Ample drainage must be provided by leaving cracks between bottom boards from $\frac{1}{4}$ to $\frac{1}{2}$ inch and using 6-inch width boards. The concrete bench for rose-growing is in the experimental stage and has not as yet shown superiority.

The solid bed, so called, is not in reality solid, except as to side walls. Ample drainage of the ground itself is needed, if solid beds are to be built. If the soil is naturally gravelly, the making of solid beds is simple. If the soil is of heavy clay texture, the building of the solid bed necessitates not only under-draining the surface, but the supplying of coarse gravel or ashes through which the water from the soil may escape to the permanent drain-tiles. These drain-tiles should be laid crossways of the house every 100 feet, and the smaller tile running lengthwise under each bed should empty into these larger cross-tiles. Sides of solid beds are best built with concrete which can be made as thin as $2\frac{1}{2}$ inches

3482. Commercial rose-house showing method of staking, wood-bench construction, and connecting houses.

at the top, and the outsides can be made perpendicular. The inside should be on an angle, and a base width of 6 inches with the flare on the inside will give the wall a purchase on the soil under the bed and hold it in place. Solid beds are cheaper of construction, provided the land is naturally well-drained. They are more expensive when much ashes or gravel must be used. There is another type of solid bed made by using plank nailed to posts for siding which is just as good, but not durable. The bed built by laying broken stone, to serve as drainage, and which elevates the bed to a better working level, is a permanent and satisfactory one, but natural conditions as to stone make this impracticable under usual conditions. Results as to roses grown on raised tables or benches and on solid beds vary very little. The raised bench having the heating-pipe beneath it seems to produce better in the winter months. The solid bed having a cooler soil and a greater rooting depth will give a better quality in the summer months. On the yearly average there is small difference in quantity and quality of product, and the question of bed or bench must be settled by the opinion of the owner and the questions of cost and permanence.

Heating.

In close connection with houses and beds is the question of heating. It is a universally recognized fact that steam heat is essential to the growing of good roses. No attempt will be made to explain boilers and the piping of the houses, except to say that sufficient steam-pipes must be supplied to carry normal temperature in the coldest possible weather, that such pipes should be evenly distributed over the area inclosed, and that the heat should not be overhead, but on the level with or below the level at which the plants are set. The use of steam is due to the fact that quick heat in rose-houses is necessary. The change that comes with the dropping of the sun in the fall and winter must be counteracted by a quick steam-service to prevent a chilling of the plants. A pipe or two in all big houses in summer nights prevents the condensation of moisture on the plants and means the difference between success and failure. Hot-water heat is more uniform than steam, but loses because steam can be obtained on much shorter notice. The use of a hot-water system in conjunction with steam is admirable, and in large establishments is to be recommended. The gentle warmth radiating from the hot-water pipes during the day is not detrimental and enables the grower to use more ventilation, which is a distinct benefit.

Soils for roses.

Soils for rose-culture should be of clay body, but have enough of more friable ingredients to pulverize readily. The grower usually chooses land for the building of commercial rose-houses which has on it the character of soil required. Good heavy clay turf is the material from which to form the compost for rose soil. The fiber of the turf as it decays gives the humus required and leaves the soil open, porous, and in good condition for root-action. Winter-preparation is to be preferred, and the freshly prepared compost which is not over six months old is in ideal condition. Piling alternate layers of soil and cow-manure, using two parts of good heavy clay turf to one part of cow-manure, makes an ideal rose soil. Horse-manure may be used with good results, or a mixture of the two, but cow-manure has the preference.

Lowland soil usually has the body and fiber that is needed, and soil which is part of the year under water has been found to be free from eel-worm or nematode,

which attacks the rose roots; this troublesome pest often infests the soil of the uplands. The meadow soil should be plowed into ridges in the fall and hauled on frozen ground to the place where it is to be composted. The thorough freezing of the soil is considered beneficial as it tends to make it more friable. The compost should be worked over when the frost has gotten out, and after settling will be ready to use when needed. A point should be made to lay the soil-compost near the sec-

3483. Rose propagating-house.

tion where needed in order to save labor in handling when filling the houses.

Greenhouse propagation of roses.

Roses are propagated in two ways for greenhouse growing. These two methods will be discussed separately, considering roses on their own roots before taking up grafted roses.

The usual type of wood selected for own-root cuttings is the strong non-flowering growths. These are commonly known as blind-wood cuttings, but experiment has shown that these growths, if stopped or pinched, as the process is called, can be made to flower, which refutes the statement that such growths are blind, and from these growths flowering plants are produced, which shows clearly that the flowering ability is present. Whether varieties run out by constant use of this type of cutting is an open question which only long-continued experiment can answer, but observation has shown that certain varieties, if propagated from this surplus, or so-called blind growths, will tend to reproduce more of that growth in proportion and to lessen the production of strong flowering wood. The problem seems to be to get into the cutting a sufficient number of dormant eyes to provide good strong flowering growth, and the cutting of this type taken to the heel or union of the shoot with the flowering stem will have such dormant eyes and make a stronger, more vigorous, better producing plant than the cutting which consists of the top few eyes from a growth of this character.

The cutting of flowering stems is usually heavier than the blind-wood cutting, and the wood should be hard or mature enough to allow clean cuts to be made without injury to bark or pith. When the bud shows color is the proper stage of development for the propagation of flowering wood. Two or three eyes should be used, making a clean cut just below the eye and removing the lower leaf; trim back the top leaves at least one-half, and the cutting is ready for the propagating-bed. Cuttings should not be stood in water, but kept sprinkled to prevent wilting.

The propagating-bed should have ample drainage, which can be secured by using coarse ashes for the bottom half of the bed. Five-inch side boards with ashes for drainage and above it 2½ inches of good clean sand constitute a workable propagating medium. Rose-cuttings can be rooted with good success in screened soft coal-ashes, if sand is not available, but extra care must be taken to prevent breaking off the roots in taking the cutting from the ashes, when ready for potting. Distance in the propagating-bed depends on the variety. The leaves should not be allowed to overlap and thus invite fungus. With the heating-pipes beneath the bench, and a uniform temperature of 58° to 60° in the sand and 54° to 60° overhead, the cuttings should be rooted and ready to pot in about four weeks. Do not allow the cutting to begin growth in sand, which it will if not potted when the roots have started. Be sure that clean pots are provided, and the 2¼-inch size is ample for the newly rooted cuttings. Pot carefully so that the tender roots are not broken or

bruised and be sure that some soil is between the cutting and the pot. Water carefully and provide shade for the first few days until the cutting has recovered from the check of moving. Make sure that all the soil is thoroughly moistened, but do not over-water it. Light sprinklings are all that will be required until the roots show activity, which can be ascertained by knocking the plant and ball of soil carefully from the pot, taking care not to break the ball of soil. As the plant begins to grow, remove all shade and keep the plant growing. It will require more water with the increase in foliage.

When the plant fills the pot nicely with roots, repot into a larger pot,—the 3-inch size will be ample for its requirements for the next six weeks. Keep the young plants clean and growing, using the same treatment as for plants on the bench for the various insects and fungi. Shift into larger pots, if necessary, but keep them growing.

Grafted roses are very distinct in handling from the own-root plants. It is best to start with strong-rooted Manetti stock, which rose species has been chosen for its strength of growth and the freedom with which the cions unite with it. Manetti is grown from hardwood cuttings taken during the winter months, and which are planted in early spring in the open field. These are kept growing rapidly throughout the summer, are dug in the fall and are ready when potted for grafting. Manetti should be disbudded or suckered, which means the removal, so far as is possible, of all eyes which are below the point at which the graft is to be made. In growing Manetti, deep planting is advisable as the stem which has been under ground all summer, cuts better and makes a better union than the harder stem which has been exposed. Manetti varies very little with the section, but varies with the method of growing and grading. The deep-planted, well-graded Manetti, whether English-, French-, Dutch- or American-grown, is equally valuable and serviceable, but the great variation in the growing and handling has caused the erroneous

opinion that Manetti from certain sections is superior. Labor values alone prevent the American grower from producing his own Manetti, but irrigation is necessary in our climate. Having pencil-size Manetti,—being for best work about the thickness of a lead-pencil,—the process of grafting is simple. A cut is made as close to the pot-level as possible diagonally across the Manetti. The cion is cut on the same slant and is tied to the stock with raffia fiber (Fig. 3484). Raffia is used because it decays and does not need to be cut away as will be necessary with string, and it covers the union more completely. The union of the cambium layer is the essential point, and if the cion is not equal in size to the stock, one should be sure of a perfect union on one side. The rapid flow of sap which occurs when the new grafted plant is put into the case covers the union and growth begins. In a temperature from 76° to 78° the first week and from 70° to 72° the two succeeding weeks, with careful ventilation and shade from hot sun, the union should be perfect and the young plant ready to be taken into the air and light when hardened sufficiently by increasing these gradually. The grafting-case is usually constructed by having sufficient steam-pipes beneath it to maintain the temperature—a miniature greenhouse.

The advantages of grafted roses over those grown on their own roots are: a stronger root-action, a more rapid-growing plant, and a root-system that will be immune to eel-worm or nematode. Experiments conducted by the Illinois Experiment Station have proved that the production from grafted roses is sufficiently larger to warrant the use of grafted plants. There may be a connection between the use of flowering wood for grafting and increased production, as all cions for grafting purposes should be from selected flowering wood. There is also a difference in varieties and a few are superior on their own roots. It has been generally stated that all yellow or yellow-tinted roses are better on their own roots, but results contradict this statement.

The after-care of the grafted plant varies little from the care of own-root plants. One should be sure to remove any Manetti suckers that appear, cutting close to the stock, and mulch once in small pots before shifting into larger, using for this mulch a compost of good rose-soil with a heavy sprinkling of bone-meal added. Repotting will furnish all the feed necessary, but the top mulch will often keep the plant growing and economize room. Grafted plants come into bud and flower early. The blooms should be kept cut off.

General cultivation, diseases and insect pests.

Having good, clean, thrifty, young plants in 3- or 4-inch pots and a compost soil in the benches or beds, one is ready for planting. The correct spacing is about 12 by 18 inches or 14 by 16 inches; there is some difference in varieties, but the average is about as stated. Planting should be deep enough to cover the union by an inch or more with grafted plants and yet away from the bottom of the bench. Plant firmly and water thoroughly. Growth will soon begin. Keep the plants clean from red-spider by thorough and consistent syringing of the under sides of the leaves with water under pressure. Red-spider is an insect which multiplies rapidly when favored by a dry warm atmosphere, and as its sustenance is the foliage of the plant, it must be eradicated.

Stakes should be set and the plants tied to the stake as soon as they have become established and growth has begun. Wires should be run above the bench, tying the stake made of heavy wire to this 3 feet from the soil-level. In tying the stake to the wire use string, and raffia for tying plants to the stake.

The general care of a rose-house consists in keeping the house properly ventilated, heated and watered, in addition to keeping the plants clean from insects and fungi, and the cutting of the flowers. Ventilation should be given more attention than any other of these problems. How properly to ventilate a rose-house is

3484. Grafted rose, seven weeks from the graft.

dependent upon the condition of the plants and the weather. It is the custom to ventilate freely on bright sunny days, and to guard the plants against draughts, which invites mildew. To obtain the maximum amount of growth, it is advisable to allow the temperature to go above the normal 70° day temperature in bright weather, giving ventilation at the same time, but not sufficient materially to lower the house-temperature. Careful ventilation at night in the summer, and the keeping of a certain amount of fire-heat to dispel dampness does away with black-spot, which disease of the foliage is favored by the condensation of dew or moisture on the plants during the night. Just how to check black-spot is the hardest problem of the rose-grower. Increased temperature with some quick-acting fer-

tilizer and allowing the house to run warm on bright days will often check the disease by inducing quick growth and rapid sap-circulation, giving the plant the new foliage to replace that lost. When the black-spot is persistent, pruning back the plant and allowing it to start again with clean foliage may be the only way of eradication. Black-spot occurs on the Hybrid Tea varieties and, as few pure Tea roses are grown, practically all greenhouse varieties are subject to this serious fungus. Spraying with copper solutions will help to a certain extent in checking it. See the special discussion of this and other diseases, page 3019. The question of temperature is dependent upon the variety grown, but the normal is 60° at night, 70° on bright days, 65° on dark days.

Mildew is a fungus which also attacks the foliage, giving it a dusty appearance and curling the leaf. It also appears on the buds, and, if not controlled, will ruin an entire house. It spreads rapidly when once established. Dusting the plants with flowers of sulfur will kill the fungus if applied on bright days, but fumes from the evaporation of the flowers of sulfur on the steam-pipes will eradicate it much more effectively. Mildew is induced by poor ventilation. Plants should be so grown that the foliage, by constant fresh air, is kept hard and mildew-resisting. A draught from a door or broken glass will bring mildew. When the first sign appears, kill the fungus and prevent it from spreading.

The rose-midge (*Neocerata rhodophaga*) is the worst pest which the rose-grower has to combat, but fortunately this insect has been known to exist only in a few localities, and, to a considerable extent, only in the rose-growing section near Chicago. It is microscopic and is recognized first by its effect. The female deposits its eggs beneath the sepals of the flower-bud or between the folded leaves of the leaf-bud. The egg period is two days, and the maggots, as soon as hatched,

begin to attack the buds. The maggots reach maturity in seven days and then drop to the ground where they pupate and the adult fly emerges six weeks later. As the damage to the plant is done by the maggot which eats the petals, the work of the midge does not affect the growth of the plant, but the buds fail to develop, usually dropping off after being attacked by the maggots. Overgrown plants that do not flower are indications of its presence. The seriousness of the pest is apparent and no precaution is too great to prevent the rose-midge from getting a foothold. Buy plants that are grown in sections not affected. Keep the houses absolutely free from rubbish, both outside and under the benches. If the work of the insect is apparent, get rid of plants and soil in the house and grow other crops

for a season, and start afresh, which is the safest and best plan. See the specialist's account by Crosby, on p. 3013.

The rose is subject to the attack of a nematode, or eel-worm, which infests the roots. The use of Manetti for grafting purposes has, to a large extent, relieved the rose-grower of this trouble, for the Manetti root does not suffer from the attack of nematodes; the use of lowland soil is also a safeguard. Sterilization by means of steam will render soil safe and its usefulness is not impaired, but this is, as a rule, unnecessary.

Rose-galls are a bacterial disease which cause growths on the plants, varying in size, and usually brown in color. These appear at the joints or where cuts have been made. Remove these at once and do not cut them open with a knife used for cutting flowers, because the infection can be carried to the other plants in this manner. Cut off the affected branch and burn it.

3485. A forcing Tea rose. ($\times \frac{1}{3}$)

Thrip is an insect which attacks the leaves and petals. It is small and its work usually can be recognized by the white lines on dark-colored flowers, showing where the surface has been eaten. Green-fly is a sucking insect which attacks the new growths. Both can be readily killed by the evaporation of nicotine preparations upon the steam-pipes, this having almost entirely replaced the burning of tobacco-stems.

Feeding the plants is accomplished by top-mulching, or by liquid fertilizer, or by using both. Aside from bone-tankage, few commercial fertilizers are in use, cow-manure, well-rotted, clear or mixed with well-rotted horse-manure, being more generally used. These manures in liquid form may be used to advantage. Feed light and often is the rule when plants are well established.

Watering depends on crop-condition. Water copiously when the plants are coming into bearing. Water less when the crop is being cut, and sparingly after the crop is cut and before the new growth starts.

The question of humidity in the house is a serious one with the wide, large houses, and where the atmosphere lacks moisture the growths will be hard-wooded and the plants will not be prolific. It is safe to say that a house with all cement walks fails to grow good roses for lack of humidity, and the gravel or ash walk will do much toward furnishing the atmosphere the needed moisture.

Varieties.

Varieties to grow depend largely on the market to which the grower caters. There are two types of greenhouse roses: those which are at their best in the warm summer months, and those which are at their best in cooler weather.

The varieties best suited for summer cutting are My Maryland and its sports, Kaiserin Augusta Victoria, Francis Scott Key, and Mrs. Aaron Ward.

For general use, the best varieties are Killarney and its sports, which are numerous, and of which Double White Killarney, Killarney Brilliant, White Killarney, and Killarney Queen are such notable examples that they must be mentioned; Ophelia, Mrs. Aaron Ward, Mrs. George Shawyer, Hoosier Beauty, Hadley, Milady, Richmond, Radiance, Lady Alice Stanley, Jonkheer J. L. Mock, Sunburst, Mrs. Charles Russell, American Beauty, and the Polyantha roses—Cecile Brunner, Perle d'Or, and George Elgar, which are widely used for corsage bouquets and decorative work. Mrs. Aaron Ward, Double White Killarney, Mrs. George Shawyer, Killarney Brilliant, and Ophelia are the best varieties for cutting continuously for the entire year. Of these varieties mentioned, American Beauty, Mrs. George Shawyer, Radiance, Lady Alice Stanley, and Sunburst are better grown upon their own roots, while the balance of the varieties are superior when grafted on manetti. Mrs. W. C. Whitney was formerly grown as a forcing rose.

Cutting the flowers.

Proper care and cutting of the flowers has as much to do with financial success in the rose industry as the proper growing of the plants. Just when flowers are mature enough to be cut is a matter of variety to a considerable extent. Those varieties which do not have many petals should be cut in the bud, while many of the very double varieties, such as Francis Scott Key and Mrs. Charles Russell, should be allowed partly to expand before being taken from the plant. How much wood to leave when cutting the flowers is also a question of variety to a certain degree, but as a rule two good eyes are sufficient. Certain varieties which naturally throw strong flowering growth from the main stems or hard wood can be cut to one eye from good-sized plants. There is a tendency of plants to increase in size and become awkward to handle if much growth is left in cutting, and production from large overgrown plants is as a rule no greater than from plants more closely headed in by carefully cutting the flowers.

It is customary with some growers to "pinch" all flowering shoots when the bud has reached the size of a pea, and this removal of the bud and first leaf causes a new flowering growth and gives a longer stem, as the flower is cut back to the proper place in the older growth. This method of pinching allows the grower to control the time of maturity of the crop very accurately, eight weeks in the early winter months and seven weeks in February and March being the necessary time for the maturity of the new flowering shoot. This varies a few days with the character of the growth when the pinching is done; those shoots nearer maturity will require less time than the softer or more immature growths. There is also a slight difference in varieties as to the time required to mature the shoot and flower. Thus pinching allows the grower to bring in a crop at the holiday season and produce flowers for exhibition use.

The stronger and more vigorous the growth pinched, the better the quality of the resultant flower and by selection of strong heavy flowering growths and by pinching and careful timing, the roses for exhibition purposes are produced.

When flowers are cut they should at once be placed in water and kept at a temperature from 38° to 42° for several hours to harden them. The stems and flowers fill with water and are then in a condition to be graded. The American Rose Society has established a grading standard to which the leading growers adhere in preparing the product for market. Length of stem is the basis, but quality and substance of bud should be in proportion to length of stem, and a poor quality flower on a large stem on the open market will by no means command the price of a good flower on a stem of the same length. In grading, keep the flowers uniform in length of stem and quality.

Marketing cut roses.

There are three methods of marketing cut roses, viz.: retailing direct to the consumer; supplying flower shops direct; and the shipment of the product to the commission stores which supply the large city florists. It is of first importance to have the product reach the consumer fresh, well hardened, and not too open, for the demand for open flowers is limited. Careful packing for the wholesale market necessitates wooden boxes with cross cleats to hold the roses from moving about in the box, which bruises the flowers. Wooden boxes allow the use of ice to keep the flowers in condition for sale. Heavy waxed paper between the layers of flowers in the boxes aids in handling them conveniently. Any precaution taken to insure the product reaching the consumer in perfect condition is a paying investment, for a good product has little value when bruised and in poor condition.

The sale of flowers direct to the consumer by the grower is becoming greater every year, many of the leading florists operating their own ranges of glass and using the product in their own store. The demand from the large cities where this is not possible to any great extent is increasing yearly. Returns from money invested is in fair proportion to the money earned by investments in any well-conducted line of production, but is dependent upon the skill of the grower and the business-like conduct of the enterprise. The risk of handling a perishable product and the property risk also is heavy, owing to wind, hail, snow, and ice. Deterioration is also heavy because of the excessive humidity necessary to good culture. Rose-growing is an industry catering to the demand for a luxury, and the path to profit is often a thorny one.

W. R. PIERSON.

Rose insects.

ROSE APHIS (*Macrosiphum rosæ*).—Greenish or pinkish plant-lice about one-twelfth inch in length that cluster in great numbers on the tender tips and buds, stunting the growth and injuring the bloom; injurious both in the open and on roses grown under glass. The insect hibernates in the egg stage in the North, but in the South breeding continues throughout the winter. The eggs hatch as the buds are bursting. The aphids of the first generation are wingless as are also a large proportion of the succeeding broods, but winged forms are produced from time to time which serve to disseminate the species. The insects multiply with great rapidity, each female being capable of producing thirty to forty-five young in the course of her life. A generation is completed in less than a month.

Treatment.—Spray with nicotine sulfate (containing 40 per cent nicotine), one part in 800 parts of water—about one teaspoonful in two gallons of water. The efficiency of this solution is increased by the addition of a small amount of soap. Good results may be obtained by thorough spraying with whale-oil soap, or any good soap, one pound in eight or ten gallons of water. It is sometimes a good plan to dip the buds and tips of the branches in a dish nearly full of the solution.

SMALL GREEN ROSE APHIS (*Myzus rosarum*).—A green plant-lice much smaller than the preceding; more troublesome in greenhouses than in the open.

Treatment.—Same as for the rose aphis (above).

AMERICAN ROSE SLUG (*Endelomyia rosæ*).—Greenish or yellowish larvæ that skeletonize the upper surface of the leaves. The eggs

C. Rose, American Beauty.

are laid in the tissue of the leaves by a shining black four-winged fly.

BRISTLY ROSE SLUG (*Cladius pectinicornis*).—Yellowish or greenish, more or less bristly larvæ about $\frac{3}{4}$ inch in length that skeletonize the leaves when young but later eat out holes in the leaf, often leaving only the larger veins. In the North there are three generations annually, the cocoons of the summer brood being placed on the leaves or twigs, those of the winter brood on the ground. The eggs of this species are inserted in the petiole of the leaves by the parent fly which very closely resembles the preceding.

COILED ROSE SLUG (*Emphytus cinctus*).—Larvæ about $\frac{3}{4}$ inch in length that feed on the edge of the leaf with the body coiled beneath it. The larva is metallic green spotted with white above, grayish white beneath; head orange; first segment of the thorax blue and the last two gray. Pupation takes place in the pith of a dead twig.

Treatment for rose slugs.—Arsenate of lead, two pounds in fifty gallons of water or one ounce in $1\frac{1}{2}$ gallons is an effective spray, but if applied too freely may leave a whitish deposit on the foliage. Hellebore, one ounce in two or three gallons of water, or used in the dry form diluted with double its weight of powdered plaster or cheap flour, is also effective. Rose slugs may also be killed with the nicotine solution as recommended for the rose aphid.

ROSE LEAF-HOPPER (*Typhlocyba roseæ*).—A small nearly white leaf-hopper, feeding on the under side of the leaves, extracting the juices and causing the leaves to turn yellowish. The insect spends the winter as eggs which are inserted in the bark.

Treatment.—This leaf-hopper may be controlled by thorough spraying of the under side of the leaves with nicotine solution as recommended for the rose aphid.

ROSE LEAF-ROLLER (*Archips rosaceana*).—Black-headed olive-green caterpillars, about $\frac{3}{4}$ inch in length when mature, that roll and web together the leaves on which they feed. They become full grown in about a month and transform to dark brown pupæ within the rolled leaves. In two or three weeks the light brownish moths emerge and deposit their eggs on the leaves. There are two broods annually on roses grown in the open.

Treatment.—Spray the plants with arsenate of lead, two pounds in fifty gallons of water and make the application early in the season. In greenhouses close watch should be kept for the first appearance of the insect and the caterpillars destroyed before they gain a foothold.

ROSE CHAFER (*Macrodactylus subspinosus*).—Long-legged ungainly grayish brown beetles that swarm into the rose-garden, and devour the leaves, petals, and opening buds. The grubs from which these beetles develop feed on the roots of grasses in sandy soil only. In New York the beetles emerge from the ground about the middle of June and disappear in about a month or six weeks.

Treatment.—This is a difficult insect to control because the beetles will avoid feeding on foliage poisoned with an arsenical. They will, however, eat leaves sprayed with arsenate of lead sweetened with molasses. This method, however, cannot be relied upon to protect the plants when the beetles are numerous, for much damage will be done before the poison has had time to take effect. In the case of a few choice plants it is safer to protect them with mosquito-netting during the period when the beetles are most abundant.

ROSE MIDGE (*Neocerata rhodophaga*).—Small whitish or pinkish maggots about one-fourteenth inch in length that infest opening buds, either killing them or causing the leaves and blossoms to be more or less deformed. The maggots become full grown in five to seven days, leave the buds and complete their transformation in the ground. In the summer the total life cycle is completed in about two weeks. As a rule the maggots are most troublesome during June and July. This insect is more injurious to roses grown under glass than in the open.

Treatment.—This is a difficult pest to eradicate once it has become well established in a greenhouse. Rotation with some other crop, such as violets, may be practised to advantage. Fumigation with hydrocyanic acid gas in March, when the growth of the maggots is slow, will be found of value in killing the flies before egg-laying. Fumigation does not give so good results in the summer. It is a good plan to watch the plants carefully and to pick off and destroy all infested buds. See the florist's statement on this pest, page 3017.

ROSE SCALE (*Aulacaspis roseæ*).—Snow-white nearly circular scales, about one-tenth inch in diameter, encrusting the branches. More troublesome when roses are grown in partial shade.

Treatment.—Spray with lime-sulfur solution, one gallon in eight gallons of water, while the plants are dormant. It may also be advisable to cut off the worst infested stems.

ROSE CURCULO (*Rhynchites bicolor*).—A bright red snout-beetle, with black legs and snout, which appears on the rose-bushes early in June, eating holes into the unopened buds and puncturing the flower-stems. Some of the injured buds fail to open, while others have the petals riddled with holes. The grubs feed within the buds and young fruit and in late summer descend to the ground where they spend the winter as pupæ.

Treatment.—In the garden continued hand-picking of the beetles will be found effective. In larger plantings, arsenate of lead, two pounds in fifty gallons of water—one ounce in one and one-half gallons—will destroy many of the beetles. As the beetles breed in the fruit of the wild rose, these plants should not be permitted to grow in the vicinity of the rose-garden.

ROSE SLUG-CATERPILLAR (*Euclia indeterminata*).—Occasionally in the South roses are subject to the attack of a caterpillar of striking appearance, about $\frac{3}{4}$ inch in length, orange in color, and covered with tufts of spines.

Treatment.—In small plantings the caterpillars may be picked

off by hand. While doing this work gloves should be worn, as the spines of the caterpillar emit an irritating fluid. In larger plantings the caterpillars can be controlled by spraying with arsenate of lead as recommended for the preceding.

FULLER'S ROSE BEETLE (*Aramigus fulleri*).—Small grayish brown snout-beetles about $\frac{1}{2}$ inch in length which are often very destructive to the foliage of roses grown in the greenhouse. The white, curved grubs, about $\frac{1}{2}$ inch in length, burrow in the soil and feed upon the roots of the plant.

Treatment.—Persistent hand-picking should be practised to prevent the pest from gaining a foothold in the greenhouse.

MEALY BUGS.—These common greenhouse pests are sometimes injurious to rose plants. They may be controlled by syringing the plants with tobacco extract, or a stiff stream of water may be used to dislodge them.

THRIPS.—Minute yellowish or orange insects about one-thirtieth inch in length which often injure the opening blossom-buds of roses grown under glass. They may be controlled by spraying with tobacco extracts or by the use of a sweetened poison made according to the following formula: Water, twelve quarts; paris green, one tablespoonful; sugar, three pounds.

C. R. CROSBY and M. D. LEONARD.

Rose diseases.

POWDERY MILDEW, caused by the fungus *Sphaerotheca pannosa*, is one of the most common and injurious diseases of roses wherever they are grown. It is usually first noticed as grayish or whitish spots on the young leaves or shoots. Later, as the spots enlarge, they have a white, powdery appearance, a felt-like coating being formed, especially about the thorns. The young leaves, stems, and buds are dwarfed, curled, or variously deformed. Injured leaves soon drop, and growth and flower-production is seriously interfered with. Frequently the young buds themselves are attacked by the fungus, rendering the flowers worthless.

Treatment.—(1) Under glass. Thoroughly dusting with sulfur, or spraying with potassium sulfide, one ounce to three gallons of water, every ten days is often sufficient. Ammoniacal copper carbonate is also effective. Vaporized sulfur, produced either by boiling sulfur in a pot over an alcohol lamp, or by painting the heating-pipes with equal parts of sulfur, lime, and water, can be successfully used. No time should be lost in applying one of these treatments as soon as the mildew appears. Burned sulfur is likely to injure the plants. As one of the conditions favorable to the spread of mildew is dry, cool air, such as would come into the greenhouse from ventilation, broken glass, or open door, care should be taken to eliminate all drafts. (2) Out-of-doors. Outside, rose mildew can be controlled by dusting with finely ground sulfur. Frequent applications should be made, starting with the first appearance.

BLACK SPOT, caused by the fungus *Diplocarpon roseæ* (more commonly known as *Actinonema roseæ*), is the most common and injurious disease aside from powdery mildew. Roses grown both out-of-doors and under glass are affected. The disease is most destructive during the summer. The more or less circular spots may attain a diameter of a centimeter or more, are of a black color, and are characterized by an irregularly fringed border. The spots occur on the upper surface of the leaf, and by confluence may involve the entire surface. Frequently the leaves become yellow, both in the invaded and uninvaded tissue. Defoliation soon takes place. Bushy sorts are more susceptible than the climbing varieties.

Treatment.—The fungus lives over winter on fallen leaves. Therefore, the source of spring infection will be eliminated by gathering and burning all the leaves either late in the fall or early in the spring before the buds expand. However, this is not sufficient entirely to control the disease. It is recommended that the plants be sprayed as soon as the disease becomes manifest, several applications at intervals of a week or ten days being sometimes necessary. Bordeaux mixture is said to be effective but is objectionable in that it coats the foliage. As a spray of ammoniacal copper carbonate is just as effective and lacks this objectionable feature of bordeaux mixture, it is to be given the preference.

ROSE RUST, caused by the fungus *Phragmidium* (several species), has been reported occurring on indoor and out-of-door roses. It is abundant on wild roses. The disease manifests itself in early spring as orange powdery patches on leaves, shoots, and buds. Frequently the greater portion of the surface of the leaf may be covered. The patches on the wood are often large, and distortion or curving of the part affected may occur. Toward autumn, black pustules are to be found on the under side of the leaves and on the stems, the latter of some varieties being killed to the ground.

Treatment.—All fallen infected leaves and all diseased plants or plant parts should be collected and burned. Spraying with potassium sulfide has been recommended, but further experimentation with this fungicide is desirable.

STEM CANKER, caused by the fungus *Coniophyrium vernsdorffæ* (probably the same as *C. fuckelii*). Cankers are formed on the canes and branches, being characterized by a brown center with a black border, outside of which is a reddish zone.

Treatment.—Diseased canes should be cut and burned.

CROWN-GALL, a bacterial disease caused by *Bacterium tumefaciens*. The disease occurs on plants grown in the open and under glass and is characterized by galls or tubercles being formed on the stems or roots, or both.

Treatment.—Removal or sterilization of the soil by steam, thorough disinfection of the benches, and so on, is the only remedy to be suggested. Rejection of all stock showing any indication of galls is advisable.

DOWNY MILDEW is caused by the fungus *Peronospora sparsa*. It is particularly a disease of greenhouse roses, and is of somewhat rare occurrence. The disease is characterized by wilting and rapid killing of young leaves.

Treatment.—Dusting with sulfur is held to be effective against this disease.

L. M. MASSEY.

ROSE ACACIA: *Robinia hispida*. **R-Apple:** *Eugenia Jambos*. **Rosebay:** *Nerium*. **R. Campion:** *Lychnis Coronaria*. **R., Christmas:** *Helleborus niger*. **R., Japanese:** *Kerria japonica*. **R. Mallow:** *Hibiscus*. **Rosemary:** *Rosmarinus*. **R. of China:** *Hibiscus Rossiniensis*. **R. of Heaven:** *Lychnis Celsi-rosa*. **R. of Jericho:** *Anastatica*, see *Resurrection Plants*. **R. of Sharon:** *Hibiscus syriacus*. **R., Rock:** *Cistus* and *Helianthemum*. **R., Sun:** *Helianthemum*.

ROSELLE. An annual hibiscus (*H. Sabdariffa*, page 1485, Vol. III), cultivated in tropical and subtropical regions for the acid of the immature calices and involucrels or bracteoles; known also as red sorrel and Jamaica sorrel; it also yields a fiber.

The roselle is used in the making of an acid drink and also for jellies, jams, sauces, and marmalades, being a good substitute for cranberry and currant in regions where these fruits do not grow. It is grown somewhat in the southernmost parts of the United States. The culture is essentially that of the eggplant. Seeds are sown in a seed-bed, and the young plants transferred to rows in the field far enough apart to allow of horse-tillage, and $1\frac{1}{2}$ to 2 feet apart in the row. The plant usually grows 4 to 5 feet high if not too highly fertilized, and produces a bush of many stalks. No special tillage or care is required. Before the bolls are woody or stringy, they are broken off by hand. They may be utilized fresh, or dried for future use. The common forms of roselle are rich red and make very attractive products; the yellowish forms appear not to be grown in this country. The yield of one plant may be three to sixteen pounds.

ROSMARINUS (Latin, *sea-dew*; the plant is common on the chalk hills of the south of France and near the seacoast). **Labiatae.** **ROSEMARY.** Hardy evergreen shrub; a well-known garden plant, with aromatic leaves used for seasoning.

Leaves narrow, entire, with revolute margins: fls. in short axillary racemes, few, approximate, opposite, subsessile, bluish or white; calyx ovoid-campanulate, 2-lipped, posterior lip concave, minutely 3-toothed, anterior 2-cut; corolla-tube exserted, limb 2-lipped, posterior lip erect, emarginate or shortly 2-cut, anterior spreading, 3-cut, the midlobe largest, concave, declined; perfect stamens 2: nutlets smooth, ovoid-subglobose.—One species, *Medit.* region. The genus is placed near *Salvia*, being distinguished by the calyx being only shortly 2-lipped, not hairy in the throat and the connective of the anthers continuous with the filament and indicated only by a slender reflexed tooth.

Rosmarinus officinalis has small light blue flowers, which are much sought by bees. Oil of rosemary, a volatile oil distilled from the leaves, is a common preparation in drug-stores. The leaves are also used in making Hungary water. In northern herb-gardens, it lasts for years if given well-drained soil and some winter protection. It is recommended for hedges in southern California, especially for dry and rocky places near the coast.

officinalis, Linn. **ROSEMARY.** **OLD MAN.** Shrub, 2-4 ft. high: lvs. numerous, linear, with revolute margins: fls. axillary, in short racemes, borne in early spring. V. 3:61. **Var. prostratus**, Hort. (*R. prostratus*, Hort.), is distinguished from the type by its prostrate habit.—A good plant for dry positions on the rocky.

F. TRACY HUBBARD.†

ROTHRÓCKIA (named for Prof. J. T. Rothrock). *Asclepiadaceae*. Perennial twining herb hardy in the southwestern United States.

Stems somewhat woody at base: lvs. opposite, cordate-acuminate, long-petioled: infl. loose axillary

cymes; fls. white; calyx 5-parted; corolla rotate, deeply 5-cleft, the lobes oblong; crown simple, inserted at the junction of the corolla and stamen-tube, 5-parted: follicles thickened, acuminate, smooth.—Three species, N. W. Mex. and Ariz.

cordifolia, Gray. Lvs. opposite, slender-petioled, cordate, acutely acuminate: fls. white or whitish, in racemes; corolla-lobes 3-4 lines long. N. W. Mex. along water-courses near the borders of Ariz. and also in Ariz.—Cult. in S. Calif. F. TRACY HUBBARD.†

ROTTBOËLLIA (Christen Friis Rottboell, a Danish botanist, 1727-1797). *Gramineae*. Annual or perennial, usually robust grasses of the tribe *Andropogoneae*, found mostly in warmer regions of the world. The species furnish some forage but they are scarcely horticultural. Spikelets in pairs as in *Andropogon*, awnless, arranged in cylindrical spikes, more or less embedded in the axis, the first glume coriaceous and covering the excavation of the rachis-joint. The genus is more properly referred to *Manisuris* by recent authors, this name being taken up on technical grounds.

A. S. HITCHCOCK.

ROUPALA (probably a native name in Guiana). Also spelled *Ropala*, *Rupala*, *Rhopala*. *Proteaceae*. Trees, smooth or ferruginous-tomentose, suitable only for the warmhouse.

Leaves alternate, leathery, stiff, entire or dentate, undivided, or those of the sterile branches (and younger trees?) pinnate: fls. in axillary or terminal racemes, pedicelled in pairs, perfect; perianth cylindrical, slightly dilated at base, the limb scarcely broader, subglobose, oblong or elongated, finally laxly revolute; ovary sessile: caps. hard, oblique, 2-valved, short-stipitate.—About 40 species, Trop. Amer.

A. Hairs rust-colored.

Pöhlia, Meisn. (*R. corcovadensis*, Hort.). A tree, with branches clothed with rusty colored woolly tomentum: lvs. 1 ft. or more long, pinnate, with 5-8 pairs of lfts. which are 3-5 in. long, on stout petioles 1 in. or less long, ovate or obliquely ovate, acuminate, acutely serrate: fls. $\frac{1}{2}$ in. long, white or yellowish, in nearly sessile axillary racemes 3-5 in. long. B.M. 6095.

AA. Hairs golden.

aurea, Lind. According to Belg. Hort. 1866:202, this species was named for the golden hairs covering the upper parts of the st. and petioles. Brazil.—Rare and imperfectly known.

R. Jönghel, Hort., is a plant offered by Siebrecht which does not appear in botanical works.

F. W. BARCLAY.

F. TRACY HUBBARD.†

ROUPËLLIA: *Strophanthus*.

ROYAL FERN: *Osmunda regalis*. **R. Palm:** *Oreodoxa regia*.

ROYENA (named for Adrian van Royen, of Leyden; died 1779). *Ebenaceae*. Evergreen trees or shrubs suitable for the warmhouse.

Leaves alternate: infl. axillary; fls. small, hermaphrodite; calyx deeply 5- (rarely 4-) lobed, often accrescent in fr., lobes more or less pubescent or silky; corolla campanulate or urceolate, 5-cleft, lobes obtuse, reflexed; stamens 10 in one rank; ovary conical, pubescent: fr. globose, ovoid or oblong, leathery, indehiscent or splitting.—About 20 species, natives of Trop. and S. Afr. The genus is distinguished from the 4 or 5 other genera of the ebony family by the fls. being hermaphrodite instead of dioecious and the stamens in a single series.

Royena lucida is one of the old-time Cape shrubs formerly cultivated under glass for ornament in England and lately offered in southern California. It has small white flowers about $\frac{1}{2}$ inch across, with five more or less reflexed lobes.

lúcida, Linn. Tender evergreen shrub, 4-12 ft. high, or a small tree: bark nearly smooth, dusky gray or whitish: lvs. oval or somewhat ovate, leathery, shining above, more or less hirsute beneath: fls. solitary, axillary, white or yellowish; calyx 5-toothed; corolla-tube urceolate, limb reflexed, 5-parted, puberulous; segms. rounded: fr. ovoid or subglobose, red or purple and fleshy when ripe. S. Afr. B.R. 32:40.

ROYSTONEA: *Oreodoxa*.

F. TRACY HUBBARD.

RUBBER PLANTS. Various plants furnish rubber. The best gutta-percha is said to be produced by *Isonandra Gutta* (which see), a native of India. For the rubber tree of South America, see *Hevea brasiliensis*. The rubber tree of tropical Africa is *Landolphia florida*; see B.M. 6963. The rubber plant of horticulturists is *Ficus elastica*. For an agricultural account of rubber, see "Cyclopedia of American Agriculture," Vol. II.

RUBIA (Latin, *red*; referring to the color of the dye extracted from the root). *Rubiaceæ*. Mostly hardy herbs, sometimes shrubby at base, of little horticultural worth, but one, *R. tinctorum*, is of economic value.

Plants frequently rather stiff, hispid, or aculeate: lvs. in whorls of 4-8 or very rarely opposite and stipulate, sessile or petioled, lanceolate or obovate, rarely cordate: fls. small or minute, in axillary or terminal cymes, 5-merous; involucre none; calyx-tube ovoid or globose, limb lacking; corolla rotate or subcampanulate; ovary 2-celled or through abortion 1-celled: fr. didymous, fleshy, 2- rarely 1-celled.—About 40 species, Medit. region, Trop. and S. Afr., Temp. Asia, Trop. and S. Temp. Amer. *R. tinctorum* is the dye-plant called madder, the long, fleshy roots of which are ground to powder. Madder is said to furnish a good green fodder if cut the second year when in flower.

tinctorum, Linn. (*R. tinctoria*, Salisb.). **MADDER.** A scandent herbaceous perennial: lvs. 2-4 in. long, sessile or very short-petioled, mostly lanceolate, not cordate, in whorls of 4-6: cymes terminal, paniced, spreading, leafy.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RUBUS (Latin name, ultimately connected with *ruber*, red). Including *Bossèkia*, *Rubacer*, *Oreobatus*, *Batidæa*, and others, but excluding *Dalibarda*. *Rosaceæ*. **BRAMBLE. BLACKBERRIES, DEWBERRIES, RASPBERRIES, and THIMBLEBERRIES.** Low and diffuse mostly woody plants, usually producing canes, grown for the edible fruits, some of the species for ground-cover, and others for the more or less ornamental character of habit, foliage, and bloom.

Trailing, decumbent, ascending, or erect plants, the tips of long growths usually recurving even if otherwise erect, glabrous, hairy or variously glandular, mostly thorny or prickly: sts. usually short-lived and pithy (sometimes semi-herbaceous): lvs. simple or compound, alternate, the compounding on the pinnate order and the leaflets largely 3 (several in many of the tropical and oriental species): fls. mostly white or rose-colored, usually in corymbs or racemes but sometimes solitary; calyx 5-parted (rarely 3-5-parted), the lobes persistent; petals 5, usually obovate; stamens many, inserted on the torus-rim; pistils many (or sometimes few), closely packed on the torus, usually becoming drupelets but sometimes dry when ripe, the style nearly terminal.—A most variable and perplexing genus, containing perhaps 400 fairly well-marked species and numberless intermediate forms. More than 3,000 species-names have been applied. The genus is particularly strong in Europe, where great numbers of specific names have been made (see Weihe & Nees, *Rubi Germanici*, 1822-7; Focke, *Synopsis Ruborum Germaniæ*, 1877; Babbington, *British Rubi*, 1869; Focke, in Ascherson & Graebner, *Synopsis der Mittel-*

europäischen Flora, 1902; Rogers, *Handbook of British Rubi*, 1900, and many other publications). Focke in 1877 described 72 species inhabiting Germany. In 1902 he admitted 87 full species to the mid-European flora. There is also a large extension of the genus in the Himalayan region, about 50 species being recognized (J. D. Hooker admits 41 species in the *Flora of British India*). The species extend eastward into China and Japan. Hemsley, in his *Flora of China*, admits 41 species. In Japan, Franchet and Savatier admit 22 species. In the North American Flora, Rydberg admits 112 species, in 1913, counting those in Mexico and southward and excluding certain species that are referred to other genera. Students of the American forms should consult the recent writings of Blanchard, Brainerd, Bicknell, and Rydberg. There is no agreement as to the number of species in N. Amer. or elsewhere, and recently other genera have been segregated. *Rubus* is widely distributed in the northern hemisphere, particularly in temperate and warm-temperate parts. Some of the species are alpine and arctic. In tropical climates the genus is relatively poorly represented. Oliver admits only 4 in the *Flora of Tropical Africa*. Only 2 species are described in Grisebach's

3486. An English raspberry-blackberry hybrid. (X $\frac{3}{8}$)

Flora of the British West Indies. Baker admits 3 species in the *Flora of Mauritius* and the Seychelles. Hillebrand describes 3 species in *Flora of the Hawaiian Islands*. The southern hemisphere has few species. Bentham's *Flora Australiensis* has but 5 species. Cheeseman's *Manual of the New Zealand Flora* mentions only 4 indigenous species. There are also 5 species described in Harvey and Sonder's work (*Flora Capensis*) on the flora of the Cape of Good Hope region. In his *Species Ruborum* (Bibl. Bot. parts 72 and 83. 1910-14), Focke describes 429 or more species from all around the world.

The genus *Rubus* tempts the species-maker. The lines of demarcation are obscure or indefinite, the variables are numberless, the botanical characters differ widely on old and young canes and even on spring and autumn foliage of the same cane, and the plants respond readily to conditions. There are marked shade-forms and sun-forms, moisture-forms and dry-land forms, apparently only environmental modifications of prevailing types. The tendency, therefore, on the one hand is to recognize a very few stem-types as species (Bentham reduced all the British rubi of the blackberry

type to one species, *R. fruticosus*), and on the other hand to make species of the marked departures (Rogers makes more than 100 species and many varieties of the "Rubi fruticosi" of Britain). The herbarium usually provides few checks; the student needs constantly to supplement his specimens with careful observations in the field under many varying conditions, if he is to arrive at an independent judgment on the group. We do not yet know how far the older herbarium definition corresponds with phylogenetic facts. There is indication that rubi hybridize freely, particularly in the blackberry group, and artificial hybrids are produced easily; but to assume hybridity from the herbarium specimen alone is inconclusive, particularly when we have now learned that intermediateness is not a proof of hybridity and that hybrids may even show little departure from one or the other parent. If to the variableness of plants

3487. *Rubus Chamæmoros*.—The cloudberry ($\times \frac{1}{2}$). No. 1.

in the wild is to be added the variation under cultivation, the difficulties are intensified if one endeavors to name and separate very closely; and if very many species are to be made, then it may be practically impossible to identify the horticultural forms with any of the minutely defined wild species. This difficulty is likely to be little taken into account in the usual study of wild material, and yet it is an obligation of the systematist to serve the horticulturist; it would be a pity if the feral and domesticated forms were not studied harmoniously. If one is to abandon the older practice of describing the main stem-types, then the logical procedure is to name and describe all the marked forms with a Latin name. This procedure, however, relegates the group to the knowledge of the close

specialist and confuses the subject for others. Whether in certain groups of Rubus, particularly in the blackberry or Eubatus section, we are dealing with a range of hybrids between relatively few species or whether we have a wide range of plastic material out of which marked forms and incipient species are developing by mutation or otherwise, is the question of primary importance to the systematic study of the genus. The long-established habit of species-making naturally leads to the assumption that specific types occur in all genera and that the variations are to be explained on the theory of intermediateness or aberrance; but this hypothesis is yet to be demonstrated. Of course, the difficulties in cultivated Eubatus are not insolvable by careful study in herbarium, garden, and field.

With these points of view before us, the reader will scarcely expect to find in this account an evaluation of all the species-names that have been given to American rubi in recent years. This task may be undertaken at another time, but it would be of little avail when considering merely the horticultural forms. In assembling the American cultivated blackberries into one group in the following account and the cultivated dewberries into another, it is not intended to pass on the merits, from the systematic point of view, of any of the

several described species; but in the present state of the case, it is impossible to refer all cultivated forms to the species-names now current, nor is it the purpose of the Cyclopaedia to describe all wild species. There is no practicable alternative but to group the horticultural forms at least until such time as the subject is cleared up; and this is done under Nos. 60 and 61. The history of these domesticated groups affords little aid in determining botanical origins, both because the records are themselves imperfect and because the American species had not then been studied critically; the problem must therefore be worked out mostly as a current systematic study.

Rubus is closely allied to Rosa, from which it differs chiefly in the structure of the flower. In Rosa, the torus or hypanthium is hollow and contains the dry fruits or achenes. In Rubus the torus is convex, conical or elongated, and bears the mostly soft or pulpy fruits on its surface. Rubi are chiefly shrubs with stems (canes) that die after one or two years, but some of them have herbaceous tops. In raspberries and blackberries, the canes bear the second year and then die or become very weak. The fruit is an aggregate of carpels. The drupelets are usually more or less coherent at maturity, the collective body forming the "fruit" or "berry" of horticulturists. In the raspberries, the coherent drupelets separate from the torus at maturity, causing the berry to be hollow or concave on the under side. In the blackberries, the coherent drupelets adhere to the torus, which separates at maturity and forms the "core" of the berry. Usually the tops are not long-lived, and commercial plantations require frequent renewal.

The horticultural and controlled hybrids in Rubus are now many. Raspberry-blackberry crosses have been frequently effected, but they appear to have little popular interest. The illustration (Fig. 3486) shows a hybrid between Fontenay raspberry (*R. idæus*) and "the common blackberry" of England as shown by Veitch at London in 1897 (G.C. Oct. 2, 1897, from which the illustration is reduced). The fruits were described as of a purplish black color with gray bloom, produced abundantly.

Relatively few of the rubi have horticultural merit, although some of them are of great importance. As pomological subjects they are more important in North America than elsewhere. Here are grown not only raspberries, which are popular elsewhere, but also great quantities of improved blackberries, a fruit that is less known as a regular cultivated product in other countries. Although the European raspberry, *R. idæus*, is grown in North America, it is mostly unreliable, and the leading commercial sorts are produced from the native *R. occidentalis* and *R. strigosus* and from hybrids of the two. Various Japanese species also produce fruits of value, but none of them has attained much importance in North America.

Numbers of the species are useful as ornamental subjects, particularly the Rocky Mountain *R. deliciosus*, the brier rose (*R. rosæfolius* var. *coronarius*), wineberry (*R. phænicolasius*), and *R. crataegifolius*. For its graceful finely cut foliage, and sometimes for its fruit, *R. laciniatus* is frequently grown, particularly in the milder climates where it is practically an evergreen. Some of the unimproved wild species are offered by dealers in native plants as worthy subjects for free borders and rock-gardens. The beauty of most shrubby rubi depends largely on the removal of the canes after they have bloomed once. After flowering, the cane becomes weak or may die outright. It should be removed to the ground. In the meantime other canes have arisen from the root, and these will bloom the following year. That is, the stems of rubi are usually more or less perfectly biennial: the first year they make their growth in stature; the second year they throw out side branches on which the flowers are borne; after fruiting, the entire cane becomes weak or dies. Removing

these canes not only contributes to conserve the vigor of the plant, but it also adds to its appearance of tidiness. These remarks apply particularly to the cultivation of raspberries, blackberries, and dewberries. For other accounts, see *Blackberry*, *Dewberry*, *Himalaya Berry*, *Loganberry*, *Lowberry*, and *Raspberry*, at their respective entries.

In recent years, many of the Chinese species of *Rubus*, mostly in the subgenera *Malachobatus* and *Ideobatus*, have been introduced to cultivation for ornament, some of them with promise of providing desirable edible fruits. Many of them make long vine-like canes and are excellent for training to posts, pillars, on pergolas and arbors. The foliage is often very ornamental and several of them have white or bluish white canes that render them useful for winter effect. Some of the species are evergreen. These oriental rubuses are known in cultivation mostly in England, but are being tested in this country, particularly at the Arnold Arboretum, Boston; at the latter place, none of the species has proved to be perfectly hardy. The following species have survived, although mostly much killed back each winter: *R. flosculosus*, *R. Lambertianus*, *R. lasiostylus*, *R. Giraldianus*, *R. mesogæus*, *R. innominatus*, *R. adenophorus*; *R. conduplicatus* and *R. teledapos* stood the winter of 1915-16.

The species of *Rubus* require no special place or care in cultivation except to provide in a general way the conditions as to moisture and exposure under which the plants grow in the wild. They are plants of wide adaptability. Propagation is by dividing the clumps in some cases, but better by the use of the natural stolons; or if artificial practices must be employed, root-cuttings 2 or 3 inches long may be used for many species. They are grown readily from seeds.

A. *Species herbaceous or essentially so, small, the flowering shoots arising from the crown of the plant.*

Section I. CHAMÆMORUS. Stamens numerous: fr. juicy: fls. dioecious, borne singly on upright leafy stalks: lvs. simple, lobed. The cloudberry or bake-apple-berry of arctic or subarctic regions, and much prized for its frs., belongs here. No. 1.

Section II. CYLACTIS. Fls. perfect or polygamous, singly or several together at the ends of the shoots: lvs. ternate or pediform (5-parted), or sometimes only lobed. Nos. 2-6.

AA. *Species shrubby: flowering shoots arising from woody canes of 2 or more years' growth, the plants small or large but usually large.*

B. Plant spineless.

Section III. DALIBARDASTRUM. The species here described are prostrate and spineless, woody, brown-hairy: lvs. simple, evergreen, cordate: fl.-sts. erect, the fls. large and white. No. 7.

Section IV. ANOPLOBATUS (*batus* is Greek for bramble). Upright rather soft-wooded shrubs, usually with shreddy bark, large, lobed lvs., large erect fls., and broad torus. Nos. 8-11.

BB. *Plant spine-bearing (exceptions in some blackberries).*

Section V. MALACHOBATUS. Climbing or prostrate shrubs with entire or palmately lobed seldom compound lvs. and mostly not showy fls.; stipules broad, fugacious. Nos. 12-24.

Section VI. IDEOBATUS. Raspberries, with the coherent drupelets separating from the torus; upright or ascending shrubs, with simple or ternate lvs., small lfts., and drooping fls. in mostly short clusters; stipules linear to lanceolate. Nos. 25-55.

Section VII. EUBATUS. Blackberries and dewberries, with the drupelets adhering to the torus when ripe; stipules linear. Nos. 56-66.

Section I. CHAMÆMORUS.

1. *Chamæmorus*, Linn. CLOUDBERRY. BAKEAPPLE-BERRY. YELLOW BERRY. MOLKA. SALMONBERRY improperly (see No. 32). Fig. 3487. Creeping: branches herbaceous, covering the ground, pubescent or almost glabrous: lvs. round-cordate or reniform, shallowly 3-5-lobed, finely dentate: fls. large and white, in solitary terminal peduncles: fr. large, globular, red or yellowish, composed of few soft drupelets, edible. Entirely across the continent in high northern and arctic regions, and reaching as far south, in the E., as the high land of Maine and N. H. and eastern end of L. I.; also in Eu. and Asia.—The cloudberry is an inhabitant of peat-bogs and cool places. It is much prized for its fr., which is gathered from the wild in large quantities. It is sometimes planted farther south as a rock-garden plant. *R. arcticus*, Linn., a pink-fl. species with trifoliate lvs., occurs in nearly the same range, and produces small edible berries; this species belongs to Section II.

Section II. CYLACTIS.

2. *pubescens*, Raf. (*R. americanus*, Brit. *R. triflorus*, Rich.). Sts. slender and trailing, 1-2 ft. long, herbaceous, without prickles, glabrous or nearly so: lvs. thin and soft, light green, with 3 or 5 ovate or rhombic-ovate, coarsely serrate lfts.: fls. 1-3 on each peduncle, small and white, the calyx reflexed: fr. small, reddish. Cold swamps, N. J. west and north.—Offered as a rock-garden plant for moist places.

3. *pedatus*, Smith. Low creeping unarmed herbaceous coptis-like perennial, rarely cult., probably adapted to cool woods or rock-gardens: lvs. pedately 3-5-foliate, with thin obovate or rhombic-obovate irregularly cut lfts. which are glabrous or only sparsely

hairy on veins beneath: fls. solitary and terminal on short shoots, white, about 1 in. across. N. Calif. and Idaho to Alaska; reported in Japan.—By Focke referred to the subgenus *Dalibarda*; if kept in a distinct genus, the plant becomes *Dalibarda pedata*, Steph. Interesting as a rock-garden plant.

4. *stellatus*, Smith, produces an edible fr. prized in Alaska, where it is native, as well as in Yukon and Kamchatka: st. simple and herbaceous, only a few inches long, 1-fl'd.: lvs. cordate, 3-lobed or 3-parted, reniform in outline, pubescent on both sides or glabrate in age, simply or doubly serrate: fls. solitary and terminal, rose-colored: fr. red, globose, with 20 or more drupelets, said to be known locally as a dewberry.

5. *xanthocarpus*, Bur. & Franch. (*R. Potaninii*, Regel). Trailing, the sts. dying back every year, the sts. pilose and weak-spiny: lvs. pinnately 3-foliolate, the lfts. ovate, acute or obtuse, strongly and unequally dentate, the terminal one twice larger than the others: fls. solitary or twin in the axils of the upper lvs., the peduncle and calyx weak-prickly, the petals white: fr. large, ovate, bright yellow, fragrant, and palatable, the calyx persistent. China; discovered in 1885 in the Province of Kansu, 40° north latitude, and later found in provinces Szechuan and Yunnan.—Intro. into the U. S. in 1898 by the Dept. of Agric. through N. E. Hansen, to be tried for its edible raspberry-like fr. It is said to provide a good cover; fairly hardy in Minn; it appears not to have found favor in this country and its value is doubtful.

6. *simplex*, Focke. Small plant, 1-2 ft., making a roundish densely branched bush; sts. simple, puberulous, sparingly bristly: lfts. 3, hairy above, puberulous on the veins beneath, unequally mucronate-serrate, 2-4 in. long, the lateral ones short-stalked, the terminal on a stalk $\frac{3}{4}$ -1 in. long: fls. axillary, few, short-pedicelled, white, over $\frac{3}{4}$ in. across; petals scarcely exceeding the triangular acuminate sepals: fr. edible, orange-red. Cent. China. H.I. 20:1948.—Probably useful as a subject for rock-gardens.

Section III. DALIBARDASTRUM.

7. *tricolor*, Focke (*R. polytrichus*, Franch., not Prog.). A distinct dwarf species with prostrate spineless brown-yellowish-hairy sts., growing several feet in a season under moist shady conditions: lvs. simple, about 3 in. long, cordate, evergreen, sharply toothed, dark green above but with rows of hairs between the chief veins, white-tomentose beneath and with brown bristle-hairs on the rib and chief veins: fls. white, 1 in. across, on erect fl.-sts.: fr. rather large, bright red. W. China, up to 10,000 ft.—Probably worthy as a wild-garden and rock-garden subject.

3488. *Rubus deliciosus*, from the Rocky Mountains. (No. 9.)

Section IV. ANOPLOBATUS.

A. Lvs. mostly 7-lobed.

8. *trifidus*, Thunb. FIRE RASPBERRY. Strong-growing and erect, 7-10 ft. tall: lvs. large, palmately ribbed, 3-5- or even 7-cleft, serrate: fls. subsolitary, the peduncles villous: berry of medium size, scarlet, with pointed

3489. Clump of *Rubus odoratus* (flower $\times \frac{1}{2}$). No. 10.

drupelets. Japan.—Sparingly intro. and prized for its bright autumn foliage (whence the name "fire raspberry").

AA. Lvs. 5- or less-lobed.

B. Peduncles mostly 1-fl'd.

9. *deliciosus*, James (*R. Roëzlii*, Regel. *Bossèkia deliciosa*, A. Nels. *Oreobatus deliciosus*, Rydb.). ROCKY MOUNTAIN FLOWERING RASPBERRY. Fig. 3488. Compact, bushy grower, reaching 5 ft.: lvs. large, orbicular or reniform, shallowly 3-5-lobed, unequally serrate, somewhat glandular: fls. borne in great profusion, pure white, 1-2 in. across, in early summer and continuing for a long season: berry hemispherical, purplish or wine-color, with larger, soft drupelets like those of a red raspberry, edible but not esteemed for eating. Cañons in the mountains of Colo., reaching 8,000 ft. elevation. B.M. 6062. G.C. II. 15:537. R.H. 1882, p. 356; 1903, p. 447. F.S. 23:2404. Gn. 18:358; 29, p. 336; 34, p. 231; 45, p. 74; 46, p. 293; 73, p. 64. Gt. 47:1451; 52, pp. 355, 356. Gng. 3:325. G.M. 41:508; 45:143. G. 2:491; 8:650; 36:411, 777.—The finest of native flowering raspberries, and deserving to be widely known. Hardy in Mass. The fls. resemble single roses.

BB. Peduncles several- to many-fl'd.

10. *odoratus*, Linn. (*R. grandifolius*, Salisb. *Bossèkia odorata*, Greene. *Rubacer odoratum*, Rydb.). FLOWERING RASPBERRY. MULBERRY (erroneously). Fig. 3489. Strong-growing plant, with the shreddy canes reaching 3-6 ft.: lvs. very large, pubescent beneath, 3-5-lobed, the lobes triangular-acuminate with broad triangular teeth and sharp-serrate: fls. 1-2 in. across, rose-purple, several to many in the cluster, the sepals with a long point, the peduncles and pedicels glandular-pubescent: berry flattish and broad ($\frac{3}{4}$ in. across), rather dry, light red, edible but not valued. Nova Scotia to Mich. and Ala. Gn. 34, p. 230. B.M. 323. J.H. III. 31:133. F.E. 22:557. Var. *columbianus*, Millsp. (*Rubacer columbianum*, Rydb.), native in W. Va., has lanceolate incised-dentate or doubly dentate lobes. Var. *albidus*, growing with the type, has whitish fls. and lighter-colored bark.—*R. odoratus* prefers rich shady woods and banks. It makes a bold subject in a foliage mass, and its fls. are nearly as large as many single roses, although the color is less bright. It spreads rapidly from the root and overtops weaker plants.

11. *parviflorus*, Nutt. (*R. nutkanus*, Moç. *R. lacer*, Kuntze. *Bossèkia parviflora*, Greene. *Rubacer parvi-*

florum, Rydb.). Differs from the last in having white fls. in few-fl. clusters and less glandular peduncles. N. Mich. to the Pacific Coast and southward in the Rockies; the western representative of *R. odoratus*. B.M. 3453. B.R. 1368. Gn. 45, p. 75; 59, p. 61; 62, p. 249; 67, p. 255.

Section V. MALACHOBATUS.

A. *Lvs. compound* (in *R. Henryi* 3-lobed *lvs. sometimes occurring*).

12. *Hénryi*, Hemsl. & Kuntze (*R. bambusàrum*, Focke). Evergreen, with trailing shoots 10–15 ft. long, with few spines and gray-tomentose when young: *lvs.* 3-lobed and of 3 lfts. often on same branch, rarely of 5, the lfts. long-lanceolate, 3 in. or more long, minutely and more or less distantly toothed, tomentose beneath: fls. small, pink, in terminal racemes 2–3 in. long: fr. $\frac{1}{2}$ in. or less diam., shining black, not unpleasant in flavor. W. China, 4,000–7,000 ft. altitude. G.C. III. 42:251; 51:148. G. 28:630.—A handsome plant for pillars and pergolas, because of its graceful growth and interesting foliage. It has been considerably advertised abroad.

13. *Playfairii*, Hemsl. (*R. Playfairianus*, Hort.). A rambling or diffuse shrub, evergreen, with thin wire-like sts. which bear small curved spines and are cobwebby when young: *lvs.* of 3–5 linear-lanceolate or lanceolate serrate lfts., the terminal one 5–7 in. long, all bright green above and gray-felty beneath, the stipules $\frac{1}{2}$ in. long and cut: fls. $\frac{1}{2}$ in. across, in irregular clusters, the petals shorter than calyx-lobes: fr. black, of fair or moderate flavor. China. G.C. III. 51:166.—Makes a handsome plant when trained up on stakes.

AA. *Lvs. not compound, although sometimes lobed*.

B. *Infl. terminal and racemose, simple; peduncles solitary*.

14. *malifolius*, Focke. Sts. prostrate or climbing, woody, with few short curved prickles: *lvs.* simple, oval or oblong-elliptic, coriaceous, 2–5 in. long, broadly but shallowly toothed: fls. 1 in. across, in short terminal racemes: fr. rather large, black, flavor unpleasant. W. and Cent. China.—Said to be an elegant species with handsome fls. Named for its apple-like *lvs.*

15. *hupehensis*, Oliver. Deciduous, with prostrate terete sts. somewhat gray-flocculent when young, with very short curved prickles: *lvs.* simple, oblong-lanceolate, about 3–4 in. long, acuminate, rounded at base, serrate, gray-tomentose beneath, short-petioled: fls. 3–7, in a terminal short raceme. Cent. and W. China. H.I. 19:1868. A related species is *R. Swinhöii*, Hance, which is evergreen: *lvs.* ovate: fr. black, rather bitter. China. G.C. III. 51:166, under this name, appears to represent *R. hupehensis*.

BB. *Infl. variously paniculate or thyrsoid, the peduncles mostly fascicled (except perhaps in No. 20)*.

C. *Lobes of lvs. none or usually not prominent (partial exception in No. 19), the lvs. not mallow-like*.

16. *chroosépalus*, Focke. Strong-growing shrub, with slender sts. which bear few spines: *lvs.* simple, cordate-ovate, 4 in. long and nearly as broad, linden-like, glabrous above, tomentose beneath: fls. in large loose panicles, apetalous, the reflexed sepals colored inside: fr. small, black. Cent. China. G.C. III. 51:166.—Advertised abroad; evergreen probably in mild climates, but sometimes described as deciduous. Useful on posts and pergolas for its habit and foliage.

17. *ichangensis*, Hemsl. & Kuntze (*R. eugénius*, Focke). Sts. long and slender, with few small prickles, evergreen: *lvs.* simple (the older ones sometimes more or less 3-lobed), broad-lanceolate, cordate at base, 3–4 in. long, light green on both surfaces, remotely toothed, long-petioled: fls. very small, in small panicles: fr. small, red, of good flavor. Cent. and W. China, to

7,000 ft. altitude. G.C. III. 48:275.—The *lvs.* have a metallic luster.

18. *Párkeri*, Hance. Slender evergreen, with long scandent softly glandular-hairy sts. which bear short curved spines: *lvs.* simple, broad-lanceolate or ovate-lanceolate, 3–5 in. long, cordate at base, irregular or angled on the sides, rugose, dark green above, velvety-pubescent beneath: fr. black. China. G.C. III. 51:166.

19. *Lambertiàus*, Ser. Sts. long and slender, quadrangular, with few hooked spines, evergreen: *lvs.* simple, 3–5-lobed and more or less angled, 3–4 in. long, bright green but becoming colored in autumn, glabrous above, slightly hairy and light green beneath: fls. small, whitish, in terminal clusters: fr. red, and apparently sometimes yellow. China. G.C. III. 48:276; 51:166. Var. *glàber*, Bean. Differs in having terete sts., uniformly yellow fr., and *lvs.* and sts. glabrous or nearly so.

3490. *Rubus crataegifolius*
($\times \frac{1}{4}$). No. 27.

CC. *Lobes of lvs. usually prominent, and the lvs. mallow-like*.

D. *Sts. herbaceous or only half-shrubby*.

20. *irenàus*, Focke. Unarmed or with very small prickles, with slender creeping sts., evergreen: *lvs.* simple, nearly orbicular, 5 or 6 in. either way, cordate at base, slightly 3–5-lobed, white-tomentose and rusty along the nerves beneath, glabrous and metallic green above: fls. $\frac{1}{2}$ in. or more across, the petals roundish, white, exceeding the sepals: fr. yellow. Cent. China, 4,000–8,000 ft. altitude.—Probably useful in mild climates and moist places for covering slopes.

DD. *Sts. shrubby*.

21. *omeiënsis*, Rolfe (*R. clémens*, Focke). Unarmed shrub with branches arching and 10–20 ft. long: *lvs.* palmately lobed, 4–5 in. across, hairy beneath: fls. small, rose-colored, in long and narrow panicles: fr. black. It makes long straggling growths lying on the ground and rooting freely: unarmed: *lvs.* shortly 5-lobed or obscurely 7-lobed, 7–9 in. across either way, glabrous above and hoary beneath: fls. small, with purplish petals. W. China; bears the name of Mt. Omei.

22. *flagelliflorus*, Focke (*R. flagelliformis*, Hort., not Smith). Evergreen or nearly so, of attractive habit, 8 ft. or more, the sts. and under surface of *lvs.* duntomentose, the spines few: *lvs.* simple, cordate, acumi-

nate, irregularly serrate, 4-5 in. long, deep metallic green on upper surface: fls. white, on growths of 6-8 in. long: fr. medium in size, glossy black. Cent. and W. China, 4,000-6,000 ft. R.B. 33, p. 360.—Useful on posts and pergolas.

23. *moluccanus*, Linn. A large raspberry-like plant in many forms, common in India and Malaya, and to be expected as an intro. plant in many warm countries. Very robust, the tomentose canes and branches red-hairy and with short curved scattered prickles: lvs. simple, very variable, large, usually hairy, gray- or yellow-woolly beneath, mostly broad-ovate or orbicular and deep-cordate, shallowly 3-5-lobed, irregularly serrate: fls. white, in contracted terminal clusters: fr. in shades of red, succulent. Gn. 63, p. 408. G.M. 46, p. 323. —Probably not in the American trade.

3491. *Rubus spectabilis* of western America.—The salmonberry. (No. 32.)

24. *reflexus*, Ker. Tall stout climber sometimes confused with *R. moluccanus*: prickles few and scattered: young growth, petioles, and under surface of lvs. bearing cinnamon-colored pubescence: lvs. simple but sometimes prominently 3-5-lobed, broad-ovate or ovate-oblong in outline, base cordate, margins toothed, prominently nerved beneath, the terminal lobe long: fls. white or pink, $\frac{3}{4}$ in. or less diam., nearly sessile in small few-fl. declined clusters: fr. small, globular, red-purple or black. China. B.R. 461. B.M. 7716. Var. *pictus*, W. Wats., has the lvs. velvety green, and gray-variegated above and soft pale cinnamon-brown beneath: handsome. G.C. III. 33:309 (as *R. moluccanus*). R.B. 29:237.

Section VI. IDÆOBATUS. Raspberries.

A. Lvs. simple, often 3-lobed on strong shoots.

25. *corchorifolius*, Linn. f. Nearly or quite erect, 4-6 ft., the terete sts. downy and bearing small straight spines: lvs. simple, cordate-ovate, mostly 3-lobed on the verdurous shoots, 4-7 in. long, dull green above and pubescent beneath, the margins coarsely toothed, midrib and petiole with hooked prickles: fls. white, solitary, on short lateral twigs: fr. bright red, large, said to be excellent in quality. Cent. and W. China, to 7,000 ft. altitude. Japan. G.C. III. 51:149.—There are several forms or very closely related species.

26. *palmatus*, Thunb. Spreading, often slender-stemmed plant growing 4-5 ft. tall, with many short, but stout nearly straight spines: lvs. rather small, 2-3 in. long as a rule, narrow-ovate-acuminate or sometimes nearly triangular-ovate-acuminate, rather deeply 3-5-lobed and the middle lobe long and acuminate, the margins very sharp-serrate: fls. white, nearly or quite $\frac{3}{4}$ in. across, with broadly ovate petals: fr. small (red?), of little value. China, Japan. B.M. 7801.—Sparingly intro. as an ornamental plant, but little known here. The Mayberry, intro. by Luther Burbank, is said to be a hybrid between this species and the Cuthbert raspberry (*R. strigosus*). The Mayberry is described as producing a large yellow edible berry, ripening in advance of the strawberry. *R. palmatus* is doubtfully referable to *R. microphyllus*, Linn. f.

27. *cratægifolius*, Bunge. Fig. 3490. Strong, erect or diffuse much-spreading plant (3-5 ft.), with terete reddish glabrous canes that bear few and small straight spines: lvs. oblong-ovate to cordate-ovate, acuminate, 3-5-lobed, and the margin coarsely serrate and notched: fls. white, in small clusters terminating slender leafy shoots, about $\frac{1}{2}$ in. across: fr. small, orange-red, of no value. China, Japan.—An excellent plant for holding banks and for covering waste places, and giving fine deep reds in the fall. Perfectly hardy in Cent. N. Y.

28. *Savatiéri*, Bailey (*R. morifolius*, Sieb.; Franch & Savat. Enum. Pl. Jap., 1875, not Muell., 1858. *R. cratægifolius* var. *morifolius*, Focke). Differs from *R. cratægifolius* by its more numerous and stronger prickles, the lvs. villous beneath and deeply cordate at base, shorter petioles and shorter and thicker pedicels. Japan.—Offered by dealers in Japanese plants, who speak of its pretty fr. ripening in July.

29. *trianthus*, Focke. Wide-spreading deciduous shrub, glabrous: sts. erect, and much branched, blue-white, prickly, 4-6 ft.: lvs. simple, more or less 3-lobed, 3-6 in. long, ovate to triangular: fls. pink-white, small: fr. dark red, of 10-30 carpels. Cent. China.

30. *conduplicatus*, Duthie, perhaps the same as *R. trianthus*, but described as differing in the pale green (not white) under surfaces of lvs., smaller fls., prickles on st. stronger and more curved. China.—A scandent glandless shrub, with simple petiolate lvs. which are ovate-lanceolate and acuminate and sometimes obscurely 3-lobed, the margins unequally incised-serrate: fls. 3-4, terminal, white.

31. *Koehneanus*, Focke (*R. incisus*, Hort., not Thunb. *R. morifolius*, Hort., not Sieb.). Nearly erect shrub, 3-4 ft. high, the branches with purplish bloom and unarmed or sparingly prickly: lvs. simple, varying from almost entire to 3-5-lobed, 5 in. or less long, and nearly as broad, mostly deep-cordate at base, green above and white-pubescent beneath, the lobes more or less acute, petioles somewhat prickly: fls. few, in loose terminal corymbs, white, the petals about $\frac{1}{4}$ in. long: fr. small and globose, orange. Japan. B.M. 8246. Gt. 53, p. 555 (as *R. incisus*).

AA. Lvs. ternately compound, running to 5-foliolate forms, often on the pedate order.

B. Fls. large, solitary or few together.

32. *spectabilis*, Pursh (*Parmena spectabilis*, Greene). SALMONBERRY. Fig. 3491. Strong-growing, reaching 5-15 ft., glabrous: spines few or often none, weak: lvs. of 3 ovate-acuminate lfts., which are doubly serrate-toothed and sometimes indistinctly lobed, long-stalked, thin, glabrous or becoming so beneath: fls. solitary or in 2's, large, red or purple: fr. large, somewhat conical, salmon-color or wine-red, edible, the drupelets bearing the persistent styles. Calif. and Idaho to Alaska. B.R. 1424. L.B.C. 17:1602. F.S. 21:2260. Mn. 4, p. 57.—Sometimes cult. for its showy fls. and frs. Canes perennial. Var. *Ménziesii*, Wats. (*R. franciscanus*, Rydb.), has lvs. densely pubescent or silky underneath.

BB. Fls. medium-sized or small, mostly clustered.

c. Plant profusely red-hairy.

33. *phœnicolâsius*, Maxim. WINEBERRY. Fig. 3492. Canes long and recurving, furnished with straight, weak prickles and densely clothed with red-brown glandular hairs, prop. by "tips:" lfts. usually 3, broad-ovate to round-ovate, apiculate-toothed and sometimes indistinctly lobed at top, white-tomentose beneath: fls. in dense, small, shaggy-haired clusters which spring from the uppermost axils and form a large, loose, leafy panicle; petals shorter than the long, bristly calyx-lobes, the latter enlarging after flowering and inclosing the growing frs. in a bur but spreading apart as the fr. matures: fr. usually small and soft, cherry-red, acid or usually insipid. Japan and China. B.M. 6479. G.C. II. 26:365; III. 11:269; 28:137. J.H. III. 29:210. Gt. 52, p. 565. G. 19:235. A.G. 12:205; 15:435. Gng. 3:263.—Interesting as an ornamental plant, and also recommended for its fr. In the N. it often kills to the ground, but the strong young recurving canes and white-bottomed foliage make it a handsome plant. Sparingly run wild in the E. U. S.

34. *adenôphorus*, Rolfe (*R. sagâtus*, Focke). Resembles *R. phœnicolâsius*: sts. stout, with short red prickles, the exposed parts dark red, densely covered, as are the sepals and petioles, with purple stalked glands: lvs. ternate or the upper ones simple, the lfts. unequal (rarely 5), the terminal largest and cordate-ovate, the lateral subsessile, all dull green above, hairy on both sides: fls. 6-10, in short terminal clusters, rose-colored, the broadly clawed petals about $\frac{1}{4}$ in. long: fr. about $\frac{1}{2}$ in. across, edible, the drupelets red with black tips. China.—The erect red sts. are ornamental in winter and the foliage is ornamental in summer.

35. *ellipticus*, Smith (*R. flavus*, Hamilt. *R. Gowreep-hâl*, Roxbg.). Fig. 3493. Tall and erect or nearly so (6-10 ft.), the canes stout and densely beset with straight red-brown or crimson hairs and bearing a few stout, short, nearly straight prickles: lfts. 3, the terminal one much the largest, ovate to orbicular-ovate, not lobed, evenly doubly serrate, thickish, soft pubescent and strongly veined and prickly on the midrib beneath: fls. white, $\frac{1}{2}$ in. or less across, in small, many-flid. clusters: berry the size of a common raspberry, yellow,

of good quality. Himalayas.—Grown in S. Fla., where it is said to be the only raspberry that perfects its fr. Advertised in Calif. as Golden Evergreen raspberry, and recommended for pergolas and covering sheds. Naturalized in Jamaica.

3493. *Rubus ellipticus*. A yellow-fruited species from the Himalayas ($\times \frac{1}{2}$). No. 35.

cc. Plant not red-hairy all over.

D. Fr. red or reddish at maturity (not described in Nos. 39, 42), sometimes golden (running into yellow and white forms).

E. Infl. usually 1- to 6-flid.

36. *maciléntus*, Camb. Shrub, to 5 ft., the branches bearing strong straight or hooked prickles, the plant glandless and nearly glabrous: lvs. glabrous, with many hooked prickles, the lfts. 3, of which the terminal one is 2 in. or less long and ovate-oblong, the lateral ones small, all doubly toothed: fls. white, usually 3 together on end of short lateral growths: fr. orange, yellow, or red, glabrous, inclosed in the calyx. Himalayan region.

37. *lasiostylus*, Focke. A species apparently of variable forms, having bluish white bristly strong arching sts.: lvs. pinnate, small, silvery white beneath, the lfts. 3-5 and coarsely unequally double-serrate and sometimes 3-lobed: fls. magenta-red, of good size, the petals erect and clawed: fr. rose-color but woolly, sweet but said to be useless for eating. China. G.C. III. 51:167. G. 28:631.

38. *biflorus*, Hamilt. Strong shrub prized in cult. for its glaucous-white canes: reaches 8-10 ft., with arching canes that bear stout, recurved prickles: lfts. 3-5, ovate or oval, incise-serrate, whitish beneath: fls. large and white, 1-3 on drooping pedicels: berry golden yellow or amber-colored, size of the common raspberry, the calyx at first erect, but finally spreading. Temp. Himalaya. B.M. 4678. R.H. 1855:5. Gn. 54, p. 456. Var. *quinqueflorus*, Focke. A striking plant with sts. reaching 12 ft. high and 4-5 in. circum. at base, covered with a waxy white bloom and therefore very showy, the spines stiff and $\frac{1}{2}$ in. long: pinnate lvs. about 1 ft. long, the lfts. about 5 and white beneath: panicles terminal and axillary and about 5-flid., the fls. white and $\frac{3}{4}$ in. across: fr. golden yellow, good. W. China. Gn. 76, p. 624.—A promising fr.-bearing as well as ornamental plant.

39. *Wilsonii*, Duthie. Scandent shrub with terete very spiny brown-purple glaucescent sts., the branches quadrangular and red-purple and more or less winged between the nodes: lvs. pinnate, of 3-5 ovate more or less cordate strongly double serrate lfts. which are glabrous and deep green above and paler beneath and sparsely prickly on the ribs underneath: fls. purple, in axillary and terminal few-flid. fascicles (terminal clusters 4-5-flid., axillary 2-3-flid.), the petals about $\frac{1}{2}$ in. broad and long. Cent. China.

EE. Infl. many-flid., mostly clustered, dense or aggregated.

40. *innominâtus*, S. Moore. Raspberry-like in appearance, with strong upright very soft-pubescent and sparingly prickly sts. 6-8 ft. high: lvs. pinnate,

3492. *Rubus phœnicolâsius* ($\times \frac{1}{2}$). No. 33.

large (often 9 in. long), dark green, grayish white beneath and thickly covered with glands, with 3 or 5 (usually 3) ovate lfts., the terminal one much larger than the others and often 3-lobed: fls. small, pink, in panicles 18 in. long in Sept.: fr. orange-red, edible. Cent. and W. China. G.C. III. 38:291. R.B. 33, p. 360.—*R. Kuntzeanus*, Hemsl., is distinguished by its glandless lvs.; perhaps not specifically separate; the plants in cult. as *R. innominatus* apparently belong to this species.

41. *teléapós*, Focke. Arching or procumbent, with few strong incurved prickles: lvs. ternate or somewhat quinate, opaque above but densely pubescent when young, white-tomentose beneath; lateral lfts. obliquely ovate-lanceolate, acute, coarsely serrate; terminal lft. ovate or ovate-lanceolate, acuminate, sometimes obscurely lobed, coarsely incised-serrate above: fls. many, in a leafless terminal raceme or in few-fl. axillary clusters, rose-colored or purple: fr. red. W. China.

42. *mesogæus*, Focke. Sts. weak or scandent, densely tomentose-pubescent, with small weak prickles: lvs. ternate, slender-petioled; lfts. rhomboid-elliptic or angled-ovate or oblique-ovate, all unequally coarsely serrate, the terminal stalked, broad-ovate, sometimes lobed-dentate: fls. several to many, small, white or rose-colored, the petals obovate and clawed: fr. small, red(?). China.

43. *idæus*, Linn. EUROPEAN RASPBERRY. An erect, mostly stiff grower, prop. by suckers, the canes light-colored and bearing nearly straight slender prickles: lfts. ovate, white beneath, irregularly toothed and notched, usually somewhat plicate or wrinkled: fl.-clusters mostly long and interrupted, most of the peduncles dividing into 2 or 3 pedicels, the pedicels, as also the flowering shoots, petioles, and midribs, finely pubescent, but not glandular, and sparsely furnished with firm recurved prickles: fls. small, white; calyx pubescent: fr. oblong or conical, dark red, yellow or whitish, produced more or less continuously throughout the season. Eu. and Asia.—Named for Mt. Ida, in Greece. Early intro. into this country, but now nearly driven from cult. by the hardier native species. The Antwerps, Fontenay, and Fastolf belong here. *Rubus idæus* is not known to be native to N. Amer., but it is said to be sparingly escaped from cult.

44. *strigòsus*, Michx. (*R. idæus*, Linn., var. *strigòsus*, Maxim. *R. idæus*, subsp. *strigòsus*, Focke). RED RASPBERRY. Fig. 3355, p. 2913. Much like the last, but distinguished by a more slender and open habit,

stiff prickles on the bearing canes which are brown and somewhat glaucous, thinner leaves, and gland-tipped hairs or bristles upon the flowering shoots, petioles, and calyx, the latter less pubescent or hirsute: fl.-clusters more open or scattered: fr. bright light red, or rarely yellow or whitish, not produced continuously. Widely spread in the northern states as far west as Missouri, also in the mountains to Ariz. and northward to Alaska, extending farther north than the Black-cap; also in Asia.—Under cult. the glandular hairs usually disappear. The light red garden berries, like Cuthbert, belong here. Var. *álbus*, Fuller, has amber-white frs.

This plant belongs to a variable group, and other species have been separated from it, as: *R. carolinianus*, Rydb., from N. C., with young sts. puberulent and densely retrorsely glandular-hispid; *R. Egglestonii*, Blanch. (*R. idæus* var. *anóm- alus*, Fern.), from Vt., perhaps an aberrant form, with lvs. of floral branches mostly simple and reniform and somewhat rounded-3-lobed; and others.

45. *negléctus*, Peck. PURPLE-CANE RASPBERRIES. Fig. 3494. A large and variable race of hybrids between *R. strigosus* and *R. occidentalis* occurs both naturally (*Rubus neglectus*, Peck, 22d Rep. Reg. N. Y. State Univ. 53, 1869) and in the garden (Bailey, Amer. Gard. 11:721, 1890). These plants prop. either by "tips" or suckers, usually by the latter. The fl.-clusters are open and straggling, and the fr. ranges in color from yellow to purple. As a rule, the fr. is aggregated at the end of the cluster, but is scattering below. The Purple-Cane type of raspberry belongs here. Prominent varieties are Shaffer, Philadelphia (now nearly out of cult.), Gladstone, and probably Caroline.

DD. Fr. black at maturity (yellow-fruited forms are known).

46. *occidentalis*, Linn. COMMON BLACKCAP. Figs. 3495, 3496. Strong, erect bush, the canes finally recurving and rooting at the tips, furnished with straight spines, glaucous, not bristly; lfts. broadly ovate, dull green above and white beneath, finely and sharply serrate and notched, the petioles usually bearing short prickles: fls. in small, dense, prickly clusters with sometimes a few scattering pedicels, the petals shorter than the long-pointed whitish woolly sepals: fr. rather small, hemispherical, firm or even hard, black or occasionally amber-white, dry and sweet. Plentiful in fields and clearings in the northeastern states and Canada to Ore. and Brit. Col. and southward to Ga. in the mountains, and to Mo.—In cult. known in many forms, as Ohio, Gregg, etc. Var. *pállidus*, Bailey, has amber-yellow fr.; sometimes found in the wild.

47. *leucodérmis*, Douglas (*R. occidentalis* var. *leucodérmis*, Card). Branches often yellow-tinged: lfts. more coarsely dentate-serrate, sometimes nearly incise-serrate, more gradually acuminate, yellowish green above, the prickles strong and more hooked and those of the infl. flattened laterally: fr. reddish black or black. Rocky Mts. and west to the Coast Range.

AAA. Lvs. long-pinnate, usually with 3 or more pairs of narrow lfts.

48. *rosæfólius*, Smith (*R. floribúndus* and *R. sínénsis*, Hort. *R. rosæfórus*, Roxbg.). Erect and tall-growing,

3495. *Rubus occidentalis*. The original of the cultivated black raspberries ($\times \frac{1}{4}$). No. 46.

3494. The Caroline raspberry, a form of *Rubus neglectus* ($\times \frac{1}{4}$). No. 45.

evergreen in warm countries, glabrous or somewhat pubescent-hirsute: lvs. odd-pinnate, the lateral lfts. 2-7 pairs, all the lfts. ovate-lanceolate or lance-oblong, acuminate, strongly many-veined and very sharp-serrate, more or less silky-hairy beneath: fls. solitary or in few-fl'd. clusters, white, $1\frac{1}{2}$ -2 in. across, showy: fr.

3496. Gregg raspberry, a cultivated form of *Rubus occidentalis* ($\times \frac{1}{4}$). No. 46.

erect, bright red, long thimble-shaped, usually about $1-1\frac{1}{2}$ in. high, very showy, edible but insipid. Widely distributed in tropical countries, but native to the Himalayan region and eastward to China and Japan; naturalized in W. Indies. B.M. 6970. F.S. 17:1714. A.G. 20:82, 87. Var. *coronarius*, Sims (*R. grandiflorus*, Hort.), is a double form, sometimes cult. as the "Brier Rose" and "Bridal Rose" (B.M. 1783. G.C. II. 11:77. G.Z. 26, p. 266). The double-fl'd. form is often grown under glass and in pots.

49. *illecebrösus*, Focke (*R. sorbifolius*, Hort., not Maxim.). STRAWBERRY-RASPBERRY, Figs. 3497, 3498, from Japan, is a dwarf glabrous but prickly undershrub with pretty pinnate foliage, and white fls. $1\frac{3}{4}$ in. across, and scarlet fr. Gn. 64, p. 412. A.G. 24:603. A beautiful plant and worthy of general cult. In the N. it usually kills to the ground each winter, but it throws up shoots 2-4 ft., and these bloom from summer until frost, usually ripening fr. at the same time. The fr. has some value for eating, but it is probable that it will never be greatly developed in this direction. *R. illecebrösus* is suckering: sts. angular, glabrous, prickly: lfts. 5-7, oblong-lanceolate, acuminate, duplicate serrate, pilose on the veins beneath, otherwise nearly glabrous: fls. terminal and axillary, solitary or few, bracted. How much of the cult. material belongs to this species and to No. 48 is to be determined.

50. *coreanus*, Miq. Of upright or erect growth, with straight prickles on the sts. and hooked prickles on the petioles, self-supporting, 6-7 ft. or more high, the sts. hoary, bluish white and the young growths dark brown: lvs. pinnate, 7-9 in. long, usually of 7 or 9 ovate serrate pointed light green lfts.: fls. rose or purple, in large terminal panicles: fr. said to be of no value. China, Korea. G.C. III. 51:149.

51. *amabilis*, Focke. Shrub, 6 ft., slightly prickly or unarmed above: lvs. pinnate, with about 9 ovate or ovate-lanceolate, deeply double-serrate lfts. 2 in. or less long, the petiole and rachis weak-prickly, the stipules small and linear: fls. solitary, terminal, large (about 2 in. across), white: fr. large and red, of good flavor. W. China.

52. *flosculösus*, Focke. Erect, about 7 ft., the dark brown sts. bearing stiff prickles: lvs. pinnate, silvery white beneath, with 5-7 lfts. which are distant, lanceolate or narrowly rhomb-lanceolate, serrate, white-tomentose beneath: fls. about 12, small, pale purple, in a panicle, appearing in Sept.: fr. small (size of a pea), dark red becoming black. Cent. and W. China, 4,000-6,000 ft.

53. *thibetanus*, Franch. (*R. Veitchii*, Rolfe). A curious deciduous rubus, said by Focke to represent perhaps the type of a well-marked section in the genus: shrub with terete prickly branches and graceful fern-like foliage: sts. at first erect, but arching with age, blue-white: lvs. 6-9 in. long, pinnate, with 5-11 elliptic or ovate coarsely toothed lfts., puberulous or silky-hairy above and white beneath, the terminal lft. ovate-lanceolate or rhomboid and 2-3 in. long and sometimes almost pinnatifid: fls. rose-purple, in terminal few-fl'd. prickly and pubescent panicles, the orbicular-obovate petals small: fr. globose, red or blue-black, of moderate size. W. China. G.C. III. 51:149.

54. *niveus*, Thunb. Very strong-growing, the sts. reaching 12 ft. and 3 in. circum. with many stiff brown hairs and small spines, arching at the ends: lvs. pinnate, with 3-11 lfts. variable in shape but mostly rhomb-oblong or ovate-oblong, coarsely serrate, whitish-tomentose beneath, the lateral ones scarcely stalked: fls. small, white, many in terminal and axillary panicles: fr. dull black, of medium size. Cent. and W. China, 3,000-8,000 ft. altitude.

55. *Giraldianus*, Focke. Said to be an elegant bush reaching 8-9 ft. in height, the sts. white, branching and gracefully curving above, terete, glabrous, prickly: lfts. usually 7, the terminal ovate-lanceolate, the lateral oblong-lanceolate, unequally coarsely serrate, glabrous above, tomentose beneath: fls. in terminal panicles, 4-5 in. long, small, white: fr. black. N. and Cent. China. Gn. 76, p. 624. G.C. III. 51:147 (as an unnamed species).

Section VII. EUBATUS. Blackberries and Dewberries.

A. *Blackberries: plant usually erect or essentially so (strong canes often recurring and very long ones often repent).*

B. *Species exotic, with mostly perennial canes, and fls. usually borne on the ends of the main shoots.*

56. *thyräsanthus*, Focke. A vigorous species, with suberect or decumbent canes which are prostrate when very long, the strong prolonged sts. angled and

3497. *Rubus illecebrösus*. One of the best flowering rubuses. (No. 49.)

grooved, thorny with flattened declined or curved prickles, mostly thinly hairy or pubescent; petioles and midribs recurved prickly; lfts. 3 or 5, thick, green above and white-tomentose beneath, round-elliptic or round-ovate, the terminal one broad-elliptic or ovate, abruptly pointed, sharply and mostly doubly serrate-dentate: infl. thyrsoid-paniculate, narrow, short or elongated, sometimes compound, densely pubescent or tomentose, leafy; fls. about medium size, white, the small reflexed sepals white-tomentose: fr. black.—Germany, and probably scattered by cult., regarded by Focke as one form of the collective species *R. thyrsoides*, Wimm. Inserted here because the plant grown in this country as the Himalaya berry (p. 1492) is perhaps referable to it.

57. *Linkianus*, Ser. St. angled with many very strong and sharp hooked prickles and mostly finely pubescent; petioles and midribs strongly prickly; lfts. 3-5, oval or elliptic and acute, strongly and mostly doubly toothed, green and nearly or quite glabrous above but white-tomentose beneath: infl. short-paniculate, beset with strong prickles and often more or less leafy, pubescent or tomentose: fls. mostly double, white, the petals obovate and about $\frac{1}{8}$ – $\frac{1}{2}$ in. long: fr. black.—Species founded on garden specimens, the native country being unknown. It is said to be sometimes escaped from cult. and occurs now and then on ballast. A similar plant (not double-fl.) occurs under apparently feral conditions from Md. to Fla., and from this race the Tree blackberry or Topsy, a very thorny variety intro. some years ago as a fr.-plant, seems to have come. This American plant has been confused with *R. cuneifolius*, but differs in its very different foliage. This group is much in need of careful study; Focke regards it as one of the forms of *R. thyrsanthus*. The plant sometimes grown as *R. fruticosus flore alboplena* and *R. spectabilis*, Hort. (not Pursh), probably belongs here or with the following.

58. *ulmifolius*, Schott (*R. fruticosus flore roseoplena*, Hort. *R. bellidiflorus*, C. Koch). Sts. or canes

curving-prostrate or scandent; prickles stout, compressed, dilated at base, straight or on the branches deflexed or falcate: lvs. of 3 or 5 lfts., the petiole armed, stipules linear; lfts. coriaceous, small, unequally sharply serrate, glabrous and somewhat rugose above, tomentose beneath, the terminal one obovate or cuneate-obovate to nearly orbicular: infl. elongated, leafy at base, tomentose and prickly; fls. of medium size, with

3499. *Rubus laciniatus*
($\times \frac{1}{2}$). No. 59.

reflexed unarmed tomentose sepals and red broad-obovate or suborbicular petals, sometimes double: fr. black. Eu.; sometimes grown for its evergreen foliage and in the form with double red or pink fls.

59. *laciniatus*, Willd. (*R. fruticosus* var. *laciniatus*, Hort.). CUT-LEAVED or EVERGREEN BLACKBERRY. Fig. 3499. A tall, straggling bush with permanent or perennial canes in mild climates, and lvs. more or less evergreen, the sts. provided with recurved prickles: lfts. 3, broadly ovate in general outline, cut into several or many oblong or almost linear sharply toothed divisions, the ribs prickly below and the petioles strongly so: fls. in terminal panicles, white or bluish, the calyx and pedicels pubescent or even tomentose: fr. usually thimble-shaped, late, black, often excellent. Gn. 21, p. 57; 45, p. 78. G.M. 49:765.—This blackberry is probably native to Eu., where it has been long known in gardens. It is apparently only a cut-lyd. form of the European *R. vulgaris*, Weihe & Nees. It is now widely scattered, and seems to thrive particularly well in Hawaii and other Pacific islands and on the Pacific slope. By some it is supposed to be native to the South Sea Isls. (see Bull. 64, Utah Exp. Sta.). It is probable that the plant has been intro. into the W. from those sources, but such fact does not prove its original nativity. It has aroused considerable attention in Ore. and other parts of the W., and has been known as the Oregon Everbearing blackberry. In mild climates the lower parts of the canes often live from year to year until they become as thick as one's wrist; and in such climates the lvs. persist for the greater part of the winter. The plant has long been grown for ornament in the eastern states, but it has not attracted attention as a fr.-plant in this region. The fruits are of fair size and quality, and ripen from midsummer or late summer to Oct. The plant is a good ornamental subject, although it is likely to cause trouble by sprouting at the root.

BB. *Species-group of native American origin, with essentially biennial canes: fl.-clusters from lateral shoots as well as terminal.*

60. **Cultivated American blackberry.** A large group of confused or at least undetermined origin, developed within 50 to 75 years from native American species: mostly erect and thorny plants, the canes commonly tall and more or less recurving at the ends: lfts. 3-5, from ovate-acuminate to rarely nearly

3498. *Rubus illecebreus*. Sometimes known as strawberry-raspberry. ($\times \frac{1}{2}$)

broad-lanceolate, usually pubescent and hairy on the ribs beneath: infl. on elongated raceme-like cluster of which the center or terminal fl. is commonly the oldest (the long-cluster blackberries), or nearly as broad as long, due both to shorter axis and longer lower pedicels (short-cluster blackberries), sometimes with small lvs. intermixed (leafy-cluster blackberries), the rachis and pedicels usually glandular-pubescent but in some forms

3500. *Rubus allegheniensis* ($\times \frac{1}{2}$). No. 60.

nearly or quite glabrous: fr. various, from long and thimble-shaped to ovoid or nearly globular.—The more or less well-recognized wild native species-types, variously defined and re-defined, from which some or all of the prevailing pomological blackberries are probably derived, are as follows: *R. argutus*, Link, an erect or stout species with very prickly stiff sts., lvs. relatively small or medium-sized with short-pointed lfts. and thorny stalks and ribs, mostly not glandular short infl., a prevailing group widely distributed from Canada to N. C. and Iowa; with this group are probably to be associated *R. anniculus*, *R. Andrewsianus*, *R. floricomus*, Blanchard, and perhaps *R. pergratus* and *R. orarius*, Blanchard.—*R. floricus*, Tratt., a tall species with branches often decumbent or strongly recurving and stout curved prickles: lfts. mostly narrow and acuminate, somewhat pubescent beneath: infl. loose and leafy, with few fls.: fr. elongated, the drupelets small. Va., south and west. With this, *R. betulifolius*, Small, and *R. lucidus*, Rydb., are probably to be associated.—*R. frondosus*, Bigel., of medium height, mostly erect but sometimes recurving, the prickles straight only slightly curved: lfts. broad, becoming glabrate above, velvety-pubescent beneath: infl. short, villous, with a few simple lvs. or bracts. Canada to Va. and Kans. To be associated with this group are *R. recurvans*, *R. arundelanus*, *R. philadelphicus*, *R. Rossbergianus*, Blanchard, *R. Brainerdii*, Rydb.—*R. allegheniensis*, Porter (Fig. 3500; also Fig. 578, Vol. I). Of medium height, erect but more

or less recurving, the mostly stout prickles moderately curved: lfts. ovate, often cordate, glandular-pubescent beneath: infl. mostly elongated and not leafy, glandular-hairy. Canada to N. C. and Ill. With this group are to be associated *R. nigrobaccus*, Bailey, *R. sativus*, Brainerd, *R. glandicaulis*, Blanchard.

The wild thornless blackberry, *R. canadensis*, Linn. (*R. Millspaughii*, Brit.), is a tall mostly weak-caned entirely thornless species apparently not represented in domestication, the frequent so-called thornless forms of cult. blackberries being apparently unarmed offshoots of normally thorny kinds; this readily distinguished species, with narrow thin mostly glabrous lfts., is native in Canada and the northern states and in the higher lands to N. C.; here are to be associated *R. Randii*, Rydb., and perhaps *R. elegantulus* and *R. amicalis*, Blanchard.

The sand blackberry, *R. cuneifolius*, Pursh, growing in dry fields from Conn. to Fla. and La., appears not to be in cult. or to have contributed to the admixture of the garden blackberries. (Fig. 581, Vol. I.) It is a stiff and thorny plant, usually not over 3-4 ft. tall, the prickles many, mostly hooked, and very strong, the young growths white-tomentose: lfts. on bearing canes mostly small and thick, wedge-oblong to wedge-obovate, obtuse or nearly so, densely white-tomentose beneath, the margins sharp-toothed: fl.-clusters 4-10-fl., short, more or less leafy and thorny, the fl.-buds globular and pubescent: fr. medium in size, firm, often sweet and good. See discussion under *R. Linkianus*, No. 57.

AA. Dewberries: plant trailing or strongly decumbent (often trained to stakes or on trellises under cult.).

B. The pomological dewberries of E. American origin.

61. Cultivated American dewberry. A variable group of American origin, from the native species: trailing or prostrate plants, the weak slender canes lying on the ground or sometimes making low mounds, mostly prickly or thorny: lfts. usually 3: infl. short and mostly interrupted or leafy, or the fls. axillary, pubescent or glabrous: fr. blackberry-like.—The native sources of the dewberries are to be sought in the following more or less marked species-segregations; *R. procumbens*, Muhl. (*R. villosus*, Ait., not Thunb.) (Figs. 3501, 3502), of the northeastern states and south to Va., is the prevailing dewberry of open fields away from the Coastal Plain, with canes usually several feet long and usually bearing stout recurved prickles: lfts. usually narrowed at the base, nearly or quite glabrous: fls. in the upper axils. Var. *roribaccus* (*R. villosus* var. *roribaccus*, Bailey) is the Lucretia dewberry type.—*R. invisus*, Brit. (Figs. 3503, 3504; also Fig. 1250, Vol. II). Probably has the range of *R. procumbens*: canes strong and terete, somewhat ascending and often making mounds or piles of canes and herbage, not very prickly: lfts. large, those on the sterile shoots with large simple serratures: infl. dichotomous. *R. geophi-*

3501. *Rubus procumbens*, a common northern wild dewberry ($\times \frac{1}{2}$). No. 61.

3502. *Rubus procumbens*, fruiting branch ($\times \frac{1}{4}$). No. 61.

lus, Blanchard, is to be placed in this group.—*R. Baileyanus*, Brit. (*R. villosus* var. *humifusus*, Torr. & Gray). More slender, little prickly: lfts. mostly broad at base, pubescent beneath: lvs. or bracts in the infl. simple. Northeastern states. *R. arenicolus*, Blanchard, is probably to be associated with this.—*R. Enslenii*, Tratt, Nantucket and L. I. southward, on the Coastal Plain and perhaps westward, is a soft-caned weak plant with small loose black fr. that is probably little if at all involved in the origin of the horticultural dewberries.

BB. *The swamp dewberry or running blackberry.*

62. *hispidus*, Linn. (*R. obovatus*, Michx. *R. sempervirens*, Bigel.). Fig. 3505. Sts. very slender, scarcely woody but usually persisting over winter, creeping, bearing many weak reflexed small bristles: lfts. usually 3, thick, shining above, wedge-obovate or oval-obovate, usually obtuse, doubly serrate: fls. small, white, on few-fl'd., herbaceous nearly or quite leafless peduncles arising from the creeping canes: fr. small and of few drupelets, red to red-black, sour. Swamps or low sandy soils, Nova Scotia to Ga. and Kans.—Of no value for fr., but sometimes offered by dealers for covering the ground in moist places. The lvs. usually persist through the winter, and in sunny places they assume a fine bronzy hue.

3503. *Rubus invisus*, the cultivated form known as Bartel dewberry. (No. 61.)

BBB. *The southern dewberry or running blackberry.*

63. *trivialis*, Michx. SOUTHERN DEWBERRY. A variable and perplexing species, the difficulties being increased by the fact that the same plant may bear 3 kinds of lvs.: the large, broad blackberry-like lvs. on the young verdurous sterile shoots; the smaller lvs. on the canes that are to bear fr. and which often persist over winter and remain at flowering-time; the small lvs. that appear with or somewhat before the fls. It is seldom that the lvs. of sterile and flowering shoots of the same plant are preserved in herbaria. Canes very long, usually wholly prostrate (sometimes 10–15 ft.), thickly armed with prickles and sometimes bearing reddish bristles: lfts. usually 3, narrow-ovate to oblong, short-pointed, rather shallowly and sometimes bluntly toothed, the petiole and midribs usually prickly: fls. of medium size, mostly on simple, more or less prickly

peduncles: fr. usually oblong, sometimes excellent but oftener dry and seedy. From Va. to Fla. and Texas, and in cult. in two or three forms for its fr.—This is the common wild dewberry or running blackberry of the southern states, often a serious pest in old fields, ranging as far north as Va. and west to Okla. What are apparently forms of this species have been intro. for cult. for the fr. in the southern states.

BBBB. *The western dewberries, with mostly pubescent lvs., and fls. often imperfect: species variable.*

64. *vitifolius*, Cham. & Schlecht. (*R. ursinus*, Cham. & Schlecht. *R. ursinus* var. *vitifolius*, Focke). CALIFORNIA DEWBERRY. Widely trailing evergreen, some of the sts. perhaps erect, with slender prickles: lfts. 3 or 5, about 2 in. long, ovate, doubly serrate, some of the upper ones simple or lobed, those on the vigorous shoots usually 3-foliolate: fls. white, the petals of staminate fls. about $\frac{1}{2}$ in. long and of the pistillate $\frac{1}{2}$ in. or less: fr. black, mostly oblong, sweet, the drupelets pubescent. Calif., along streams and moist places.—A perplexing species, by some separated into two: *R. vitifolius*, with lvs. sparingly pubescent on both surfaces and glabrate with age, the st. only slightly hairy, fr. distinctly longer than broad, lvs. on vigorous shoots often unifoliate; and *R. ursinus*, Cham. & Schlecht., with st. and lvs. densely pubescent beneath and fr. only slightly elongate. Certain horticultural dewberries appear to be of this species, but they are of minor importance. The loganberry (which see, p. 1900) is said to be a hybrid between this species and probably *R. idaeus*, but the botanical origin of it is by no means clear. The Phenomenal is said also to have sprung from *R. vitifolius* through hybridization (p. 1900). The Mammoth blackberry of California is said to be a cross between *R. vitifolius* and the wild blackberry of Texas (*R. argutus*?). See Pacific Rural Press, Sept. 4, 1897, for description and portrait. The account says that the Mammoth "produces berries of immense size, supposed to be the largest

3504. Leaf of *Rubus invisus*, from strong shoot, showing the simple dentation ($\times \frac{1}{2}$). No. 61.

blackberry ever grown, berries $2\frac{3}{8}$ in. in length being frequently found. . . . The canes of the Mammoth are very peculiar, being very large and thickly covered with small, short spines. The canes start early in March, grow thick and stout until about 5 ft. high; they then take on a running habit and grow from 25-30 ft. in a season. Late in the fall the tips or stolons seek the ground and take root." The Mammoth is partially evergreen in Calif. The fr. is said to be more acid than the old Lawton blackberry, but "when perfectly ripe is sweet and of superior flavor."

65. *macropétalus*, Douglas (*R. myriacanthus*, Douglas). By many writers combined with *R. vitifolius*, but differs in its glabrous fr., always ternate lvs. which are green and sparingly hirsute on both sides, and larger fls.: it grows in low woods and on stream-banks from N. Calif. to Idaho and Brit. Col.: sts. trailing or

3505. Swamp dewberry.—*Rubus hispidus* ($\times \frac{1}{2}$). No. 62.

scandent, slightly hairy or glabrate, with weak prickles, and prickles on the petioles and midveins: terminal lft. broad-ovate, subcordate, doubly serrate, often somewhat lobed, acute or acuminate; lateral lfts. ovate: infl. slightly glandular, weak-prickly; fls. white; petals of staminate fls. about $\frac{1}{2}$ in. long and those of the pistillate somewhat shorter: fr. half-globular or slightly elongate, black, sweet, about $\frac{1}{2}$ in. long.

BBBB. The exotic dewberry, with long prickly glaucous canes and large very sharp-toothed lfts.

66. *dumetorum*, Weihe. Fig. 3506. Canes long and slender, terete, often 10-25 ft. long, trailing or half-prostrate, glaucous, thickly beset with rather small somewhat curved spines: lfts. usually 3, mostly broad-ovate pointed to acuminate, irregularly sharp-toothed, becoming bronzy and brown in autumn: fls. small, white, the calyx white-tomentose, on short pedicels in a cluster terminating leafy growths of the season: fr. of a few large black drupelets. Eu.—Intro. for the covering of banks and stony places, for which it is highly recommended. Its autumn color is attractive. Hardy in New England.

L. H. B.

RUDBECKIA (after the two Professors Rudbeck, father and son). *Compositæ*. **CONE-FLOWER.** Very attractive summer-blooming perennials or biennials, usually with yellow flowers.

Leaves usually alternate, the blades undivided or in some species much cut, as in the common Golden Glow: fls. both tubular and ray-like, the former usually purplish, the latter always yellow; involucre hemispheric, its bracts imbricated in 2-4 series; receptacle conic or very rarely convex, with chaffy concave scales subtending the disk-fls.; disk-fls. perfect, fertile, their corollas 5-lobed: achenes 4-angled, obtuse or truncate at the apex; pappus none or of 2-4 short teeth.—There are about 31 species, not counting *Echinacea*, all of N. Amer. Of these scarcely a dozen are of horticultural importance. Under *Rudbeckia* are often included in nursery

catalogues certain plants here referred to *Echinacea* and *Lepachys*. These three genera form an interesting floricultural group. *Rudbeckia* and *Lepachys* are typically yellow-fl. genera, while *Echinacea* is predominately rose-purple-fl. The chaff of the receptacle is usually persistent in *Rudbeckia* and deciduous in *Lepachys*. Among the hardy herbaceous species, there are several with striking habit and distinct foliage. There is a wide range of color in the rays of wild plants and many new races are yet to be perpetuated. Some of these with variations in the shape, color, length, color of disk-fls., and so on may serve as the basis of many fine forms. The season of bloom could doubtless be extended. The only full double form, apparently, is the Golden Glow, one of the best perennials of recent intro. Its origin is uncertain, but it appears to be a form of *R. laciniata*. About 1894 John Lewis Childs found it among some plants sent by correspondents. See Gng. 6:370. For structure of the *Rudbeckia* inflorescence or head, see Vol. III, Fig. 1535.

The cone-flowers are of easy cultivation in almost any soil and situation, from a semi-shady position to one in full sun. Most of the species are found inhabiting moist locations, but thrive well in the garden under the ordinary methods of cultivation, although *R. laciniata* and its double form, Golden Glow, do much better if abundantly supplied with moisture. *R. hirta*, the black-eyed Susan,—sometimes called by the children out West "nigger-heads,"—will thrive in the driest hottest situation, where many others would fail. The best known as a garden plant, and probably the showiest, is Golden Glow. If cut back severely when through blooming and well watered, it often produces a second crop of flowers. Autumn Glory will be well liked when better known. It is fine for massing and has a much longer blooming period than Golden Glow, commencing earlier and continuing until frost. It resembles *R. nitida*, an improved form of which, known as Autumn Sun, with bright primrose-yellow flowers, is a splendid acquisition. It grows 5 to 6 feet high, blooming from August to October. *R. triloba* is one of the very best, and, while a biennial, perpetuates itself through self-sown plants. It forms a dense twiggy bush somewhat over 3 feet high and nearly as broad if kept moderately well watered, and much smaller if in a dry situation. These plants may be used with effect as a border to a large bed of hybrid delphiniums, as the latter will tower above them and bloom in their young state. By the time the delphiniums are cut down for their second flowering, the rudbeckias hide their untidiness and are in their prime. The flowers are somewhat like those of the ordinary field black-eyed Susan, but smaller, and much more numerous. While doing best in full sun, they also do remark-

506. *Rubus dumetorum*, an Old-World dewberry ($\times \frac{1}{2}$). No. 66.

ably well in semi-shade, as under overhanging shrubs or in shady corners such as the north side of a house would afford. They like a good open soil. When grown in the open with one stake to the center or main stem, and a string run loosely around the whole plant—being, in fact, a string hoop—catching the larger outer branches to

prevent breakage by the wind at the connection with the main stem, they make a very handsome compact plant. If well soaked at the roots, they may be taken up when in full bloom, and potted in a 10-inch pot, placed in a dark sheltered place over night, and then used for decorative purposes. They remain in good form for a month in a room or on the porch if not in a draft. They may also be taken up carefully and all the soil washed from the roots, and the roots placed in a large vase filled with water, where they present a bouquet arranged as Nature intended. An effective fall-flowering group may be formed by using the lighter-colored flower forms of *Hibiscus syriacus*—such as *Totus albus*, *Lady Stanley*, and *elegantissima*—for a center or background, and interspersing groups of the taller rudbeckias (except *Golden Glow*, which

3507. *Rudbeckia triloba*. ($\times \frac{1}{4}$)

is too tall and spreading) and *boltonias* next to them. In front of these place *R. speciosa* and *R. triloba*, with the blue form of *Aconitum Napellus*, and for a border use *R. bicolor* var. *superba*, placed well to the front to be pulled up when its bloom is past. This group will give color from July until frost. The allied *Echinacea purpurea* and *E. angustifolia* are well adapted for grouping in open bays in shrubby borders, as their flowers are extremely durable and seem in harmony with such surroundings. Rudbeckias are easily increased by seeds, cuttings, or division. (W. C. Egan.)

INDEX.

<i>ampla</i> , 10.	<i>fulgida</i> , 6.	<i>speciosa</i> , 7.
<i>amplexicaulis</i> , 1.	<i>hirta</i> , 5.	<i>subtomentosa</i> , 3.
<i>bicolor</i> , 4.	<i>laciniata</i> , 10.	<i>superba</i> , 4.
<i>californica</i> , 11.	<i>maxima</i> , 9.	<i>triloba</i> , 2.

<i>conspicua</i> , 5.	<i>nitida</i> , 8.	<i>vomerensis</i> , 5.

A. Base of upper lvs. cordate-clasping.

1. *amplexicaulis*, Vahl. Annual, 1-2 ft. high: rays $\frac{1}{2}$ in. long or more, yellow, often with a brown-purple base; disk brownish, finally somewhat cylindrical. Low grounds, La. and Texas. B.B. 3:418.

AA. Base of upper lvs. not cordate-clasping.

B. Color of disk brown or dark purple: shape of disk never cylindrical.

C. Lower lvs. deeply 3-cut.

D. Duration biennial: disk black-purple.

2. *triloba*, Linn. Fig. 3507. Biennial, 2-5 ft. high, bright green: lvs. thin, usually toothed, the lower ones 3-lobed: rays 8-10, deep yellow, base sometimes orange or brown-purple: chaff awned. Moist soil, N. J. to

Mich. S. Ga. to La. and Mo. B.B. 3:415. B.R. 525. G.W. 1, p. 187.—Blooms the first year from seed.

DD. Duration perennial: disk dull brownish.

3. *subtomentosa*, Pursh. Perennial, 2-5 ft. high, ashy gray and densely hairy: lvs. thick: rays 15-20, yellow, sometimes with a darker base: chaff blunt. Prairies, Ill. to Texas. B.B. 3:415.

CC. Lower lvs. not deeply 3-cut.

D. Plants bristly hairy.

E. Rays $\frac{1}{2}$ - $\frac{3}{4}$ in. long.

4. *bicolor*, Nutt. Annual, 1-2 ft. high: lvs. 1-2 in. long: rays yellow, with a blackish purple base or all yellow. Pine woods or sandy soil, Ark., Texas, and east to Ga. Var. *superba*, Hort. Haage & Schmidt, has heads 2 in. across: rays yellow above, purplish brown below. Gt. 47, p. 220. S.H. 2, p. 169. J.H. III. 63:247.

EE. Rays 1-2 in. long.

5. *hirta*, Linn. BLACK-EYED SUSAN. YELLOW DAISY. Biennial or annual, 1-3 ft. high, simple or branched, hispid: lvs. 2-5 in. long: rays golden yellow, sometimes orange at base. Dry and open ground; common over wide range and often rather a troublesome weed. B.B. 3:416. Gn. 49:154.—*R. conspicua*, Hort., is probably only a garden form with long narrow orange-yellow ray-florets and a black disk. Var. *vomerensis*, Hort., differs from the type in having larger fl.-heads with broad ray-fls. which are light canary to golden yellow.

DD. Plants nearly glabrous.

E. Lvs. mostly entire.

6. *fulgida*, Ait. Perennial, 1-2 ft. high: lvs. more or less hairy on both sides, the lower ones 3-nerved: rays 12-14, 1 in. long. Dry soil, Pa. to Mo., south to La. and Texas. B.M. 1996. Mn. 6:221. Var. *compacta*,

3508. *Rudbeckia laciniata*. ($\times$ nearly $\frac{1}{2}$)

Hort., is a dwarf compact-growing form. Var. *variabilis*, Hort., is a form growing about 3 ft. high, with numerous rigid sts.: fls. heads with yellow and brown ray-florets and dark purple disk-florets.

EE. Lvs. irregularly serrate.

7. *speciosa*, Wenderoth. Perennial, 1-3 ft. high: rays 12-20, becoming $1\frac{1}{2}$ in. long. Moist soil, Pa. to Mich., Ark., and Ala. G.C. II. 16:373 (heads 3-4 in. across, rays more than 30, in 2 series). Gn. W. 24:207.

3509. *Rudbeckia laciniata*, Golden Glow. ($\times\frac{1}{4}$)

G. 3:427 (as *R. Newmanii*).—*R. Newmanii*, Loud., is generally considered a synonym of this species.

BB. Color of disk greenish or yellowish.

C. Lvs. entire or barely dentate.

D. Height 2-4 ft.: lvs. bright green.

8. *nitida*, Nutt. This and the next are southern perennials, with lvs. entire or barely dentate: rays drooping, pure yellow, several or numerous; disk finally columnar, 1-2 in. long. Wet ground, Ga. to Fla. and Texas. Gn. 47:201.

DD. Height 4-9 ft.: lvs. glaucous.

9. *máxima*, Nutt. Closely allied to *R. nitida* and differing as indicated in the key. Moist pine woods and plains, Ark., La., Texas. Gn. 47:418. G. 30:281.

CC. Lvs. (upper st.-lvs.) 3-cleft.

10. *laciniata*, Linn. (*R. ampla*, A. Nels.). Fig. 3508. Perennial, 2-7 ft. high: lower st.-lvs. 3-5-parted, upper ones 3-cleft: rays yellow, few or several, soon drooping; disk cylindric in fr. Moist ground, Canada to Fla., west to Mont. and New Mex. G.F. 2:281 (adapted in Fig. 3508). Golden Glow is a full double form, $2\frac{1}{2}$ - $3\frac{1}{2}$ in. across. Fig. 3509. Gng. 5:5, 117; 6:370. A.F. 12:274, 275. Gn. 50, p. 411; 62, p. 305. G.C. III. 20:339.

CCC. Lvs., especially the lower ones, sometimes 2-cleft, very rarely entire.

11. *californica*, Gray. A pubescent, rather rough, simple-stemmed perennial, with the dentate lvs. usually 2-lobed at the base: heads solitary, long-peduncled, composed of numerous rays which frequently exceed 2 in. diam., making a showy fl. nearly 5 in. wide. Pacific coast. J.H. III. 42:281.—One of the best moderate-sized rudbeckias.

R. angustifolia, Linn., is *Echinacea angustifolia*.—*R. Drummondii*, Paxt. (*Obeliscaria Drummondii*, Maund.). Perennial, herbaceous: sts. slender: lvs. pinnate, the lobes linear-lanceolate, slightly jagged, acute: rays large, oblong, obtuse, reflexed, bright orange, deeply stained with dark brown at their base. N. Amer. (?).—Botanically unknown, probably some species of *Lepachys*. P.M. 6:51. B. 5:201.—*R. pinnata*, Vent., is *Lepachys pinnata*.—*R. purpurea*, Linn., is *Echinacea purpurea*.

WILHELM MILLER.
N. TAYLOR.

RÚDGEA (named in honor of Edward Rudge, an English botanist). *Rubiaceæ*. Shrubs or small trees, glabrous or pubescent, suitable for the warmhouse and perhaps hardy in the extreme southern U. S.: lvs. opposite, subsessile or petioled, leathery: fls. medium to rather large, paniculate, sessile or pedicelled, rarely capitate; calyx-tube ovoid or obconical, limb short, 5-rarely 4-cleft or -parted, persistent; corolla smooth or villous, limb 5- rarely 4-lobed, erect or spreading; stamens 5, rarely 4; disk various; ovary 2-celled: fr. small, dry or succulent, with 2 nutlets which are dorsally plano-convex and smooth or sulcate and longitudinally sulcate on their ventral face.—About 115 species, Trop. Amer. *R. leucocéphala*, Schumann (*R. macrophylla*, Benth. *Psychotria leucocéphala*, Brongn.). Lvs. large, subsessile, obovate-oblong: fls. cream-colored, sessile, in fascicles densely clustered in globose heads; corolla-segms. obtuse; peduncles short. Brazil. B.M. 5653. F.S. 17:1720, 1721. G.C. II. 12:81. H.U. 6, p. 257. J.F. 3:292, 293.

F. TRACY HUBBARD.

RUE: *Ruta graveolens*. R. *Anemone*: *Synedemon*. R., Goat's: *Galega officinalis*.

RUÉLLIA (after Jean de la Ruelle, a French botanist). Syn. *Stephanophyllum*. *Acanthaceæ*. Villous, pubescent or rarely glabrous herbs or shrubs, a few species grown under glass and also outdoors mainly in the South.

Leaves opposite, entire or rarely dentate: fls. shades of blue or purple to violet, white, rose to red and rarely yellow to orange, sessile to long-peduncled, axillary, solitary or fascicled or cymose paniculate; calyx deeply 5-cleft or 5-parted, segms. linear or lanceolate; corolla-tube straight incurved or abruptly inflexed, the limb spreading, the lobes ovate or rounded; stamens 4, didynamous: caps. oblong-linear or clavate.—About 200 species, chiefly Trop. S. Amer., a few in N. Amer. and extra-Trop. S. Amer., some in Trop. and S. Afr., Temp. Asia and in Austral.

A. Blossoms sessile or nearly so.

B. Lvs. green.

C. Fls. blue, $1\frac{1}{2}$ -2 in. long.

ciliósa, Pursh. A hardy perennial herb, about $1\frac{1}{2}$ ft. high, erect or prostrate, hirsute or pubescent: lvs. hairy, ciliate, usually oblong, sessile or short-petioled, $1\frac{1}{2}$ -3 in. long: fls. solitary or clustered, axillary, blue, $1\frac{1}{2}$ -2 in. long. Aug., Sept. In dry, light soil, N. J., south and west. B.B. 3:203.—Prop. by seeds or division.

Harveyana, Stapf. Perennial: sts. rather slender, trailing or ascending, 4-angled above: lvs. petioled, green, oblong or elliptic-oblong: fls. produced one at a time in the upper axils, sessile, pale lilac with a white throat and tube; sepals very unequal, 4 linear-subulate, the fifth wide-lanceolate; corolla-lobes elliptic-rounded; ovary glabrous: caps. oblong-lanceolate, not stipitate. Mex. B.M. 8485.

cc. *Fls. rosy, 2-6 in. long.*

macrantha, Mart. It forms a compact, many-stemmed shrub, 1-6 ft. high, with ovate-lanceolate lvs. 4-6 in. long; fls. large, bell-shaped, with tubular base, purplish rose with purple veins, solitary in lf.-axils. Brazil. B.M. 7872. G.C. III. 17:45; 30:467; 43:27. R.H. 1881:410. Gn.W. 5:341; 10:21. Gt. 61, p. 534. G.W. 2, p. 297.—G. W. Oliver says in his "Plant Culture" that *R. macrantha* is of easy cult. and is one of the best greenhouse flowering plants for amateurs. Cuttings rooted in Sept. furnish fair-sized flowering plants in Jan. These, if desired, may be planted out in late spring, when they will have formed large specimens, which may be lifted and potted.

BB. *Lvs. marked with white.*

o. *Fls. white, often veined with lilac.*

Devosiàna, Hort. A low-growing tender Brazilian species, with lanceolate lvs. marked on the upper surface with white along the nerves and having the lower

3510. *Ruellia formosa*. ($\times \frac{1}{2}$)

surface entirely purple: fls. rather small, usually white with blue stripe, axillary; corolla-tube suddenly dilated and bent at the middle. B.M. 8406.

cc. *Fls. carmine or rose.*

Makoyàna, Hort. A compact bushy plant resembling *R. Devosiàna*, Hort., in foliage, but differing in the color of the fls. (bright carmine) and by their somewhat larger size. Brazil. R.B. 21:109. R. H. 1896: 576.—Prefers shade. It is said that the color of the foliage is better when soot is mixed with the soil.

AA. *Blossoms on long peduncles.*

B. *Fls. blue or purple.*

tuberòsa, Linn. A perennial herb, 2-3 ft. high, with oval or ovate lvs. 2-3 in. long and blue fls. $1\frac{1}{2}$ -2 in. long, in terminal, nearly naked panicles; stigmas single: caps. 12-16-seeded. S. W. U. S.; cult. in Fla.

Lorentziàna, Griseb. Glandular herb, little branched, the sts. quadrangular: lvs. decussate-opposite, channeled below, oval, subcordate or attenuate at base, acuminate: infl. terminal in a lax leafy panicle; fls. long-peduncled, usually in 3's, bluish purple; sepals free, linear; corolla funnelform, 5-lobed, rounded, the inferior emarginate; ovary oblong: caps. cylindrical-conical. Uruguay. R.H. 1902:136.

BB. *Fls. red.*

c. *Peduncles much branched.*

amèna, Nees (*Stephanophyllum longifolium*, Pohl). A half-hardy perennial, about $1\frac{1}{2}$ ft. high: lvs. oblong-lanceolate or oblong, narrowed at both ends; margins repand-denticulate or simply repand: fls. bright red, in axillary sprays in summer. Brazil. F.M. 1880:419.

cc. *Peduncles but little branched.*

formòsa, Andr. Fig. 3510. A low-growing, tender, herbaceous perennial: lvs. ovate, rounded at the base, hairy on both sides: fls. on straight, axillary peduncles; corolla scarlet, showy, $1\frac{1}{2}$ in. long, the upper 2 lobes joined for half their length. Summer. Brazil. B.M. 1400.—Cult. in Calif.

R. solitaria, Vell., is offered in the European trade, but its identity is doubtful, as *R. solitaria*, Vell., has been referred by some to *R. Schnaeriana*, Lindau, by others to *R. calvescens*, Lindau.—*R. varians*, Vent., is *Dædalacanthus nervosus*.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RULÍNGIA (after J. Ph. Ruling, a botanist of Göttingen). *Sterculiàceæ*. Shrubs or subshrubs with stellate tomentum or hairs, useful as greenhouse plants and for the rockery in warm climates, as the southern United States.

Leaves entire, toothed or lobed; stipules narrow and deciduous: fls. mostly white, small, in lf.-opposed or terminal, rarely axillary cymes; calyx 5-lobed; petals 5, broad and concave or convolute at base, with a small, broad, or linear ligula at the top; stamens 5 without anthers, linear-lanceolate and alternate with the petals, 5 perfect and opposite the petals; ovary sessile, 5-celled: fr. tomentose or beset with prickles or soft setæ, loculicidally valvate.—About 20 species, all Australian except one from Madagascar.

A. *Lvs. 1-3 in. long.*

pannòsa, R. Br. Eventually a shrub, several feet high, but flowering freely at a young age: lvs. scabrous-pubescent above, densely velvety hirsute below, on older plants ovate-lanceolate to lanceolate, on young plants broader and often 3-4-lobed: cymes shortly pedunculate; fls. white. B. M. 2191.—The plant offered in Calif. as *Pomaderris apetala* is said to belong here. Prized by some for the fleecy coating of its lvs.

AA. *Lvs. usually less than 1 in. long.*

parviflòra, Endl. A low shrub, with branches $\frac{1}{2}$ -1½ ft. long, ascending or prostrate: lvs. ovate or ovate-lanceolate, obtuse, deeply crenate, mostly lobed: fls. pinkish, in shortly pedunculate cymes.—Cult. in Calif., where it is spoken of in high terms as a rock-plant on account of its trailing habit and myriads of small pink fls. borne in spring.

F. W. BARCLAY.

F. TRACY HUBBARD.†

RÙMEX (the Latin name, of unknown origin). *Polygonàceæ*. Dock. Sorrel. Herbs, mostly perennial with strong roots, usually weedy, but some of them afford leaves for "greens," and others are useful for bold effects.

Rumex is closely allied to *Fagopyrum*, the buckwheats, *Rheum*, the rhubarbs, and *Polygonum*, the jointweeds. The rumexes are mostly leafy-stemmed plants, with small fls. in panicles, the pedicels usually in whorls and jointed: fls. perfect or imperfect, with 6-parted calyx (no petals), the 3 inner lobes larger and generally one or all of them bearing a grain or tubercle near the center; these more or less enlarged inner calyx-lobes or sepals are called "valves" in fr.; stamens 6; stigmas 3: fr. a 3-sided often margined or winged achene.—Species probably considerably more than 100, in many parts of the world, some of them on dry land and some in swamps; a few species are widespread weeds in temperate climates, being among the commonest of intro. plants about old buildings and in waste places. They have little horticultural value. Prop. readily by seeds. In the larger species the sts. are grooved and hollow. Most of them are erect-growing plants. See *Dock* and *Sorrel*.

A. *Docks: lvs. not hastate: fls. perfect, or at least not truly diœcious (sometimes polygamo-diœcious).*

B. *Wings of calyx bearing one or more tubercles.*

Patiéntia, Linn. HERB PATIENCE. SPINAGE DOCK. Tall strong erect nearly simple perennial, reaching 5 ft.

when in fl., glabrous: root-lvs. (Fig. 1336, Vol. II) elliptic-ovate, tapering both ways, the margins undulate, the blade 8-12 in. long; st.-lvs. ovate-lanceolate, long-acuminate, more or less rounded at the base: infl. long and compound (often 2 ft. long), dense in fr.: wings cordate, about $\frac{1}{2}$ in. across, veiny, entire, one of them bearing a small tubercle near the base. Eu., but naturalized in many places.—An excellent plant for greens, the strong root-lvs. being used in early spring.

crispus, Linn. CURLY DOCK. YELLOW DOCK. Tall, often 3-3½ ft.: lvs. long-lanceolate, wavy-margined, rounded at the base: valves entire, the tubercles usually 3, the infl. not leafy. Naturalized from Eu., and now one of the common docks about yards and in old fields.—Not cult., but the lvs. sometimes used for greens.

obtusifolius, Linn. BITTER DOCK. A common weed: lvs. much broader, very obtuse or even cordate at base, obtuse at apex, not wavy-margined: valves long-toothed, the tubercle usually 1, the infl. somewhat leafy below. Eu.

BB. *Wings of calyx not tubercle-bearing.*

venosus, Pursh. Perennial, 1½ ft. or less tall, glabrous, branched: lvs. oblong-ovate or ovate-lanceolate, usually tapering at both ends, entire, the stipular sheaths (ochreae) funnel-form and prominent: valves of fr. large and thin, entire, 1 in. or more across, red-veined and showy, the pedicels hanging in fr. Mo., north and west.—Once offered as an ornamental plant because of the very showy wide-winged fruiting calices.

hymenosépalus, Torr. CANAIGRE. RAIZ COLORADA. Erect, reaching 3 ft., glabrous, the root of clustered fusiform tubers: lvs. oblong-lanceolate, sometimes 1 ft. long, narrow at either end, short-petioled, entire, gray-green, somewhat mottled beneath: fls. perfect, large, in crowded panicles, green: fruiting calyx-lobes $\frac{2}{3}$ in. across, brown, entire, veiny, the pedicels drooping. Okla. and Texas to Calif. B.M. 7433.—The plant has some ornamental value, but is of economic importance as a tannin-producing plant, although the supply is insufficient to maintain an industry. The tannin is secured from the dahlia-like roots. For literature on the economic uses of the plant, consult reports of experiment stations in Ariz., Calif., and elsewhere, and Wootton & Standley, *Flora of New Mexico* (Smithsonian Institution).

occidentális, Wats. Stout perennial, reaching 3 ft., glabrous: lvs. lanceolate to ovate-lanceolate, more or less wavy-margined, obtuse or nearly so, the base subcordate, long-stalked: valves of the fr. subtriangular, somewhat toothed, veiny, brown, $\frac{1}{2}$ in. across. Labrador to Alaska, descending along the Rocky Mts. and reaching Texas and New Mex.—Once intro. as an ornamental subject, because of its profuse and somewhat showy fruiting calices.

Hydrolápathum, Huds. GREAT WATER-DOCK of Great Britain and elsewhere in Eu., a stout perennial 4-6 ft. high, with very large lvs., sometimes planted for bold effects along water-courses: lvs. broadly oblong-lanceolate to lanceolate, sometimes 2 ft. long, tapering below but the base often somewhat rounded, acute at apex, the margins crenulate: panicle very large, with rather crowded mostly leafless whorls, the fruiting pedicels jointed near the base and equaling or exceeding the sepals: valves broad, nearly entire, all tubercle-bearing.

AA. *Sorrels: lvs. mostly (at least the radical ones) hastate or sagittate: fls. imperfect, the plants sometimes dioecious.*

B. *Plant annual.*

rhœus, Linn. One to 2 ft., with spreading and branched sts., glabrous and somewhat glaucous: lvs. small, deltoid-ovate, entire, short-pointed, truncate-cuneate or almost cordate at base: racemes short and

leafless or nearly so, the pedicels drooping in fr.: valves cordate-orbicular, $\frac{1}{2}$ - $\frac{3}{4}$ in. across, thin, rosy-veined, without callosities. Egypt to Persia.—Rarely cult. as an ornamental for its showy fruiting calices.

BB. *Plant perennial (R. Acetosella sometimes annual).*

Acetōsa, Linn. GARDEN SORREL. St. strong and erect (3 ft. or more tall in fr.), furrowed, the plant glabrous: root-lvs. thin and light green, oblong and obtuse, with sharp auricles at the base (Fig. 1337, Vol. II), the petioles slender; st.-lvs. relatively narrow, acuminate: infl. large and ample, the larger part of the fls. sterile (plant sometimes dioecious): valves entire or very nearly so, not over $\frac{1}{2}$ in. across, cordate-ovate, each with a callosity near the base, the outer small scales reflexed. Eu. and Asia, and naturalized in some places in this country.—Useful for early spring greens, but later in foliage than *R. Patientia*.

Acetosélla, Linn. COMMON FIELD or SHEEP SORREL. Common in all old fields, where it is taken to indicate sterile or at least unproductive soil: lvs. oblong, from a hastate-lobed base: fls. reddish, in erect racemes. Eu.—Not cult., but the sour root-lvs. are sometimes used for greens.

scutátus, Linn. FRENCH SORREL. Lower, with many branching prostrate or ascending sts., glaucous: lvs. somewhat fleshy, the radical ones long-stalked and cordate-ovate-obtuse, the st.-lvs. short-stalked and hastate-fiddle-form and acute or sometimes 3-lobed: valves thin, cordate, without callosities. Eu., Asia.—Grown in several varieties in Eu., and sometimes cult. in this country for greens. It is a summer sorrel. L. H. B.

RÚNGIA (named for F. F. Runge). *Acanthaceæ*. Creeping, diffuse or erect herbs, glabrous or villous; warmhouse plants: lvs. entire: spikes cone-like; bracts in 4 ranks (whereof 2 alternate are sterile), much larger than the calyx, broad with prominently scarious margins; calyx 5-parted, segms. acuminate; corolla-tube short, straight, limb 2-lipped, posterior lip entire or 2-toothed, anterior often longer, spreading and 3-cleft; staminodia none; disk annular or short-cup-shaped: caps. ovoid or oblong.—About 30 species in the warmer parts of the Old World. *R. eriostachya*, Hua. St. pubescent: lvs. ovate-lanceolate, 2-3 in. long: fls. white and yellow in crowded spikes; the bracts and calices covered with long white hairs. Trop. Afr.

RUPÍCOLA (Greek *rock* and *grower*, presumably referring to its place of growth). *Epacridaceæ*. Shrub: lvs. small, short-petioled: fls. solitary in the lf.-axils, borne on bracteate pedicels which are shorter than the fls.; calyx-lobes 5; corolla 5-cleft, with a very short tube and with spreading divisions which cover themselves in the bud in the form of a quincunx; ovary 5-celled, with numerous seeds.—One species, New S. Wales. The genus is closely allied to *Epacris*. *R. sprengelioides*, Maiden. Shrub 2½ ft. high with twiggy branches: lvs. linear-lanceolate $\frac{2}{3}$ -1 in. long, rigid: fls. solitary, axillary, forming a raceme-like leafy infl. with a barren apex; corolla subrotate, almost $\frac{1}{2}$ in. across, milky white; segms. ovate. B.M. 8438.

RÚSCUS (an old Latin name). *Liliaceæ*. BUTCHER'S BROOM. Erect shrubs with branched partially woody stems, hardy in southern Europe and the southernmost United States.

Leaves minute, bract-like, on lf.-like branches (cladodia) which are alternate, leathery, persistent, and sessile: fls. small, fasciated in the middle of the upper, rarely lower surface of the cladodia, dioecious: berry globose, pulpy, and indehiscent.—Three to 5 species, Eu., Madeira, and Caucasus. The foliage of this plant (Fig. 3511) is composed of lf.-like branches or cladophylls, as in the florists' smilax. Dried, bleached, and

colored sprays (mostly dyed red) are now much used in florists' decorations.

aculeatus, Linn. Shrub, $1\frac{1}{2}$ – $3\frac{1}{2}$ ft. high: phyllodia ovate-lanceolate, $\frac{1}{2}$ – $1\frac{1}{2}$ in. long, tapering into a spiny point: fls. 1–2, short-pedicelled: berry red, $\frac{1}{2}$ in. thick. Spring. Gn. 34, p. 231. R.H. 1984, p. 545.—Cult. in Fla. and S. Calif.

R. androgynus, Linn.=*Semele androgyna*, Kunth.—*R. Hypoglossum*, Linn., has been highly commended in Germany as a decorative subject. This species and *R. Hypophyllum*, Linn., are
